The Tintic mill at Homansville is owned by the Tintic M. & C. Co., of Chicago. It is run by steam, has 10 stamps and 4 pans, 2 settlers and a smelting furnace of 20 tons capacity. The Tintic iron mines are very extensive, and their ores make the best flux found in this Territory. About 150 teams are now engaged hauling it to the railroad for shipment to Sandy and Frisco. Mr. H. M. Green owns a controlling interest in four of these iron mines. He pays from 85 cts. to \$1 per ton for breaking and placing the ore on the dump, where it is sold to the Utah Forwarding Co. for \$2 per ton. His ledges are from 30 to 100 ft. wide, and produce most of the flux now used in Utah smelters. One hundred tons will be the average output from his mines each 24 hours as soon as the roads get in better condition for hauling it away. A. L. M.

### Pinecarte Mining District, San Diego Co.

EDITORS PRESS:—Pinecarte mining district lies immediately north of the Temescal range, in San Diego county. A good wagon road connects it with Colton, 30 miles distant, which is the nearest depot of the S. P. R. R.

This district is comparatively a new one, but the developments now making evidence mines of considerable importance. These ores are, in no case, worked by Mexicans. Some 136 claims have been recorded; six of these prospects are down 35 ft. The veins contain free milling ore, run north and south in decomposed granite; have slicken-sides walls with a dip of 10°. They are easily worked with pick. Width of the veins vary from 2 to 20 inches at the surface and from 6 inches to 3 ft., 30 ft. below.

Gold runs in streaks, some of the quartz being rich, with good showing of coarse gold when horned, others showing but a trace.

Lawshe & White are down 35 ft., drifts north and south 60 ft. This is considered by competent judges to be good for \$250 a ton. The work of prospecting goes on in a lively manner. Several claims have been located on the ledge and more are being staked off.

#### May Queen

Is down 30 ft.; shows free gold. The report obtains that as soon as developments warrant, a mill will be erected.

#### Hoag Mine

Is in by tunnel 75 ft.; differs from others being worked, being in slate. Work is being pushed vigorously, with encouraging returns.

Taylor & Kendle are opening the vein by tunnel and shaft.

Kendle, Crittendon & Co. have just erected a 5-stamp mill which begins work this week. Should the out-look continue favorable, more stamps will be added. Lumber in the district can be had for \$25 per M. Labor commands \$2 per day. Wood, \$3 when delivered. Although mine owners are beginning to make the usual error of asking as much for prospects as mines are worth, yet quite a good opening up is looked for this season.

LEONIDAS TULLY.

April 15, 1881.

### Copper Smelting—Its History and Processes.—No. 2.

[By HENRY HUSSBY VIVIAN, M. P.]

It is indeed a most interesting question, Whence Came the Bronze?

Whether in the shape of celt, sword, spear, brooch, or ingot, which supplied those men with their weapons and ornaments? So far as I am able to form an opinion from the works I have read, I believe that it came from the East, and I agree with Prof. Rolleston in the opinion he expresses in that most able paper which he read before the Bristol and Gloucestershire Archaeological Society, "On the Three Periods Known as the Iron, the Bronze, and the Stone Ages," from which I am largely quoting, and to which I owe many thanks. Prof. Rolleston says: "Whereas was likely to be made the discovery of the advantages to be gained from alloying copper with tin, and so obtaining bronze? It was, of course, likely to be made in some district in which the ores of these two metals were to be found in proximity." When I say I agree in that, I must guard myself against being supposed in any way to assent to the theory enunciated by M. Wihel, that bronze was obtained by the direct fusion of an ore containing tin and copper. I will not detain you by any argument in disproof of what I regard as so absurd an idea; but I do believe that we must look to a district producing ore both of tin and copper as the most likely source of the discovery of bronze. Cornwall is such a district. But I have already stated my reasons for believing that Cornwall was not the primary source from which the bronze of very early ages was derived. No doubt exists that the Phœnicians, who were the great traders in tin between 1500 and 1200 years B. C., visited Cornwall, and purchased its tin, which they carried to the Mediterranean, and possibly also to Northern Europe; but I never heard that there was any reason to suppose that copper formed part of their commerce with Cornwall, nor indeed, as I said before, that copper was produced there in very early days. I think our friend, Prof. Rolleston, who

gave us so much pleasure and information at the meeting of the British Association here this year, has probably hit upon the most probable Source of the Early Production of Bronze, which he details at some length in the 7th, 8th and 9th pages of the paper I before referred to. His first shortly discusses Cornwall, and then turns to "Khorassan;" he tells us that Strabo, who flourished at the commencement of the Christian era, and in recent times Burnes, hinted at the existence of tin in that district, and he tells us that "the late illustrious Von Baer, but 12 days before his death, in 1876, published full and authentic information upon this subject in the *Archiven fur Anthropologie*, derived from a report procured by the Vice-President of the Imperial Geographical Society of St. Petersburg, Herr Semenov, as to the existence of tin, copper, and other minerals near Merv, Herat, and the Banyan pass. This report, which the Professor quotes, seems to establish the existence of rich lodes of tin and copper in that district, and they also state as a fact that many utensils of pure tin are made by the natives for household purposes. Herr Von Baer remarks: "This information makes it highly probable that the tin which enters into the composition of the many bronzes which have been found in Assyrian and Babylonian ruins came from the neighborhood of Khorassan." Prof. Rolleston then goes on to mention a third locality as another and, I think, even more probable source of early bronze, namely, the region lying between Birmah and Banca. He quotes a passage from M. Mortillet, in the *Revue d'Anthropologie*, in 1875, in which he says that "it is evidently there that the origin of bronze must be sought," and he points out the abundance in which tin occurs in the peninsula of Malacca and the island of Banca, together with the

#### Copper Production of the Archipelago.

The Japanese and Chinese both produce copper and cast largely in bronze, even to this day. When and how in the long vista of their history did these arts begin? We know that they regard our era of 1900 years, or that of Rome preceding it by 750 years, as things of yesterday; and we know that advanced civilization had existed among them long ages before Grecian and Roman nations had any existence. Dr. Percy tells us that a book is extant, written in Chinese and Japanese, which gives a most detailed description of copper smelting in Japan, and is illustrated with not less than 100 drawings, showing the perfection to which they had carried that process in early days. The date of the book is unfortunately not given. From the translation quoted, it appears that they go through almost precisely the same processes that we and all other copper smelters of the world go through—that is, roasting and melting the ore, roasting and melting the regulus, blowing it into copper, and refining. But perhaps even more remarkable than this process arrived at and described by the enlightened Japanese long ago, is an extract given by Dr. Percy, from an account of "Hindoo Copper Smelting," written by Mr. H. F. Blanford, of the Geological Survey of India (page 387). He says: "I witnessed the process, here described, in one of the southern valleys of Sikkim Himalayas, a few miles from the Terai. The workmen were Nepaules, by one of whom the little mine was rented from the government." Mr. Blanford then describes the dressing of the ore, namely, pure copper pyrites, which was effected almost precisely as the same operation is performed in Cornwall, and, indeed, in Europe generally, namely, first, a separation of the best from the worst by hand; then, after reducing this ore to a fine state, by washing in a "tye" with water, precisely as in Cornwall and elsewhere. The ore thus "dressed" is melted in a low hearth, the front wall only about six inches high, and the sides about one foot above the furnace-bed. The fuel is charcoal, and the blast is produced by bellows, made of a seamless bag of goat-skin, attached to a nozzle like a blow-pipe, made of clay; these rude bellows were placed one on each side of the hearth, and worked by a boy who alternately loosened and tightened his grasp as he raised and lowered the bellows. The nozzle was inclined downward to within three or four inches of the furnace-bottom. Dr. Percy then proceeds to give extracts from an account published at Calcutta in 1831, of the process of copper smelting carried on at Singhana in India, which appears to be almost absolutely identical with that described by Mr. Blanford in the Sikkim Himalayas, the only difference being that the ore was first mixed with cow-dung, formed into lumps, and burnt for 12 hours in heaps; this roasted ore was then melted at once into coarse copper, which, if the burning had been well done, would naturally be produced, probably with some regulus, which may have been overlooked by the person who wrote the account. The copper was then refined in a small vessel which received the blast of a single bellows. The notice ends with these words: "Copper smelting must have been carried on in this locality during a very long period, as the slags had accumulated to such an extent as to form a line of small hills several hundred ft. in length, and 30 to 60 ft. in height. There were four isolated stony hactions built on one of these artificial mounds."

I have ventured to trouble you at length with these

Accounts of Copper Smelting in the East. Because, as I before stated, I think there is good ground for believing that the production of copper began there in the remotest times, and I think it is most interesting to show that the natives, although utterly ignorant of scientific

metallurgy, yet nevertheless smelted ores of copper and produce that metal on precisely the same principles which prevail to this day in the most scientifically conducted works of Europe. I do not mean to assert that material differences in the appliances used do not exist; but I do assert that the principles involved in their practice and of European copper smelters are identically the same. I have no doubt in my own mind that the systems adopted at the present moment by the Hindoo, Musselman, Japanese and Chinese smelters, in those far regions of the East, are precisely the same as those which their forefathers used in the remotest times. I have no doubt that the copper which went to produce the bronze with which Solomon's temple was adorned nearly 3,000 years ago was smelted in the same way as that now practiced in the East, and that we may probably go back another 3,000 years, to the days of Zillah's son, Tubal Cain, and still with truth make the same assertion as to the process of copper smelting.

I have now dealt with the very early days of copper, the bronze age proper, and that which preceded it. Let us now come to

#### Roman Times.

We know that the, that is, bronze, copper alloyed for the most part with tin, was extensively used. We know that almost every sort of utensil was sometimes made of bronze. I don't very much whether copper, as a pure metal, was largely used even by the Romans. I have seen thousands of Roman bronze castings, but I cannot call to mind having seen one of pure copper. The reason is self-evident. All those objects of common use were cast; pure copper will neither cast sound nor fulfill the requisite conditions of hardness without being rolled or hammered; it is soft, malleable, ductile, but not hard and resistant. I think it also probable that the condition in which it left a Roman refinery, that is, like the German or Russian rosette copper, caused it to be especially unfit to be hammered, as it would be in what we call an "overpoled," and therefore not tough condition, and also very porous. Be that as it may, the fact remains that copper, as bronze, was extensively used by the Romans, and therefore that copper smelting existed at that period on a large scale. Whence did the copper come? We all know the fable that copper first came from the last but, I fear, not the brightest diamond in the British crown, the island of Cyprus, and that it even derived its name from that island; but it is not more probable that this island derived its name from the metal? for language began with man, and we can hardly doubt that copper existed in the far East long before the island of Cyprus received the advancing wave of Eastern civilization, bringing with it probably the name and knowledge of copper. We know as yet nothing of the copper-mines of Cyprus; but we know a great deal too much of the ancient copper mines of Spain. Last year, I visited the famous Rio Tinto and Tharsis mines, and found them covered with mountains of old slags, just as the often prophesied New Zealand may some day wander over and wonder at our Swansea slag-heaps. There is good reason to believe that these workings were Roman, and no one, looking at those heaps, can doubt the great scale upon which they worked, and the skill with which their operations both below and above ground were conducted. They rejected and left unworked the low-produced pyrites, but they followed eagerly the rich veins of yellow ore which traversed these mighty deposits. I saw the wonderful northern "face" of the great "Open Cast" at Rio Tinto, compact pyrites some 80 or 100 ft. deep and 1,000 ft. long, pierced at frequent intervals by ancient Roman galleries, following with true mining instinct the veins of rich ore. I examined critically the slag-heaps, and was astonished at the freedom of the slags, made perhaps nearly 2,000 years ago, from prills. At this moment, with all my accumulated experience of copper smelting, I don't know how they made those heavy iron slags so clean. I had but little time to examine the ground, and I failed to find the remains of their furnaces. I failed also to find metallic bottoms, the famous "Eisensamen," or "iron pigs," which almost invariably accumulate in the bottom of blast furnaces, working on ores of this nature, and which do now occur largely in the most scientifically conducted works of Germany and Sweden. Surely these "old men" knew their business!

(TO BE CONTINUED.)

BORING FOR OIL.—The Santa Cruz Sentinel says: Thousands of dollars are being spent in boring for oil in the mountains back of this city, in this Santa Clara county. Well No. 5, 10 inch bore at top, located in Moody's gulch, one-half mile from Alma, is down nearly 1,500 ft., and reduced to a 4½ inch bore. Well No. 3, is producing oil, some 30 barrels per day, and wells 1 and 6 are being forced down with all profitable speed. The men engaged in the construction and ownership of these wells are mostly old Pennsylvania oil miners, some of them have made and lost their hundreds of thousands of dollars in the oil business, and they express themselves as thoroughly convinced that immense oil deposits will be discovered in the Santa Cruz mountains.

THE MINING AND SCIENTIFIC PRESS, published by Dewey & Co., San Francisco, should be in the hands of every miner on this coast. It is only \$4 per annum and a bound volume for one year is worth twice the money.—Oregon Sentinel, March 5.

## MECHANICAL PROGRESS.

## Hand Skill and Machine Work.

There are plenty of opportunities in all branches of mechanical labor to notice the demand for skilled work in contra distinction to mechanical labor—the difference between the skilled workman and the experienced operator of machine tools. Just now, when mechanical business of all sorts is greatly driven, it is suggestive that in the best shops voluntary workers and would-be apprentices are denied opportunity, and good, experienced men are in demand. One case came under observation recently, where a well-known skillful shop machinist had no less than three good offers, either of which would have been considered, in ordinary times, or state of business, as good. That he was known as a valuable man in the shop, a handy man, capable of "taking a job," gave him a choice in one of three first class establishments. The fact is suggestive to learners—apprentices—and shows them that a merely routine workman is not always sure of employment, and that a sensible, judging and competent workman can make his choice of position and largely influence his remuneration.

There has been so much talk and "blowing" out reproductive machinery and self-acting tools, that it is almost a revelation to know that a skilled workman still holds his own and was at the master of the industrial forces. No inventor or improver can bring his invention or improvement to fruition without his aid; and he who supposes that to run a machine, or operate a tool makes him a thorough mechanic makes his vacation.

There are plenty of opportunities in the shop for the good workman. Indeed, now, when there is such a demand for dispatch in the turning out of finished tools and good machines, the man who can manage a job and bring incongruous parts into a harmonious whole is the man required. Those who can carry out the designs of the draughtsman and the ideas of the inventor are in demand, and in almost every instance of this demand the man is the skilled worker—one who not only understands the design and object of the completed machine, but who also understands perfectly the means to compass the design and secure the object. It is a wonder that so many apprentices are content to slide through their years of apprenticeship with only the ambition to serve their time and with no desire to perfect themselves in their work. There is now—there always is—room for first-class mechanics, workmen who not only run one machine, or handle one set of tools, but who can take a piece of work from inexperience and carry it forward to completion, working and directing in all the stages from the draughting board to the delivery to the purchaser.

In every large shop from whence heavy machinery and tools are sent out there are opportunities for "setting up" and starting, opportunities sought by most shop hands. But these chances are given to men who cannot be baulked by obstacles and difficulties which are sure to present themselves in situations where shop conveniences and handy appliances are lacking. One who understands the entire machine, who is capable of reproducing or finishing or fitting any part, who is a skilled worker and a good mechanic, these opportunities to prove his fitness are welcome and he is accorded privilege and given remuneration denied to those who are content with mere mechanical operation and the running of a machine. There are situations where hand skill with the use of only hand labor, guided by good mechanical judgment, can alone accomplish results, and the workman who is superior to convenient shop appliances shows himself to be a mechanic in the highest acceptance of the term.

These situations may occur in the shop as well as elsewhere, and there are frequent opportunities for the exercise of hand-skilled work in the best of shops. There is not a machine or tool used, however automatic, that was not originated by hand, and there is not one that does not occasionally require hand skill and his guidance for its management and direction. The lathe, planer, milling and shaping machine and other automatic or semi-automatic tools are restricted in their office, and they never escape entirely the control of the skilled hand, guided by the experienced judgment.—*En.*

**CHANGES IN THE RELATIVE ELEVATION OF LAND AND SEA.**—The impression that the northern coast of the American continent is slowly rising, and Prof. Shaler's estimate of the rate of emergence in progress as being over a foot, and perhaps as much as three ft. in a century, has been recently denied by Mr. Henry Schell, who states, in the Coast Survey Report for 1877, that the salt marshes are still, as they were in the time of the early explorers, at ordinary high-water level, and that the rocks on our coast, long notorious as dangerous to navigation, have not risen since they were first discovered. In his statements ancient maps and documents are cited, and the conditions of various rocks are considered in detail. He claims that no tilt in either direction has taken place in the Gulf of Maine. But eastward of latitude 64° 13', and especially in Newfoundland, great changes present themselves in the comparison of charts, the depths appearing at some points less and at other points greater now than formerly.

## New Minerals.

"A New American Gem" formed the subject of a short paper read at a late meeting of the New York Academy of Sciences. The new mineral which constitutes this gem was recently found in North Carolina, by Mr. William E. Widdien. It is of the emerald class, and will be known to the world as lithia-emerald, owing to the presence of lithia as one of its chemical constituents. These gems are described as very beautiful, having a pure green tint, with a liquid brilliancy that is quite distinctive and remarkable. They are selling at about the same price as the diamond. The mineral is found in a narrow chimney in a hard rock formation, geological character not given. The chimney is two feet one way by two and a-half inches the other, and descending at an angle of about seven degrees from the perpendicular.

Another new sideral mineral has also been found by Prof. J. Lawrence Smith while analyzing a meteorite which fell in Emmott county, Iowa, in May, 1879. He has named it Paekhamite, and describes it as essentially different from any mineral heretofore found associated with meteorites. It is a silicate of iron and magnesia, opalescent, of a light greenish-yellow color, of greasy aspect and cleaves scissily. Two or three specimens obtained projected from the outer surface of the stone, with a dingy yellow color and a fused exterior. The meteorite, surrounded by a large number of fragments, lay upon the wet prairie for nearly a year before being discovered, still bright, like a nugget of platinum, and with no appearance of rust.

Still another new mineral is reported, which has been named siderophyllite, in allusion to the large percentage of iron which it contains. In composition it is an iron-alumina mica, and was found near Pike's Peak, in Colorado.

**A NEW SELF-BLOWING FORGE.**—Mr. Eyre, of the firm of Heatfield, Eyre & Co., 158 Leadenhall street, London, England, has invented a self-blowing forge which is well illustrated in *Iron* of February 25th. The hearth and the hood of the forge are of the usual pattern, but underneath the hood is suspended a small steamer. At the top is a safety valve and steam gauge, while at the back of the hearth is a water gauge. A return pipe is brought from the boiler to the tuyre, the water in which becomes pretty well heated before again entering the boiler. At the back of the forge is a small vertical engine with a 2-inch cylinder and 4½-inch stroke, which by means of a grooved fly wheel and endless band, rotates the fan. When lighting the fire the bellows is worked for half an hour by hand, by means of a handle, and during this time sufficient steam will have been generated to drive the engine, which will then work automatically as long as required. The blast is regulated by means of a tap between the engine and boiler. The same engine can also be employed to turn a small lathe, and will really do about one horse-power. It is certainly an ingenious application of the utilization of waste heat.

**RE-ROLLING RAILS.**—But few people are aware of the immense amount of handling that is required to convert an old iron rail into a new one. We were recently a witness to a portion of the operation as performed at the Rolling mills at South San Francisco. From the time the rail arrives at the yard of the rolling mill until it is shipped out it is handled about thirty times. The process is as follows: It is first unloaded from the lighter, then picked up and run to the shears, then cut up, then piled into fagots, then loaded on, to barrow and charged into furnace, heated to a welding heat, then hauled out and placed on iron buggies, run to weighing rolls, where it is handled five or six times, until finished to a bloom, then returned to the buggy, carried to a repeating furnace, brought to a welding heat, then returned to the rolls on a buggy, passed through the rolls eight or nine times, then run to saws where both ends are cut off. It is then placed under the straightener, which takes out all minor crooks. The burr on the ends is then filed off, when the rail is inspected, then taken to the punching machine and fitted for splice bars, thence to the slotting machine, where it is slotted for the spikes; then the rail goes on the benches in the yards and from them to the cars.

**SOMETHING FOR INVENTORS TO EXPERIMENT WITH.**—It is not unusual for a steam fire engine to throw a stream of water from 200 to 300 ft. There is sufficient force employed to throw solid particles from the nozzle two or three times that distance, possibly more. An observer will notice, however, that a stream of water, shortly after leaving the nozzle, begins to spray. The problem is to keep the column of water solid. It has been suggested that the rotary motion of the water causes it to spread, and experiments show this to be the case, but the trouble is only partly avoided by placing flanges within and near the outlet of the nozzle. Is there not some other form of nozzle which will accomplish the result?

**THE TIDES OF ELECTRICITY.**—Mr. Alex. Adams, one of the officers of the British Post-office Telegraph Department, has discovered the existence of electric tides in telegraph circuits. By long continued and careful observation he has determined distinct variations of strength in those earth currents, which are invariably present on all telegraphic wires, following the different diurnal positions of the moon with respect to the earth.

## SCIENTIFIC PROGRESS.

## A Gigantic Artificial Moon.

The colossal representation of the moon, which has been on exhibition at Steinway hall, in this city, during the past week, does not appear to have attracted anything like the attention it deserves. On a half globe, 16 ft. in diameter, the mountains, plains and other characteristics of the lunar surface visible from the earth are shown in relief, with shadings and colorings faithfully representing the moon as seen through a powerful telescope. It is by far the largest, most elaborate and expensive portrait of the moon ever made; and, seeing that it was constructed for and under the immediate direction of one of the most eminent of living eelenographers, Dr. Schmidt, now director of the observatory at Athens, Greece, we may safely accept it as a faithful portrait. It certainly gives at a glance a clearer and more comprehensive idea of the physiography of the moon than could be got by much study with any other means short of a telescope of great power. When gradually lighted from one side by a powerful line light, the varying phases of the moon, from new to full, are shown with impressive vividness.

The shadows of the mountain ranges, the black depths of the crater pits, the changing light upon the broad plains, and other lunar phenomena pass rapidly before the eye, enabling one to obtain in a few hours, indeed in a few moments, a more comprehensive knowledge of the lunar surface than can ever be had of the earth's surface until some enthusiastic geographer constructs in relief a terrestrial globe on a scale of corresponding magnitude.

The "moon" has been purchased and brought to this country for exhibition by Mr. E. Riverston, and it is to be hoped that it will ultimately find a permanent abiding place in some of our public institutions. Meanwhile students of astronomy and all persons taking an interest in science will find the exhibition well worthy of attention.—*Scientific American.*

## Adhesion of Locomotive Wheels.

Since the introduction of steel rails and steel tires of driving wheels, there has been a considerable loss of adhesion. All locomotives are at times short of it. This occurs mostly in the starting of trains and in overcoming the resistance due to curves and high grades of the road. Engineers have been loath to increase the adhesion by loading the driving wheels with a permanent load, for the reason that the extra weight will, in case of high speed, crush and wear out the track of the road unduly.

A contrivance designed to meet these difficulties and effect at once the greatest degree of economy in this part of railway service has been invented quite recently, of which the inventor says: "It is estimated that there are at present about 16,000 locomotives in this country alone that are troubled by their lack of adhesion, and the study I indulged in was how to make these machines effective without injuring the track. 'The tender of the locomotive of the standard size weighs, when loaded, about 24 tons, and I undertook to transfer a part of this weight to the driving wheels of the locomotive at the will of the engineer and in exact proportion to the work the engine is doing, and this is perfectly accomplished. The engineer, without leaving his seat, can load his driving wheels at pleasure. The most important part of it is, that when the heavy work is done he at once discontinues its use and the engine is left light again for the speedy part of its work."

"My contrivance was put on engine No. 111, of the Boston and Albany road. It was a powerful engine, but short of adhesion, and, as engineer Hodge says, generally used a box of sand in making a trip. It now runs with a full load, in all states of the weather, without the use of sand. It has now been running about two months, and is apparently gaining in favor every day."

**A LUMINOUS LIQUID.**—It is well known that certain metallic salts, especially if previously heated, when exposed to direct sunlight, to the electric or the magnesium light, and then brought into a dark place, give off a yellow or a bluish-white light. Especially the sulphurates of magnesium, strontium, and calcium possess this property in a greater or less degree. Balmien has recently patented a mixture which possesses this property in a remarkable extent. Thus, if the dial plates of watches are coated with this composition and then with a colorless varnish, the figures may be seen in the dark at some distance, if they have been previously exposed to diffused daylight. According to my experiments the organic compounds of these metals possess the same property, especially rosin oil lime soaps. If 100 parts of rosin oil are hoiled in a suitable pan with 30 parts of freshly slaked lime, raising the heat by degrees, the mass which is at first lumpy becomes tougher, and finally passes into a thin liquid. As soon as this stage is reached, say at 320° Fah., the entire surface of the liquid becomes luminous in the dark, which is still more intense at a greater heat. At 350° Fah. the bluish-white light is very strong in the dark. Objects dipped in the liquid remain luminous for some time.—*B. Hoffman in Chemiker Zeitung.*

## The Telephotograph.

An apparatus has been devised by Mr. Shollford Bidwell which he calls the "telephotograph," and which, though still crude, makes an important step forward towards a solution of the problem of transmitting images by electricity. The instrument is described in the *Iron Age* as follows: The positive pole of a battery is connected, through a set of adjustable resistance coils, to a platinum stylus which rests its marking point on a plate of zinc, covered with a sheet of paper moistened with a solution of iodine of potassium. The circuit of the battery is completed through a galvanometer by a wire from the zinc plate to the negative pole of the battery. This is the receiving part of the apparatus. The transmitter consists of a second battery, the negative pole of which is connected to the platinum stylus through a sensitive eelenium cell, the circuit being completed also through the zinc plate and the galvanometer. Now, if the selenium cell be exposed to a strong light, or, in other words, if a beam of light be focused on it, and the variable resistance be so adjusted that the opposing currents in the two battery circuits exactly neutralize each other, no current will flow from the stylus to the plate across the iodized paper, and hence no stain of liberated iodine will mark the paper if the stylus be drawn across it. But if the light be shaded off the selenium, the resistance of the latter will increase, and the current from the first battery will, therefore, predominate, so as to cause a flow of electricity down the stylus. When the stylus is drawn across the paper it leaves its trace as a brown mark of liberated iodine; and this trace is strong or faint, according as the current is strong or feeble—that is to say, in proportion as the light is less or more intense. The galvanometer serves to indicate when the balance of currents is exact; and the connecting wires which correspond to the telegraph line between the two stations, where the transmitter and receiver are placed, may of course be of any length. With an apparatus having substantially these elements, Mr. Bidwell, before the physical society, succeeded in transmitting simple designs.

**ARE THEY NOT ARTISTS?**—A correspondent of the *German Town Telegraph*, after alluding to the grand paintings, superior sculptures, etc., results of the genius of our highest artists, asks:

"Are there not others, also, whom we may call artists? When," continues the writer, "I stand among a lot of common stone masons and see one man walk around among the stones, picking one out here and there, dressing one here and there, just as though he were playing, and then suddenly begin to set them up as fast as he can handle them and the mortar, making a handsome wall, I call him an artist. If we look at a man hewing a leg straight and smooth, alike in thickness the whole length, and not leaving a mark of the juggling axe, he too seems to me to be entitled to the above name. Or a man, who cannot even write his name, bracing himself aside of a huge tree, and sending his axe into it with the precision of a rifle shot, making every stroke tell, and never missing the mark, and when cut in one side changes hands on the axe and cut the other, and throw the tree just where he wishes it to fall—he, too, is not devoid of artistic skill. And many a common blacksmith, who will forge out a piece of iron or steel as round as if it had passed through the turner's hands, or as square as if ran through the planing machine—I count him among the artists. Yet none of these men are ever classed with those of the higher arts."

**DANGER OF LIGHTNING FROM TELEPHONE CONNECTIONS.**—The Cantonal government of Zurich, having been applied to by a telephone company for permission to fix the supports of insulators on the tops of certain public buildings, applied to Prof. Kleiner for an opinion. The following is a summary of the chief points in his report: 1. The danger of lightning in houses over which telephone wires are stretched is not increased, but lessened, if the total conductivity of a wire is approximately equal to that of a lightning conductor. This condition is not always fulfilled under existing arrangements. It may be insured by very simple arrangements, such as the introduction of a special wire for the conduction of lightning wherever the number of wires of two millimeters in thickness running in the same direction is less than 60. This should be insisted upon in all cases. Single connections running along the houses should be stronger than at present—at least as strong as telegraph wires.

2. As the properties of a telephonic plexus for attracting and conducting lightning extend over far wider tracts than those of a lightning rod, a strict regulation of their make and condition is necessary.

The use of telephones should be suspended during thunderstorms.—*Neue Zurich Zeitung.*

**PULVERIZED COAL.**—The *Iron Age* says that Messrs. Alexander & Sons, of New York, are making some very successful experiments at the Washington Iron Works with pulverized coal. The coal is blown into a furnace and burns freely with a strong heat, but the apparatus is being altered to secure still better results, after which the process will be practically tested on one of the Havana steamers. The coal is fed from a perpendicular funnel, and the air enters horizontally from the side.

**MASTODON BONES.**—There were mastodon bones found recently in the La Grange gravel claim, by Joseph Jernigan, recently drowned in the Tuolumne river. At the time of the discovery the miners were washing with hydraulic pipe many ft. below the surface. The bones of this immense animal were lying down at full length. As soon as the air struck them, some of the finer bones decomposed; but at the present writing a number of the teeth and a tusk are in a good state of preservation. From the skeleton found, this animal must have been immense—one bone in particular is about 4 1/2 ft., while in the ordinary ox the corresponding bone is only about eight inches; the tusk is about 16 ft. long; one of the molars is about six inches across and the back grinder eight inches in length and four across.

camp. Much of the melting in the mountains, making every thing slushy. With such mines as the Bully Boy and Webster, the Fillmore, the Great Western, the Copper Belt and five other prospects undeveloped, in Ohio mining districts, then the Deer Trail, the Pluto, the Chrystal, Clyde, Homestate, with a great many more equally as good, but undeveloped, in Montana, and the great variety of the Deer Trail mine. Add to these the rich prospects on Ten Mile—such claims as the Rothschild, the Uncle Sam, the Mailfork and the Bully Boy—all within a radius of 10 miles, I think we have good and sufficient grounds to build hopes of a great mining center. With no excitement, we may have to wait some time for the camp to place itself before the mining towns. The best place to go to, if you do not own a good mine, is in the Green-Eyed Monster the owners have lived in sinking, drifting, crosscutting and tunneling. They have opened out a body of ore that shows, by actual measurement, 120,000 tons of fine milling ore, the average assay of which is \$25 per ton. The ore in this mine does contain scarcely a particle of refractory material. It is the best west, and about the best in the country, is a rich claim called the Pluto, owned by Johnny Campbell and Mr. Morton. This mine is the richest little vein in this country. The Occidental M. & Co. have commenced work and have already struck shipping ore, with plenty of 40 rock that would work here. The ore is free milling.

## Priority in Mining Surveys.

The Secretary of the Interior has recently established the following rule in regard to the survey of mining claims, viz: "The mining survey first applied for shall have priority of action in all its stages in the office of the Surveyor General, including the delivery thereof, over any other survey of the same ground or any portion thereof;" and authorized this office to prescribe regulations for the proper enforcement thereof.

Commissioner Williamson, of the General Land Office, has, in accordance with this ruling, issued instructions to Surveyors General as follows:

In the future, therefore, you will be governed by these regulations:

1. The Surveyor General should not order or authorize a survey of a claim which conflicts with one previously applied for until the survey first applied for has been completed, examined, approved and platted, and the plats delivered.

2. When the conflict does not appear until the field-notes of the respective surveys are returned, then the survey first applied for should be first examined, approved and platted, and the plats delivered before the field-notes of the survey last applied for are taken up for examination or plats constructed.

3. When the survey first authorized is not returned within a reasonable period, and the applicant for a conflicting survey makes affidavit that he believes (stating the reasons for his belief) that such first applicant has abandoned his purpose of having a survey made, or is deferring it for vexatious purposes, to-wit, to postpone the subsequent applicant, the Surveyor General shall give notice of such charges to such first applicant, and call upon him for an explanation under oath of the delay. He shall also require the Deputy Mineral Surveyor to make a full statement in writing, explanatory of the delay; and if the Surveyor General shall conclude that good and sufficient reasons for such delay do not exist, he shall authorize the applicant for the conflicting survey to proceed with the same; otherwise, the order of proceeding shall not be changed. The Surveyor General shall retain on his files all affidavits, etc., relating to the controversy, and in event of an appeal from his action shall forward the same to this office.

The Deputy Surveyors are under your control in the execution of their work, and you will properly instruct them concerning the prompt execution thereof.

4. Whenever an applicant for a survey shall have reason to suppose that a conflicting claimant will also apply for a survey for patent, he may give notice in writing to the Surveyor General, particularly describing such conflicting claim, and file a copy of the notice of location of such conflicting claim. In such case the Surveyor General will not order or authorize any survey of such conflicting claim until the survey first applied for has been examined, completed, approved, and platted, and the plats delivered.

It is the intent of the rules adopted as aforesaid to furnish the first applicant in good faith for a survey with the opportunity to first present his application for patent at the district land office, and thus secure orderly proceedings. When the field notes and plats have been delivered, however, it is held by the honorable Secretary that no authority exists to prescribe the order in which application for patent shall be filed, it being then the right of the party to present his application when he chooses.

Therefore you will seek to avoid errors in the matter of delivery of surveys, and in case of conflicting surveys will postpone the delivery of those last applied for for such temporary period as will be sufficient to enable the first applicant to present his application for patent.

When the survey first applied for is executed and delivered in ignorance of a conflict which speedily thereafter shall appear by the return of a subsequent survey, you will notify the prior party of the existence of a conflict. If, however, the first survey shall have been delivered for any considerable period, at the time the conflict is shown such notice need not be given.

**SALE IN ARIZONA.**—The Mammoth mine, which was located and formerly owned by J. H. Williams, has been recently sold to Eastern parties through the instrumentality of their representative, William E. Graves, for the sum of \$35,000. This property is situated on the west side of the Santa Rita mountains, and is within the boundaries of the Helvetia district. As no work has as yet been done, the mine was sold simply on its surface showings. The crops are simply enormous, being in places over 130 ft in height, and 210 ft in width. Mr. Graves states that there are at least \$2,000,000 worth of copper in sight, calculating from the assay returns made at various places along the vein, which prove that it will run easily 20% copper.

**Tybo.**—The following is an extract from a letter from Tybo district, to the Eureka Sentinel: The prediction I made in one of my letters a month past, when the Tybo Con. Mining Co. closed down, that the property would not remain idle over a month, has proved true, for to-day's mail gladdened the faces of many of our business men and our grass widows whose husbands have left them in search of work. These widows were told to send for their husbands and have them ready to go to work on the 1st of April.

## Petroleum and Plant Life.

At the last meeting of the California Academy of Sciences, a discussion took place on the subject of the use of petroleum for destroying scale insects on rose bushes. Dr. Henry Gibbons said that two months ago he put petroleum on the trees in his garden. Since then the trees have grown better than ever before; they have grown faster than ever before, and given better roses than ever before. The petroleum seems to kill the scale insect. The handsomest rose he exhibited was from a bush which looked nearly dead a short time since. The petroleum was mixed with castor oil. It is not applied profusely and allowed to run down the roots. Perhaps in a crude state the petroleum would be bad, even on the stalks; but mixed with the castor oil it appears to be advantageous to the plant. The compound does not evaporate nor give out the insoluble portion. Therefore you have a permanent coating, acting on the entire surface of the plant.

Dr. Gibbons exhibited a large bunch of beautiful roses of exceeding fragrance, and in full bloom, which he gathered from a bush in his garden which two months ago was overrun with scale bugs and nearly dead.

Now, since using the petroleum and the castor oil, no sign of any scale insect can be seen in the whole garden. He thought castor oil was the only oil that will mix with alcohol, turpentine and the benzines. It is soluble in alcohol, and when mixed with crude petroleum forms a sort of varnish or cement, which remains on the bushes, and does not fall to the ground. Petroleum, uncombined with castor oil, evaporates swiftly, but when combined forms a useful coating to preserve the plant. Many things have been thus tried. Trees have been whitewashed with caustic potash and lime. One of his rose bushes, nearly ruined by scale insects, thus treated, has borne an unusual number of roses, and a single cactus has borne 200 flowers this season. He thought these were practical facts, and quite as valuable as theoretical ones, although he valued both, and was glad to learn of any experience having a bearing of such importance to the agricultural industries of the human family. He cautioned persons against saturating the earth with petroleum as such a course prevents future vegetation. Like all things else, its moderate use, wisely directed, is good, and its excessive use is destructive. A grain of opium relieves pain, but its habitual use persisted in, brings death.

Dr. Behr said that as the mixture was not soluble in water, if it reaches the earth, it cakes the ground and thus shuts out the air, which must permeate the surface and is necessary to plant growth. A few applications will make rose-bushes grow better if sparingly applied, and kill the scale-bugs, but if allowed to reach the soil, it renders vegetation thereafter impossible in that spot, until it is eradicated.

Dr. A. Kellogg thought a simple wash of common lye would at first be sufficient in many cases. Petroleum deteriorates ground for crops. One scale-bug has 60 offspring.

Mr. Verder received a large lot of lemon trees from Australia, covered with scale bugs. He applied refined petroleum to the leaves carefully, and they all fell off, but every bud died, and fresh leaves came out, and the plants continued healthy for many years. He afterward applied it successfully to orange trees. He thinks there is a misapprehension among those who condemn its use. It should not be allowed to reach the ground.

**LONGITUDE OF THE ASIATIC COAST OF THE PACIFIC.**—It is understood that Lieutenant Commanders F. M. Green and C. H. Davis, Lieutenants S. M. Ackley and John Morris, and Surgeon Dale, U. S. N., now in San Francisco, have been detailed by the Navy Department to determine the correct longitude of the Asiatic coast of the Pacific ocean. They sail Saturday for China, to join the *Palos* on the Asiatic station. All points on the coast of Japan and China, connected by cable, will be visited, and their exact longitude determined. The American officers have permission from the cable companies to establish stations and use the wires at night. English officers are engaged in a similar work in New Zealand and Australia. The information obtained from the observations will be exchanged by the two nations. English officers have determined the longitude as far as Madras and Russian officers have made observations on the Siberian coast. All observations have been taken from the Hongkong observatory. The American party will ascertain the precise longitude of that place, there being a question as to the accuracy of the standard. The object of this movement by the Navy Department is to establish correct standards, from which true charts for the protection of maritime interests may be produced.

**IMITATION INLAYING.**—Suppose an oak panel with a design inlaid with walnut is wanted. Grain the panel wholly in oil. This is not a bad ground for walnut. When the oak is dry, grain the whole of the panel in distemper. Have a paper with the design drawn thereon, the back of which has been rubbed with whitening, place it on the panel, and with a painted stick trace the design. Then with a brush and quick varnish trace the whole of the design. When the varnish is dry, with a sponge and water remove the distemper where the varnish has not touched. This, if well executed, presents a most beautiful imitation of inlaid wood. Marbles are executed in a similar manner.

## South American Mines.

*The Miner*, published at Barbacoas, in the Republic of the United States of Colombia, South America, shows up the advantages of that country as a mining section. The mines in that section, called the Barbacoas mines, have been worked for hundreds of years by the old and slow process only known to the inhabitants of that country, and consequently not one-tenth of the ground rich with gold has been worked over.

Notwithstanding the long time the mines have been worked not a tithe of the ground producing gold has been worked over. As a general thing that part of the mine where water could be most easily obtained and which could be worked at the least expense to the owners has been worked. Immense tracts yet remain untouched on most of the mines, especially so between the rivers Telemhi and Magni. Besides, the streams forming the head waters of these and other rivers are almost unknown to the miner, and are not even prospected except very superficially, but gold is known to exist in all of them. If these unworked grounds of the old mines, and the idle government lands of the head waters of the rivers were only in the hands of energetic and experienced California miners, with the improvements in the ways of working which they would bring with them, the world would be surprised at the result. California in its palmist days would be repeated. The great need of the country to produce this result is an emigration of miners of experience, with improved machinery, such as California produces and Californians know how to use—men of small capital and energy, not afraid of making improvements in the cutting of ditches, building of reservoirs or other means according to the wants of each locality, in bringing on water to the mines, or in draining grounds known to be rich in gold.

With the object in view of letting the world know of the richness in mines, as to give information of new arrangements made here for the reception of emigrants, an association has been formed in this place, of the best and most active part of the inhabitants, together with mine owners, who bind themselves to give better advantages than heretofore to miners coming here to open up the immense resources of this most neglected part of the world.

## Nevada City District.

While the newspapers of the country are teeming with exaggerated reports of the mineral discoveries being made in other sections of the country, this district is pursuing the even tenor of its healthful way and rapidly proving itself to be among the best fields in the world for legitimate mining operations. The quarter of a century's experience in quartz mining here has taught our claim owners many a valuable lesson about the industry, including every detail from the time the grass roots are cut till hars of gold are ready for shipment. There is no teacher like experience; and the experience that will enable a man to conduct a mine successfully in one section is often found valueless when he applies its principles in another locality. It is only within the last two or three years that the miners of Nevada county have begun to approach a thorough understanding of their business. The saying of this is no disrespect to earlier workers, for it was due to their intelligent efforts and valuable discoveries made from time to time that the industry is now so nearly reaching perfection. It has been said "there is nothing new under the sun," but the utterance was made before men began to search in the bowels of the earth of the State of California for metallic treasures. There has been a remarkable reformation in our midst, and it must be remembered that our miners are not imitators, but originators of ideas. They have studied out more certain and economical ways to find gold-bearing ledges than they were wont to pursue until now; they have disproven the once universally accepted theory that their mines would not pay beyond a certain depth, and found that the most valuable deposits often lie a thousand ft. or more below the starting point; they are learning simple and economic methods by which to master the most rebellious and low-grade ores when necessary, besides many other things. They are not too indolent to think, or too cautious to experiment to a reasonable extent. They are building up what we sincerely believe will within the next three or four years be the leading gold mining center of America. During no three past years combined has so much advancement been made in the way of adding hoisting and milling facilities as is the case this season. —*Nevada Transcript*.

**UNITED STATES AID TO AGRICULTURE.**—According to the latest advices from Washington, the total amount appropriated for the Agricultural Department is \$330,050. Among the special items is an addition of \$500 to the salary of the Commissioner (a restoration to \$3,500); examination of and report on wool, \$5,000; for investigation of animal diseases, \$25,000; experiments on tea, \$5,000; insect investigations, \$10,000; for continuance of experiments in sorghum sugar, \$17,000; beet sugar, \$10,000; for a building on the department grounds for the display of agricultural implements, \$10,000.

The whole distance from New York to San Francisco by the new southern route is more than 300 miles longer than by the northern route, but the southern route has better grades.

## Marine Glues.

At a recent meeting of the Polytechnic Club of the American Institute a paper was read on "Glass and Cements," by Dr. John Phin. In the course of his remarks he had the following to say about marine glues.

Waterproof glues are made in two ways. Glue and linseed oil are recommended, but have had better success with the mixture. The chromates may be used with glue. These, when exposed to the light, render the compound insoluble.

Aquarium cement is the best waterproof cement I know. The formula is: Litharge, 3; white sand, 3; plaster of Paris, 3; rosin, 1; hoiled linseed oil, —.

The solids are to be taken by measure in powder and mixed. As it sets rapidly, the same must not be added until it is wanted for use. It is better for being put into a mortar and pounded. It hardens in three days. It will hold glass firmly, and with it glass tanks may be made without frames, if the angles are well filled with cement. It is a kind of mastic, and could be used on brick.

What is technically known as marine glue stands almost by itself. Where it can be put on hot it is admirable. It is composed of India rubber and shellac, dissolved in naphtha. Some kinds are hard, some almost liquid. I have seen this glue adhere to glass so firmly as to tear the glass when plates were separated.

In the discussion which followed, Dr. Parmalee gave some interesting experiences in the manufacture of marine glue. He said its melting point was about 230 degrees, and in making it was injured if the heat was carried above this point. In applying it care should be taken not to go above this heat, as the melting point would be raised and the strength diminished. In applying it the soldering iron may be used, but its heat must be regulated.

In answer to Dr. Parmalee, Dr. Phin said that Jeffries, the inventor, put three kinds of marine glue in the market; that the kind he himself had used was that known as "D. H. K.," and he had no difficulty in making it adhere to glass—a point which caused some surprise.

## Chair of Entomology at the University.

The Board of Regents of the State University have promptly granted the request of the fruit growers as expressed by their several societies, and have created a chair of entomology, provided the State will increase the appropriations to the University sufficiently to cover the cost of the new professor. This we trust will be done speedily, for the successful working of the anti-insect acts demands the services of a good economic entomologist who is abreast of the progress made in the anti-insect warfare during the last few years.

At a meeting of the Regents held April 12th, the following report of Committee on Instruction and Visitation was received and adopted:

The committee of instruction and visitation have had under consideration the petitions of the several societies and citizens asking for the creation of a Chair of Entomology, and would respectfully report that they have carefully considered the subject and would recommend:

First.—That a Chair of Entomology, adjunct to the Chair of Natural History, be created.

Second.—This recommendation is based and conditioned upon the premises that the legislature will annually appropriate not less than \$2,000 for this especial purpose.

**IMPORTANT TUNNEL ENTERPRISE.**—The *Placer Herald* says: Auburn is now growing, and is now prosperous, and a new project is on foot with every assurance of success, which is calculated to add to that growth and that prosperity. We refer to the proposed cross tunnel in Duncan hill. In this hill there are from a dozen to 15 quartz ledges that rib the hill from east to west, and every one of them, so far as is protected, are rich above the average. The cross tunnel running from the south side will cut these ledges at a depth of from 800 to 900 ft. on the incline, affording drainage to all and a very convenient means of working them. With this tunnel completed, even though the royalty for using the tunnel should amount to \$2 or \$3 per ton, the inducement for the different claim owners to go to work taking out ore would be irresistible. They have already commenced work. The place for the opening of the tunnel is being faced.

**A NEW PRODUCT FROM BIRCH BARK.**—A French inventor has patented a method of improving india-rubber and gutta percha by the addition of a distillate of birch bark. By distilling the outer layers of the bark he obtains a dense black gummy matter which possesses the properties of ordinary gutta percha with the additional quality of resisting both the action of air and the strongest corrosive acids. He claims also that by adding a small portion of the birch bark gum to gutta percha or india-rubber (one-twentieth part will suffice), the durability of the rubber or the gutta percha will be greatly increased, the new mixture not being acted upon by the air or by acids.

**COOLING HOT JOURNALS.**—A simple method of cooling shaft journals consist in placing an endless belt of a loose water-absorbing texture on the shaft as near the heated part as may be and allowing the lower light to run in cold water, which may be held in a vessel at a convenient distance below the shaft. Continuous contact of the liquid band carries away the heat of friction as it is produced, without spilling or splashing of water on and about the machinery, and without contact of the lubricant in the journal boxes.

## General Mining Notes.

MANY prospectors are leaving the Comstock for the Wood River country.

SILVER bars to the value of \$800 were shipped from the Owen's Lake mine, Inyo, the other day.

THE bullion yield of Tombstone and Harshaw districts, Arizona, for the first quarter of 1881 was \$992,337 16.

FROM January 1st to March 20th the Ontario mine produced \$502,593. The shaft is now down to the 800 ft. level.

THE Grand Central M. Co.'s mill of Tombstone is crushing 90 tons ore daily. It has 30 stamps, and is pronounced to be very complete.

THE new gold mine, situated opposite Bishop creek, in the foothills of the Inyo range, has been sold by Hypolite Calcon and partners to Bodie parties for the sum of \$15,000 cash.

THE result of the semi-monthly clean-up at the Homestake mine for March 15th was four gold bricks, one of which weighed 2,500 oz., the largest ever made at that point, valued at \$45,000.

DURING the year 1880, 16 new stamp-mills were erected in Dakota. The present year the Homestake intend adding 400 stamps. At present there are nearly 1,700 stamps in the Black Hills.

A STRIKE of sufficient importance has been made in the San Jose mine, at Pagan canyon, to justify starting the old Steptoe and Social mill again, which, we learn, will be done without delay.

OLD Comstock brokers have opened offices in Tombstone, Arizona, in order that the people of that district may have the opportunity of dealing in Comstock shares. This seems rather strange.

IN Cherry Creek district, Nevada, are over 200 miners, and there are excellent indications of permanency in the mines. There is a regular porphyry belt four or five miles long, lying on slate and lime.

IN Flowery district several mills are running on old croppings of the Lady Bryan, Monte Christo and several other veins, the plan of deep shafts and extensive hoisting works having been abandoned for the present.

THE Tombstone M. and M. Co. of Arizona paid a dividend of 10 cents per share, or \$50,000, at the office in Philadelphia, on the 15th. This is the 13th consecutive monthly dividend, aggregating \$650,000.

A Herald Prescott, A. T., special says: Shoane, known as "old Tex," a peculiar character familiarly known in the mining districts, was murdered on the trail leading from his ranch to Tip-top. He was found Sunday with two bullet holes through the body.

THE Black Rock quartz mine, a few miles southwest of Greenwood, El Dorado county, has gone into the hands of a Philadelphia company, who are preparing to start it up this spring. The Cedarburg mine, north of Greenwood, has also changed hands, and will at once be provided with hoisting works.

THOS. D. SARGENT, writing to the London Mining Journal, expresses the opinion that in most instances the stamps used on auriferous quartz are altogether too heavy; so heavy that much of the gold is beaten out into lamina so thin that they are floated away by the water, which is also used to excess.

THE New York Commercial Bulletin has the following among its railroad items: A dispatch from Albuquerque, of April 9th, from F. W. Smith, Superintendent of the Atlantic & Pacific railroad says: "Something should be done at once to develop the coal, which we have in large quantities. Parties are urgent to take it out. The sixth section of this railroad will be ready next week."

THE Southern California and Arizona Mining Bureau has been organized with headquarters at Riverside. The bureau will examine and report upon mines, make assays, and negotiate for the sale of mining property in southern California and Arizona. Following are the officers: General Manager, Dr. K. D. Shugart; Secretary, H. J. Rudisill; Treasurer, A. S. White; Superintendent, Prof. G. E. Bailey, M. E., formerly Professor of Analytical Chemistry in the University of Nebraska.

TAYLOR DISTRICT.—The Ward Reflex says the Monitor mine in Taylor promises to be the coming bonanza of that district. A vein of \$300-ore, four ft. wide, is now exposed. Taking in the second class-ore the vein is between 5 and 10 ft. wide. The vein which from the first laid flat has commenced to pitch into the mountain. Messrs. McGill, Briggs & Lyons, the owners, are familiarly known over that way as the Bonanza Kings of Taylor. We can stand a bonanza king or two in White Pine.

A NUMBER of our chloriders, says the Pioche Record, have their ore on the dumps ready to ship to Bullionville at a moment's notice. All the cars have been loaded and run on the side track, where they have remained for over a week, and the chloriders' patience is worn out. There is considerable more chloriders' ore in Pioche than a person has any idea of. Johnny Deek & Co. having at least a train load of ore. The men working in the Meadow Valley mine have large quantities of ore stored away in the drifts, and we learn that hoisting will commence in a day or two.

## USEFUL INFORMATION.

## Belmontyle Oil—What Is It?

It is an oil that prevents rust, tarnish or verdigris, without injuring the brightness of the polished metal. In short, it is a preventative of the oxidation of metals, and is, therefore, useful in preserving bright work on steam engines when not in daily use; for firearms, sewing machines, safes, saws, tools, skates, cutlery, etc. The oil is of a very greasy, slippery and filaceous nature; its odor is similar to that of mineral oils. When exposed to the air in open vessels a long time it will lose its slippery, filaceous nature, but not its preventative power against rust. Nevertheless, the keeping of the oil in well corked up tin or glass bottles is always recommended. It will draw into porous wood very briskly, deprive the same of its hygroscopic peculiarity and protect it against rot-tenness. Rust is by this oil sooner dissolved than by any other; mixed with water it will get a milky appearance and undergo a decomposition. With spirits of hartshorn it will form a clear fluid liniment. Very thin coats of this oil on metal will evaporate after a while, and leave a very thin lamella protecting the metal. This lamella when spread over with Belmontyle oil will be dissolved again.

Rooms where this oil is used, will be kept free of moths and other insects. It appears transparent, with a slight yellowish wine color, in small white bottles and not over half an inch in diameter; when the diameter is larger it is somewhat reddish. Its specific gravity is between .875—.890. A higher specific gravity infers adulteration; at 41° F. it becomes dim; at 37° F. crystals will appear in it; at 21° F. it becomes still and chilled; but by trituration will be changed into a thin fluid liniment, and at 43° F. its former clear transparent nature will be restored without leaving a sediment.

In reference to its application to steel and iron, we may say that a thin coat of the Belmontyle oil forms a very thin, dry and invisible lamella, preventing the metal from coming in contact with the air and moisture without diminishing its brightness. It can be easily removed by a second application of the oil, or by benzine. This article is therefore especially adapted for use on bright metal which needs protection from rust during storage or transportation, and in preserving parts of machinery, etc., while in course of fabrication. It also makes blined and browned work brighter, and hold the polish.

The oil proves efficacious in preventing rust on bright surfaces of machinery or goods that have to be transported by sea. Bright brass or copper work oiled with it will also retain its original color and brightness. When used on bronze the formation of verdigris will be entirely prevented, whether the metal be exposed to the weather or not, and the color remain unchanged. The cleaning properties of the oil are superior. It will remove gum, etc., immediately, and rust after the lapse of 24 hours; very rarely a second greasing will be found necessary.—*Boston Journal of Commerce.*

WORKMEN'S PANTALOONS often become too filthy to wear, on account of being saturated with oil and grease, long before they are really worn out. The following method of washing such articles of clothing, so as not to discharge the color, is recommended. It is impossible to wholly prevent fading, but if not left in the water too long the washing out of the dye will not be very great: Water 1 gallon, soap  $\frac{1}{2}$  lb.; boil to dissolve; add 2 oz. borax; dilute with about 8 gallons water; work the goods through as quickly as possible and rinse without ringing. An aqueous solution of 1 part copperas and 7 parts logwood extract may be used for reviving the faded color of cheap black goods.

HYBRIDIZED COTTON.—Experiments have developed a crop of hybridized cotton, which has been raised for several seasons, and which is worm-proof. The worms, a great hindrance to the cultivation of the ordinary plant, have never troubled the weed or foliage. It is claimed that the ordinary cotton plant has been hybridized with a certain weed, (the name of which and the process is a secret), and that when the cotton plant worm is placed upon this hybridize, it turns away in disgust, and absolutely refuses to remain or feed upon it. If there is truth in this reported discovery, it is a very important one.

NAIIS.—What are technically known as nails range from one and one-third to six inches in length, and from 800 down to 10 nails to a pound. But the genus extends upward, under the special name of spikes to two ft. or more in length, a single one of which will weigh from six to 15 lbs., and downward, under the name of brads, to one-quarter of an inch in length, and to 10,000 to a pound.

INDIA INK IN DRAWING.—Much trouble is experienced in the use of india ink from the fact of its drying so rapidly on the porcelain on which it is used. This trouble may be avoided by adding a few drops of glycerine to the ink.

ADHESIVE FOR BELTS.—A writer says a good adhesive for leather belts is printers' ink. "I have the case of a six-inch belt running dry and smooth and slipping, which latter was entirely prevented for a year by one application of printers' ink."

COLOR AND HEAT.—The following experiment was performed by Franklin to ascertain the absorption of light and heat by various colors. He took a number of little square pieces of cloth of various colors—black, deep blue, lighter blue, green, purple, red, yellow and white, and laid them down on the snow on a bright, sunshiny morning. In a short time the black, being most warmed by the snow, was sunk so low as to be almost below the stroke of the sun's rays; the dark blue almost as low; the lighter blue not so low as the dark; the other colors less as they were lighter, and the white remained on the surface of the snow. We thus learn that black cloths are not so fit to wear in a hot sunny climate as white ones.

MAKING HOLES IN GLASS AND PORCELAIN.—The operation of making holes and sections in glass and porcelain is often a troublesome and unsatisfactory one. The firm of Richter & Co., in Chemnitz, have found a way of so impregnating thin German silver disks (.59 to .98 inch diameter) with diamond, that when fitted to a quickly rotating tool, these cut through glass or porcelain in a few seconds, or effect any desired carving with great accuracy. With cylinders made on the same principle, round holes can be quickly and exactly made. The wear of the implement, even after much use, is hardly perceptible.

CEMENTING LABELS TO METAL.—For attaching labels to tin and other bright metallic surfaces, first rub the surface with a mixture of muriatic acid and alcohol; then apply the label with a very thin coating of the paste and it will adhere almost as well as on glass.

TO REMOVE OLD PAINT.—Slack three lbs. of stone quicklime in water, and add one lb. American pearlsh, making the whole into the consistency of paint. Lay over the old work with a brush, and let it remain from 12 to 14 hours, when the paint is easily scraped off.

## GOOD HEALTH.

## What Air Shall We Breathe at Night?

Many years ago Florence Nightingale assaulted the popular superstition against breathing night air with the unanswerable question, "What other air can you breathe at night?" Dr. Oswald in a late number of the *Popular Science Monthly*, enters upon the assault against this superstition, which survives every attack, upon no other ascertainable ground than that the less reason there is for a superstition the harder it is to kill it.

"Before we can hope," he says, "to get rid of the consumption with any chance of success, we have to get rid of the night air superstition. It is probably the most prolific single cause of impaired health, even among the civilized nations of our enlightened age, though its absurdity rivals the grossest delusions of the witchcraft era. The subjection of holy reason to hearsays could hardly go further.

"Beware of the night-wind; be sure and close your windows after dark!" In other words, beware of God's free air; be sure and infect your lungs with the stagnant, azotized and offensive atmosphere of your bed-room. In other words, beware of the rock spring; stick to sewerage. Is night-air injurious? Is there a single tenable pretext for such an idea? Since the day of creation that air has been breathed with impunity by millions of different animals—tender, delicate creatures, some of them—fawns, lambs and young birds. The moist night air of the tropical forests is breathed with impunity by our next relatives, the anthropoid apes—the same apes that soon perish with consumption in the close though generally well-warmed atmosphere of our northern menageries. Thousands of soldiers, hunters and lumbermen sleep every night in tents and open sheds without the least injurious consequences, men in the last stage of consumption have recovered by adopting a semi-savage mode of life, and camping out doors in all but the stormiest nights. Is it the draught you fear, or the contrast of temperature? Blacksmiths and railroad conductors seem to thrive under such influences. Draught? Have you never seen boys skating in the teeth of a snow storm at the rate of fifteen miles an hour? 'They counteract the effect of the cold air by vigorous exercise.' Is there no other way of keeping warm? Does the north wind damage the fine lady sitting motionless in her sleigh, or the pilot and helmsman of a storm tossed vessel? It cannot be the inclemency of the open air, for, even in sweltering summer nights, the sweet south wind, blessed by all creatures that draw the breath of life, brings no relief to the victim of aerophobia. There is no doubt that families who have freed themselves from the curse of that superstition can live out and healthier in the heart of a great city than its slaves on the airiest highland of the southern Apennines."

Is there not, the reader perhaps asks, danger in the malarious air of the Roman campagna or the Charleston meadows? Yes! There are regions where the air is poisonous. But the only way to escape the poison is not to live in such a region. You might as well allow sewer gas in your bath-room and expect to escape the poison by keeping the chamber door closed, as to live in a malarious swamp and escape the malaria by trying to live in an air-tight house. Any fresh air is better than any stale air.—*Ec.*

## Milk in Fevers.

EDITORS PRESS:—I have just read Mr. I. B. Rumford's advice in the *RURAL PRESS*, on diet in malarial regions; can agree with him as to using swine flesh. I prefer to do without meat when fresh mutton or beef is not to be had. But I am surprised that he includes milk and butter among the objectionable articles of diet, as my experience has led me to believe good milk beneficial in case of fevers, for I have been greatly benefited by its use whenever we have been fortunate enough to get a supply.

P. LOUCKS.

King's River, Cal.

RAW OYSTERS.—Dr. William Roberts, in an interesting series of lectures on digestive ferments, published in the *Lancet*, says: The practice of cooking is not equally necessary in regard to all articles of food. There are important differences in this respect, and it is interesting to note how correctly the experience of mankind has guided them in this matter. The articles of food which we still use in the uncooked state are comparatively few, and it is not difficult in each case to indicate the reason of the exemption. Fruits, which we consume largely in the raw state, owe their dietetic value chiefly to the sugar which they contain; but sugar is not altered by cooking. Milk is consumed by us both cooked and uncooked, indifferently, and experiment justifies this indifference; for I have found on trial that the digestion of milk by pancreatic extract was not appreciably hastened by previously boiling the milk. Our practice in regard to the oyster is quite exceptional, and furnishes a striking example of the general correctness of the popular judgment on dietetic questions. The oyster is almost the only animal substance which we eat habitually, and by preference, in the raw or uncooked state, and it is interesting to know that there is a sound physiological reason at the bottom of this preference. The fawn-colored mass that constitutes the dainty part of the oyster is its liver, and this is little else than a heap of glycogen. Associated with the glycogen, but withheld from actual contact with it during life, is its appropriate digestive ferment—the hepatic diastase. The mere crushing of the dainty between the teeth brings these two bodies together, and the glycogen is at once digested, without other help, by its own diastase. The oyster in the uncooked state, or merely warmed, is, in fact, self-digestive. But the advantage of this provision is wholly lost by cooking, for the heat employed immediately destroys the associated ferment, and a cooked oyster has to be digested, like other food by the eater's own digestive powers.—*Scientific American.*

MEDICAL USES OF FIGS.—Prof. Bouchut mentions some experiments he has made, going to show that the milky juice of the fig tree possesses a digestive power. He also observed that when some of this preparation was mixed with animal tissue, it preserved it from decay for a long time. The *Medical Press* refers to this fact, in connection with Prof. Billroth's case of cancer of the breast, which was so excessively foul smelling that all his deodorizers failed, but on applying a poultice made of dried figs cooked in milk, the previously unbearable odor was entirely done away with. Certainly the remedy is worth trying.

THE smokers are clamorous for "smoking cars" on the elevated roads of New York. It is encouraging to note a vigorous protest against the proposition in the editorial columns of the *Evening Post*, which says: "This demand the directors should peremptorily refuse to grant." It also declares that "habitual smoking at all times and in all places is already carried too far, and there is no good reason for encouraging still further a practice which injures many persons beside those who inordinately indulge in it." To all of which every well wisher of the race should say heartily, "Amen."

SUCH IS THE POWER OF HEALTH that, without its co-operation, every other comfort is torpid and lifeless as the power of vegetation without the sun. And yet this bliss is commonly thrown away in thoughtless negligence or in foolish experiments on our own strength; we let it perish without remembering its value, or waste it to show how much we have to spare; it is sometimes given up to the management of levity and chance, and sometimes sold for the applause of jollity and looseness.

In business, in home life, in social intercourse, in politics, there is a success worth striving for, which is the attainment of the immediate object in view; but there is something much higher, far more valuable, far nobler. It is the purity of character, the elevation of the purpose, the fidelity to principle, and perseverance of effort which are of themselves the real success of life, and shine through all the clouds of temporary failures.

THE EFFECTS OF GREEN WRISTLETS.—The Bridgeport (Conn.) *Standard* says that a gentleman in that city has discovered, after suffering for weeks from what the doctors called an eruption, that the trouble was caused by wearing a pair of green woolen wristlets. He visited several physicians before the cause of his trouble was known. The dye-stuff was analyzed and found to contain poison enough to kill several persons if taken internally.

Our latest forms go to press Thursday evening

SAN FRANCISCO:

Saturday Morning, April 23, 1881

#### TABLE OF CONTENTS.

GENERAL EDITORIALS.—Wood River, 253-264. Passing Events; State Miner's Hospital; The Mining Bureau; A Prize for Scientific Research and Invention; Damages from Mining Operations, 264. The Pelton Water Wheel; Advertising Mining Companies, 265. Notices of Recent Patents; Patents and Inventions, 268.

ILLUSTRATIONS.—Map of the Lower Wood Country, 255. The Pelton Water Wheel, 261.

CORRESPONDENCE.—Tintic District, Utah; Pinaric Mining District, San Diego County; Copper Smelting—Its History and Processes.—No. 2, 258.

MECHANICAL PROGRESS.—Hand Skill and Machine Work; A New Self-Blowing Forge; Re-Rolling Rails; something for Inventors to Experiment With, 259.

SCIENTIFIC PROGRESS.—A Gigantic Artificial Moon; A Luminous Liquid; The Telegraph; Are They Not Artists? Danger of Lightning from Telephone Connections, 259.

MINING STOCK MARKET.—Sales at the San Francisco Stock Boards, Notices of Assessments, Meetings and Dividends, 260.

MINING SUMMARY from the various counties of California, Arizona, Montana, Nevada, Oregon, Utah, Colorado, and Idaho, 260-61.

MISCELLANEOUS.—Priority in Mining Surveys; Petroleum and Plant Life; South American Mines; Nevada City District; Marine Glues; Chair of Entomology at the University; General Mining Notes, 262.

USEFUL INFORMATION.—Belmonte Oil—What Is It? Hybridized Cotton; Nails; India Ink in Drawing; Color and Heat; Making Holes in Glass and Porcelain, 263.

GOOD HEALTH.—What Air Shall We Breathe at Night? Milk in Pivers; Raw Oysters; Medical Uses of Figs, 263.

NEWS IN BRIEF, on page 268 and other pages.

#### Business Announcements.

Lubricating Oils—A. C. Dietz & Co., S. F.  
Machinery—San Francisco Tool Company.  
Leather Belting and Hose—H. N. Cock, S. F.  
Assayer and Chemist—A. B. S. F.  
Searce Books—Paris Book Co., Chicago, Ill.

#### Passing Events.

The Legislature is in session at Sacramento, and has so far distinguished itself by cutting out the item of \$6,000 a year for two years for the State Mining Bureau. As that was the only thing before it relating to mining matters, it has not done much to foster the mining interest.

The weak hinge good cheer to us from all parts of the coast. Dispatches to the Associated Press from various points show that all through the interior a busy and prosperous summer is expected. People have begun to think owing to dull times past that California would continue to have dull times. This is by no means the case, however. The interior of the State through its producing forces is moving ahead vigorously. Mines are being opened in old camps as well as in new ones, and prospecting is going on in all directions. Now that spring has fairly opened an army of prospectors will soon be going the hillside in hopeful search of precious metals.

The most noticeable feature in mining circles at present, outside of the brisk stock market, is the Wood River excitement, which is causing many miners to leave this and neighboring States for that region. We have this week devoted considerable space to a map and description of the Wood River country, which will be found of use and value to any who are going to join the "rush." One thing this will do is to reduce the number of idle miners in some of the old camps of the coast.

The PRESS this week contains a very large amount of interesting and valuable matter for miners, which we hope they will appreciate. We are endeavoring to keep the PRESS up to a standard which will ensure its continued leadership of mining periodicals.

SENATOR FAIR has returned to this city. The length of his stay or his reason for coming are matters upon which the Senator is not to be interviewed. He is at the Palace.

#### State Miner's Hospital and Asylum.

The Governor has nominated and the legislature has confirmed the following trustees of the State miner's hospital and asylum: Solomon Heydenfeldt, Sr., George Hearst, B. B. Redding, of San Francisco; John Daggett, of Siskiyou, and Edward Coleman, of Nevada county. The first two mentioned, are for two years, the others for the four-year term. These trustees have general charge of the institution, appoint the superintendent, receive all real and personal property, etc. These trustees receive no compensation, and no appropriation is made by the State for building or maintaining the hospital, the whole thing coming from voluntary contributions. The town of Shasta has offered 200 acres of land in case the hospital is erected in that vicinity. It is hoped that other places beside Shasta will bid for the location. The State Treasurer will probably be appointed custodian for contributions, so no one need delay contributing on the plea that there is no one to receive the money. Mr. Daggett is a practical miner, at the head of the Black Bear and other Siskiyou mines. Mr. Coleman is one of the owners of the famous Idaho mine. All the others have been, or are identified with the mining interests of the coast.

The bill which establishes this hospital was drawn up by Mr. Joseph Wasson, of Mono county. It furnishes a framework or machinery whereby those who wish to contribute or bequeath to such an institution can do so. There was, up to that time, no laws permitting the State to accept donations for any purpose. This will now test the liberality, not to say gratitude and justice on their part, of that large class known as miners, by profession, even, exclusive of the class who have made their fortunes out of the mining interests of this coast, especially in this State and Nevada.

Were the common miners of California to-day alone to contribute the sum of one dollar, or even a "short bit," so to speak, the State Hospital proposed would, in a year or two at farthest, be an established fact.

There is scarcely a day in the year that the telegraph does not announce the death or crippling, disabling, etc., of from one to five men engaged in this perilous but most fascinating pursuit; especially is the danger incident to vein or deep mining more subject, tenfold, to accidents to limb and life than that of seafaring.

Vein mining is but in its infancy in California, the State having given birth to half a dozen other prosperous States and Territories, and on that score must still have a greater future than has been her past. It is rich in every mineral that enters into the arts and manufactures, outside of gold and silver, which metals are but partially developed.

Mr. Wasson, having originated the idea of the hospital, it remains for miners and friends of the mining to originate the hospital itself. The thing is nothing which the politicians are apt to get hold of, and the mining community, who are to be directly benefited, should contribute what it can in the good cause. We would like to see the hall set rolling by a good big lift from some one who has made his fortune out of the mines. But that need not keep back smaller sums. The beginning of the work has been made by the appointment of the trustees. The beginning of the contributions is still more important.

#### A Prize for Scientific Research and Invention.

The Royal Academy of Sciences of Turin, in accordance with the last will and testament of Dr. Cesare Bressa, and in conformity with the programme published in 1876, has announced that the term for competition for scientific works and discoveries made in the four previous years, 1877-80, to which only Italian authors and inventors were entitled, was closed on December 31st, 1880.

The academy has now sent notice to the California Academy of Sciences, and to other societies, that a new term for competition for the Bressa prize has begun, to which, according to the testator's will, scientific men and inventors of all nations will be admitted. The prize amounts to 12,000 Italian lire, or about \$2,340, so it is well worth contending for.

The prize will therefore be given to the scientific author or inventor, whatever be his nationality, who during the years included from 1879 to 1882, shall have, according to the judgment of the Royal Academy of Sciences of Turin, made the most important and useful discovery, or published the most valuable work on physical and experimental science, natural history, mathematics, chemistry, physiology and pathology, as well as geology, history, geography and statistics.

The term will close December, 1882. The prize will in no case be given to any of the national inventors of the Academy of Turin, resident or non-resident. The President of the Royal Academy of Turin is E. Ricotti. The Secretary of the class of physical and mathematical sciences is Ascanio Sobrero. The Secretary of the class of moral, historical and philological sciences is Gaspare Gorresio.

The product of the Star mine for March was \$26,969, which netted \$22,664.

#### The Mining Bureau.

Although the Assembly agreed to the \$6,000 a year for two years for the State Mining Bureau, the Senate rejected the item from the appropriation bill, after all Mr. Wasson's efforts to get it there. This action was in consequence of objection raised to the legality of the appropriation. The Bureau will therefore have to be managed on the funds coming from the tax or transfer of mining stock. At present the running expenses of the institution are: Salaries as follows: State Mineralogist, \$250 per month; Secretary, \$150; Chemist, \$125; janitor, \$75; rental of premises, \$175; stationery, postage, printing, freight, fuel, chemicals, gas, etc., about \$125. This foots up to a total of about \$900 per month, or \$10,800 per annum. Taking last quarter's partial revenue, as paid over to the Bureau, \$840.80 as a basis for computation, there will be a deficit of at least \$710.40 for the succeeding 12 months. A table prepared by the Licenses Collector shows the falling off in the 10-cent-per-share tax on stock transfers. The first quarter, ending January 1st, gave a fund for the support of the State Mining Bureau, amounting to \$1,353.98. The second quarter, ending April 1st, shows a decided falling off, but \$840.80 being collected. The tax was collected from the secretaries of 24 mining companies. The largest sums collected were: Alta, \$144 first quarter, \$32.80 second quarter; Mexican, \$95.50 first quarter, \$41 second quarter; Benton, \$97 first quarter, \$19.40 second quarter; Savage \$86.91 first quarter, \$42.80 second quarter. In only three cases did the amount increase in the second quarter over the first—in Eureka Con., \$17 first quarter, \$23.20 second quarter; Mt. Potosi, \$10.60 first quarter, \$33.70 second quarter; Navajo, \$13.30 first quarter, \$62.30 second quarter. A study of the tables result in the conclusion that the decreases in the revenue as collected by the tax of 10 cents per transferred certificate will go on, thus crippling the bureau. The present quarters may have to be given up, and the services of some of the assistants dispensed with in this case.

All mining corporations incorporated under the laws of this State are subject to the tax. There are 8,530 such companies in the State. The sums paid into the State Treasury from this source since the institution of the Bureau, have been as follows: Quarter ending April 1, 1880, \$1,341.60; July 1, \$3,920.60; October 1, \$3,522.70; December 31, \$2,989. Of the first quarter only a portion reverted to the Mining Bureau. It will thus be observed that there has been a diminution in each quarterly return. The revenue for the next quarter will probably show a decrease, according to Mr. Sinton's estimate, of at least 20%.

It is to be regretted that the \$12,000 was not appropriated, as a good deal of the work laid out will have to be abandoned for the present.

#### Mining Districts.

After all, the crucial test and proof of value of any mining region lies in its bullion product. A district may be widely advertised and its population rapidly increased under this influence; its ledges may be large and numerous; its situation advantageous; wood and water abundant; capital advanced to open it, railroads tap it; but if the mines do not produce bullion sufficient to pay expenses and a profit, it will gradually decline.

We should not, therefore, estimate the value of the mining properties of any region so much on the basis of common report or rumor, as on the result of the work. If one sees that the bullion shipments from a mine, group of mines, or district are regular and sustained he can make up his mind that those mines and that district are prosperous, and this may be the case even when little is heard of the mines or district, and when few people are in the vicinity outside of those directly employed.

Because there is a good deal of noise and talk about a district, and a good many people there; a hustling town, and a good many mines showing big assays, it does not follow that that district is going to pan out anything startling. Big assays do not make big mines, any more than talking about building a mill builds a mill.

At the end of the year, when the accounts are balanced, if these mines do not have some kind of a bullion-producing record, they will go to the wall. If their owners can dispose of them before the decline, it is good for them and bad for the purchaser. But for a mine to be a mine, it must produce something. Time was, in flourishing Comstock days, when mines were worked as stock jobbing transactions, the managers of which did not expect any bullion, and not expecting, were not disappointed.

But after the first six months or year of excitement about a region, it must produce bullion to live. After that no amount of advertising or puffing will keep it going without it yields coin. The miners will gauge its possibilities by that time, and will leave it to its fate. Capitalists, too, will follow the miners, as they always do. Capital is never a pioneer. The miners discover, open up and locate; capital follows and develops; and capital is not apt to flourish where miners do not.

The new districts coming to our notice every day, must, then, show us bullion as soon as they can. If they do not, people will drift back into old centers, where they know bullion is being produced, for it is those centers which will remain the most prosperous, even with no "excitement" to back them.

#### Damages from Mining Operations.

In the case of L. L. Robinson vs. Black Diamond Coal Co., decided recently by the Supreme Court, the principle involved was as follows: "The defendant, in working its mine caused deleterious substances to be deposited in a certain creek, whereby the land of plaintiff was injured. The Court held that defendant was liable in damages; and held further that the evidence on the question of damages being conflicting, and the estimate of the court below not exceeding that of some of the witnesses, the finding of the amount of damages would not be disturbed."

A paragraph headed "Mining Debris" has been going the rounds of the press, and was published in this journal among others, commenting on this decision, and giving an abstract of it, which gives an erroneous idea, owing to defective phraseology and a typographical error. It assumes, moreover, that the principles involved in this case are identical with those involved in the debris question, whereas the principles here enumerated are not by any means new. That is to say, the courts have held that where a miner has dumped debris onto a man's land and damaged said land, said miner must pay damages. And the miners have paid damages in such cases, and have purchased lands on which to dump debris.

But, as we have before stated, it is well understood that when the complainant can prove the direct damage from a mining operation, he can recover damages. It will be as well, as this does not seem to be very well understood, to give a resume of the particular case under consideration, as the decision will show how the matter stands.

It appeared by the evidence introduced on the trial of this case, that the plaintiff was, and for a long time had been, owner of a tract of land on the margin of the San Joaquin river, and that the defendant had been for several years prior to the commencement of this action, mining for coal about three miles distant, and at an elevation of 700 or 800 ft. above plaintiff's land. The Quercus creek runs from the mine in a deep gulch or ravine, until it reaches the low lands; and that the water of said creek, during the rainy seasons, is discharged upon and spreads over a considerable area of the plaintiff's land.

But when suit was brought against a number of miners collectively for general damages, the Supreme Court held that individuals must be separately sued and their injury proved upon them directly. That is to say, that where a number of miners threw their debris into streams, and it went upon other men's land, no one could tell what particular debris, or what particular portion came from any particular mine. Therefore damages could not be collected, and the burden of proof of direct damages rested upon the persons upon whose land the debris collected. Failing to prove this direct injury no damages could be collected.

The evidence introduced by the plaintiff tended to prove that the defendant deposited in said creek, at or near its mine coal screenings, ashes and other substances, which, during the rainy seasons, were carried and distributed by the water in said creek upon the land of the plaintiff, and that the value of said land was thereby greatly depreciated.

Judge Sharpetain, who delivered the opinion of the Court (which was concurred in by Judges Myrick, Morrison and Thornton), says:

"If the plaintiff was entitled to recover upon this evidence, the judgment of the Court below cannot be reversed on the grounds of insufficiency of the evidence to justify it, although the defendant introduced contradictory evidence. It is, however, claimed on behalf of the appellant that the plaintiff was not entitled to recover upon that evidence, which, it is said, only shows that the water charged with refuse matter descended upon the plaintiff's land in its natural course, and in obedience to the law of gravitation. If the evidence introduced by the plaintiff did not tend to prove anything beyond that, it failed to establish the defendant's liability for any damage which the plaintiff may have sustained by reason of the overflow of his land. But the plaintiff's evidence, as we view it, tends to prove another and very material fact, viz.: that said refuse matter was the product of the defendant's mining operations, and was deposited in said creek through agencies controlled by the defendant. And that although it is not responsible for the inundation of the plaintiff's land by the water of said creek, it was responsible for the deposit of the deleterious substances with which said water was charged through its agency upon said land. This does not in any manner involve the question of the defendant's right to mine or prosecute any other legitimate business upon its premises. It would not be claimed that the defendant could convey and deposit refuse matter from its mine upon the plaintiff's land by means of carts or cars without incurring liability for any damages which the plaintiff might suffer by reason thereof. And we know of no principle upon which it could be held that a person may escape liability by doing that indirectly which would render him liable if done directly.

"Upon the question of damages the evidence was conflicting, and as the estimate of the Court did not exceed that of some of the witnesses, the finding upon that point cannot be disturbed by this Court."

## History of Gun Cotton and Nitro-Glycerine.

[Written for the Mining and Scientific Press by E. M. KILMER, Chemist.]

## Number Three.

## Chemistry and Production.

All the organic nitro compounds bear in their production from certain organic bodies the same characters—namely, all these nitro combinations are produced from the original body by the exchange of a certain number of equivalents of hydrogen against an equal number of hyponitric acid. For instance:

Cellulose (cotton)  $C_{12}H_{10}O_{10}$  or  $C_{12}H_7O_{10}H_3$  changes into nitro-cellulose or gun cotton,  $C_{12}H_7O_{10}(NO_3)_3$  or  $C_{12}H_7O_{12}N_3$

Glycerine  $C_3H_8O_3$  or  $C_3H_5O_3H_3$  changes into nitro-glycerine  $C_3H_5O_3(NO_3)_3$  or  $C_3H_5O_9N_3$

Carbolic acid  $C_{12}H_6O_2$  or  $C_{12}H_3O_2H_3$  changes into picric acid  $C_{12}H_3O_2(NO_3)_3$  or  $C_{12}H_3O_8N_3$

Mannit  $C_{12}H_{14}O_{12}$  or  $C_{12}H_3O_{12}H_6$  changes into nitro-mannit  $C_{12}H_3O_{12}(NO_3)_3$  or  $C_{12}H_3O_{18}N_3$

Here we have four of the well-known high explosive bodies, and in each case we find three equivalents (or the multiple of three) of hydrogen replaced by three equivalents of hyponitric acid.

Gun cotton looks like ordinary cotton, nitro-glycerine looks like glycerine, and nitro-mannit like mannite, but their chemical properties are vastly different. We shall speak in this chapter of the properties of nitro-glycerine. The nitro-glycerine is produced by the action of concentrated nitric acid on glycerine, during which action the glycerine takes up the nitric acid, and water is eliminated. The chemical reaction is as follows:

$C_3H_8O_3 + 3(NO_3) = C_3H_5O_3(NO_3)_3 + 3(H_2O)$   
Glycerine. Nitric Acid. Nitro-Glycerine. Water.

It is eminently necessary that the nitric acid should be employed in a very concentrated state. In the process of manufacture it is necessary to have the water which is produced in the above reaction absorbed, and that is accomplished by mixing the nitric acid with sulphuric acid.

The practical production of the nitro-glycerine therefore is accomplished by the treatment of glycerine with a mixture of concentrated nitric and sulphuric acid, in which treatment the sulphuric acid plays a secondary role, and by the absorption of the eliminated water it maintains the surplus of the nitric acid in a concentrated condition.

Different chemists employ different proportions in their mixtures of nitric and sulphuric acids, and also in adding the glycerine.

In the production of nitro-glycerine there is a very strong elevation of temperature, which must be avoided, as it may lead to explosions. There are also different methods employed to avoid this elevation of temperature.

According to Sohrero, 2 volumes of sulphuric acid of 1.831 specific gravity, and 1 volume of nitric acid of 1.525 specific gravity, are mixed, permitted to cool, and into this mixture half a volume of glycerine, of a very syrupy consistency, is introduced with constant stirring. The mixture is again cooled, and after having become turbid and been separated into two layers, poured into 15 or 20 times its bulk of cold water. The oily nitro compound sinks quickly to the bottom, is freed from unchanged acid and glycerine through repeated washing with water, and hastily dried in vacuo.

Praeger & Bertram add 1 part by weight of glycerine to 8 parts of a mixture of 1 part of concentrated nitric acid and 2 parts of fuming sulphuric acid.

Liebe recommends to pour 1 part by weight of glycerine into a mixture of 2 parts of nitric acid of 1.525 specific gravity, and 4 parts of concentrated sulphuric acid, to keep the mixture below 75° F., and to dry the washed nitro-glycerine in the steam bath. There are various methods proposed, but on working on a large scale, the process is carried on as follows:

The manufacture of nitro-glycerine usually takes place in three wooden sheds of light structure, separated from one another by strong earth banks of 25 to 30 ft. in thickness at their base. The walls and roof are lined with straw, and the temperature, by means of hot-water pipes, is kept day and night at about 60° Fahr.

In the one shed the glycerine is brought together with the mixture of acids; in the second shed the nitro-glycerine is poured into the water, and otherwise washed; in the third shed the complete elimination of acid from the oily compound is effected, and eventually the nitro-glycerine is worked up into dynamite.

These sheds are sunk into the ground, so that their flat roofs are barely above the level of the ground, they are lit up by reflecting lamps placed outside on the roofs; the floor is covered with fine sand. At some distance from these sheds are the huts in which the cartridges are made. They, too, are separated from one another through earth banks, and so is another shed, in which the packing takes place. Quite away from all these buildings are the store-houses, sunk into the ground. There are usually also cellars for keeping the ice, which latter serves for cooling the wash water. The storing of the raw glycerine and the sulphuric acid requires no special precaution.

Nobel's arrangement for making nitro-glycerine is very perfect, as large quantities can be produced by it at a time, as much as 3,500 lbs. in one operation, and to accomplish it, only a few

hours are required, and under the supervision of an able man the operation can be considered comparatively safe, as he keeps his mixture cool, and avoids in this way the great danger of the nitro-glycerine igniting and causing explosions. I shall enumerate the way the nitro-glycerine is manufactured in some large establishments on the Continent.

In one of the largest dynamite factories in Europe, where the daily production is over two tons, the nitro-glycerine is prepared in the following manner: 1,300 lbs. of nitric acid of the specific gravity 1.48 are mixed in four cast iron pans with 2,600 lbs. of sulphuric acid; this mixture, which is left to cool for a day, serves for the treatment of 630 lbs. of glycerine. This acid is drawn from the pans into a wooden cylindrical vat, of about six ft. high and three and one-half ft. in diameter, lined inside with thick lead and containing along its lining two spiral lead pipes of about one inch diameter, which reach from the bottom to the top. Each of these spirals, or worms, forms a system by itself through which cold water circulates, and one may serve as substitute for the other in case one gets out of order. The mixture of acids is stirred first by itself in this vat; the stirring is effected by two iron disks covered with lead, disk and covering being perforated, which glide up and down on a vertical iron shaft, the gliding motion being effected by pulling the rope attached to the disks over a pulley; the two or three workmen who perform this task stand at a distance of 30 or 40 ft. from the vat, behind a strong earth bank. When the acids have been introduced into the vessel, and the agitation has commenced, water of the temperature of about 25° F. is let into the worms, the temperature of the acid in this way being maintained at about 50° F., as may be ascertained from a thermometer which reaches through the lead cover of the vessel into the acid. The glycerine, which is kept in a zinc tank on the roof of the shed in which the mixing vat is, is now allowed to run into the latter vessel. The flow is regulated by means of a tap, and also by letting the glycerine first run into perforated zinc boxes, placed on the lid of the mixing vat, and corking up, if occasion requires, some of the perforations. As soon as the glycerine falls in-

to the acid the temperature rises at once, but by carefully regulating the supply of glycerine it may be kept at about 60° Fahr.

It is advisable not to allow the temperature to rise above that degree, though experience shows that a higher temperature yields a larger quantity of nitro-glycerine. It requires, according to the season and the temperature of the cooling water, two to three hours for 630 lbs. of glycerine to pass into the mixing vat; the stirring must not be stopped for a moment during the process. When all the glycerine has been added to the acids, the mixture is at once drawn off through a leaden pipe to the so-called wash shed, where it passes into a tank about eight ft. high and 12 ft. in diameter, which is half filled with cold water.

The inlet tube carries a sieve, to retain lead sulphate that may have been brought from the mixing vat. Whilst the nitro-glycerine flows in, stirring with wooden poles is begun, and continued until the nitro-compound has settled below the dilute acid. The bottom of the wash tank is slightly inclined, so as to allow a complete drawing off of the nitro-glycerine. The outlet taps are of stone-ware. The nitro-glycerine is now twice washed with water, freed from acid and lead sulphate, and finally washed with water, to which some sodium carbonate has been added.

But even after this purifying process there remain traces of acid; to eliminate these the nitro-glycerine is transferred to a third shed, where it is agitated for about an hour in a rotating vessel called a butter machine, with about 50 lbs. of a concentrated solution of sodium carbonate; after this time it will no more reddens litmus paper. It is now separated from the alkaline solution, filtered through felt, and collected for further use in leaden reservoirs.

The yield differs greatly according to the condition of the raw glycerine, the concentration of the acids, and the temperature. The yield of nitro-glycerine falls generally below the theoretically calculated quantity. This shortcoming is due to the formation of glycerides, which dissolves in the wash water. As a rule, the yield in winter is greater than that in summer.

The above is a system employed by some continental manufacturers, and notwithstanding the precautions taken against the accidental rise of temperature during the production and washing of the nitro-glycerine, some very serious explosions during its manufacture have not

been unfrequent; but Nobel has adopted a method of operation which, so far as experience goes, appears not to involve any special elements of danger if properly applied, and also presents advantages from an economical point of view, besides promoting the attainment of uniform results; and to his credit it must be said that when he made his first trial with his new apparatus he certainly exhibited a great deal of boldness and pluck, as it was a question of converting several hundred weight of glycerine into the explosive compound in a single operation. His mode of operation is successfully carried out by the Giant Powder Co. of San Francisco. The plan pursued by some of the other companies established near this city differs somewhat in its arrangement.

A series of small iron kettles, or pots, are arranged in a trough, each provided with a stirrer, which receive their movement from a common shaft which is revolved by a man stationed outside of the building. The pots are charged with the acids, and the glycerine is supplied either from a common reservoir by small outlet pipes, or above each pot is a small vessel containing glycerine, from which the same runs in a small stream into the acid mixtures.

The iron pots are surrounded by a running stream of cold water while the reaction is going on and stirring has to be constantly kept up. After the reaction is complete the pots are taken up and their contents dumped into large tanks filled with water, where the nitro-glycerine separates and is afterwards washed.

As simple as this operation may appear, the writer earnestly warns anybody who is not experienced in the matter to undertake any trials, as there are points connected with the manufacture of nitro-glycerine which can only be acquired by practical experience, and even then it is fraught with danger.

In the next issue, Mr. Mowbray's, of Mass., process of manufacture will be given, as it has certain features worthy of note.

NEW MAIL FACILITIES.—Within the past 30

days there have been 64 new postoffices established on the Pacific coast, and there have been 33 discontinued. During the same time, Wells,

Fargo & Co.'s express has established 51 new offices, and discontinued but one. These figures show that new regions are being settled up rapidly on this coast, as around each one of these postoffices, a community has grown up which demanded the mail and express facilities.

We see by the Pacific Coast Postal Index, that there have been in the same time 45 changes in the arrival and departures of mails at this city, which is mainly owing to the new overland mail connection by the southern route. There have also been 120 changes in foreign postal rates, affecting third and fourth-class matter. Five countries have entered the postal union in the last 30 days.

"SMALL MINERS."—The following item, from the Oroville Mercury, is suggestive to those persons who sit around bar-room fires and growl about hard times all winter. "Men are coming into this city every day with small batches of gold dust that they have taken out of their claims in the foothills in the winter. The claims are generally in the bed of small creeks, and if their owners were able to bring water to them, would prove valuable property. A person has no idea of the amount of gold taken out during the winter months by these small miners. Some of them bring it here and sell it to the bank. But a large number carry it to the nearest stores and trade for provisions. The season, however, is nearly over, and they must quit work until the next rains."

MINING PATENT DECISION.—In the Leedville, Col., case of the Com promise lode against the American lode, the Secretary of the Interior has decided that objection to the prima facie sufficiency of an adverse claim, received and filed by the Register within the period of publication, cannot be heard in the Department when the party has allowed the 30 days prescribed by law for the commencement of legal proceedings to expire before presenting such objection, and has actually been brought into Court upon the suit of an adverse demand. In such a case, the proceedings for a patent will be stayed to await the judgment of the Courts, and all defenses must be presented to those tribunals expressly authorized by the United States statutes to try the question of the right of possession.

## The Pelton Water Wheel.

The engravings on this page represent the water wheel recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by L. A. Pelton, of Camptonville, Yuba Co. Cal. Fig. 1, shows the wheel on its frame with the nozzles, and the small engraving under it shows the bucket. Fig. 2, is an enlarged view of the peculiar buckets, on which the efficiency of the wheel depends. The buckets are three times the stream's diameter in width. Under heads of water of 75 to 800 ft., the inventor guarantees this wheel to excel the turbine or other wheels. The following are the conditions under which it was tested, as given us by Mr. Pelton:

"The work done was measured with a Prony dynamometer. The fall of the water was accurately ascertained; its velocity at the nozzle was 93% of that due to gravity, seven per cent. being lost by friction in the conduit. After leaving the wheel the water was caught in a tank, and the cubic ft. used ascertained. Under the above conditions, this wheel utilizes 78% of the theoretical power, which per cent. will be found in the tables of horse-power. With a conduit of suitable size, the friction would have been less, and the wheel's per cent. of efficiency greater. The above result is due to the peculiar shape of the buckets used; they do not reduce the water to a spray, but divide and deflect it outward and backward, in such a manner that a part of the impact and the whole reactionary force are utilized without any part of the water coming in contact with the bucket following—a decided improvement on buckets heretofore used. Furthermore, the per cent. of efficiency remains constant through great variations in the amount of water used—another important factor in the make-up of a good wheel. These buckets can be taken off in transportation, thus avoiding breakage; and, when worn out by sand in the water, can be replaced by new ones; also can be applied to wooden wheels when desired."

To those desiring it, Mr. Pelton will send a circular in which is a table giving the diameter, revolutions, water used and horse-power of the various sizes of wheel, under different heads.

These wheels are not expensive, the smallest sized ones being about \$60, and from that up to \$375, the price including shaft, pulley box bolts, nozzle and gate. For miners' use this wheel seems very handy and well adapted. It can, of course, be put to any work for which wheels are used.

## Advertising Mining Companies.

We have been credited here in California with blowing our own horns pretty well, and making the most of what we have. And we have also been credited with sharp ways of doing business in mining stock transactions; and it has been further stated of us that we have a happy way of putting our mines on the market in an attractive style, so that the less valuable the property is the more likely it is to sell well. We will make a partial acknowledgment of these things, but we will, for once, confess ourselves outdone by the East in the matter of advertising mines and stock. We have come across one example in a circular which arrived on the benighted Pacific coast this week from New York, which shows us that we are to be taught, among other things, how to float mining shares. Leaving out the large type, the display lines, and the name of the company (unimportant features), here it is:

"There is a tide in the affairs of men, which taken at the flood, leads on to fortune." A fortune is within your reach! Put forth your hand and grasp it firmly at once. Blank Mining Co., incorporated under the laws of the State of New York. Principal office, N. Y.

Write immediately for a prospectus, which contains full information regarding the great enterprise which is interesting to the entire civilized world.

This opportunity is now offered for a short time only—a limited amount of the stock of the company is for sale at only \$2 for a full share. By investing in this enterprise you are certain to make money, and will become identified with the greatest interest in the world.

"Do not let your chances, like sunbeams, pass you by."

Every stockholder can rely upon making money.

The company, when they have provided sufficient capital to put up a 20-stamp mill, can earn profits sufficient to give every stockholder 30% dividends, and place additional stamps on the property, which, within two years, will probably enable them to earn 100% to 150% dividends on the stock.

Every dollar invested will represent a dollar in property; and, when stocked with machinery, the property will be worth many times its cost.

Full information furnished by addressing, etc.

We think this advertisement is a little ahead of anything ever seen on this coast. It will probably be noticed that it omits any mention of such unimportant facts as location of the mine, number of shares, size of vein, depths of shaft, etc., class of ore, whether gold or silver, etc.; but it sounds well, and, moreover, has a quotation from Shakespeare. Even the names of directors and superintendent are omitted. Some persons may think we are joking, but this advertisement is a bona fide one, and we give it as an example of the way such things are managed by some people in the East.

THE PELTON WATER WHEEL.

**GLUE.**—A glue ready for use is made by adding to any quantity of glue, common whisky, instead of water. Put both together in a bottle, cork it tight and set it for three or four days, when it will be fit for use without the application of heat. Glue thus prepared will keep for years, and is at all times fit for use, except in very cold weather, when it should be set in warm water before using. To obviate the difficulty of the stopper getting tight by the glue drying in the mouth of the vessel, use a tin vessel with the cover fitting tight on the outside to prevent the escape of the spirit by evaporation. A strong solution of isinglass made in the same manner is an excellent cement for leather.

**RAILROAD MEN'S WAGES.**—Conductors in the Oregon Railway & Navigation Co.'s service receive \$95 per month; engineers, \$90, \$100 and \$125; brakemen, \$66; firemen, \$66; Chinamen, \$1 a day, board themselves; white men, \$1.85 a day.—*Ec.*

Nevada railroad men are the best paid in the world, excepting perhaps, those on the Isthmus of Panama. On the Central Pacific conductors get \$115 a month; freight conductors, \$90; brakemen, \$70; engineers, \$4.69 a day; firemen, \$2.80; Chinamen, \$1; white men, \$2. On the V. & T. R. R. engineers get \$5 a day.—*Reno Gazette.*

**THE RIGHT WAY.**—The Arizona Mining Journal calls attention to a feature in Meyer's district and says: "This feature, which calls for special notice, is the earnestness of those engaged in developing the mines. They do not bore the visitors at every corner with the fabulous wealth hidden in their prospects, but have gone honestly to work to find out for themselves what they have under ground. This is the true policy, and it will be found to pay well in the end."

The former Mission of Tucson, Arizona, was probably founded in 1750 or 1751. Tumacacori and Calahasas were founded about 1754; Puelita and San Andreas about 1798, and San Pedro (Fort Yuma) and San Pablo, about 1780.

**TAMERLANE.**—Joseph Tomson, over from Tamerlane for the first time in several months, reports that he has developed a vein of ore seven ft. wide in the Baltimore, and has taken out several tons of ore that will go about \$150.

In Pinal county, Arizona, since 1875, there have been 2,334 mining locations recorded, and 2,521 transfers of mining property have been made.

## Business Directory.

WM. BARTLING. HENRY KIMBALL

E. & F. N. Spon, 446 Broome St., N. Y.

## MOREY & SPERRY,

MANUFACTURERS OF

### Gold and Silver Grinding and Amalgamating Machinery

**HOWLAND'S PULVERIZER** Takes the Place of the Cumbrous Stamp Mill and can be put up in one day ready for work.

IT HAS BEEN FULLY PROVED AND TESTED.

It weighs complete, 7,000 pounds. It costs \$1,500 ready for the belt. Will crush one ton of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill. It requires twelve-horse power.

Stamp Mills' Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supply. Iron Work complete for Wood Frames, also

**SPERRY'S  
WROUGHT IRON FRAME  
FOR STAMP MILLS.**

Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.

**MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.**

## THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

### HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

**No. 1 XX is the Strongest Explosive Known.**

**No. 2 is superior to any powder of that grade.**

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - - San Francisco, Cal.

### LEFFEL'S IMPROVED WATER WHEEL.

PRICES REDUCED!

PATENTS REISSUED 1868.

The "OLD RELIABLE" with improvements, making it

THE MOST PERFECT TURBINE NOW IN USE.

Comprising the Largest and the Smallest Wheels, under both the Highest and Lowest head used in this country. Our new Illustrated Book sent free to those desiring water power.

Those improving water power should not fail to write us for New Prices, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address

**JAMES LEFFEL & CO.,** Springfield, Ohio,  
and 110 Liberty St., N. Y. City.

**PARKE & LACY, Sole Agents, 21 and 23 Fremont St., S. F.**

**STEEL CASTINGS**  
FROM 1-4 TO 10,000 lbs. WEIGHT.  
True to pattern, sound and solid, of unequalled strength, toughness and durability. An invaluable substitute for forgings or cast-iron requiring three-fold strength. Gearing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc. 15,000 Crank Shafts and 10,000 Gear Wheels of this Steel now running prove its superiority over other Steel Castings. CRANK SHAFTS, SHOES, DIES and GEARING specialties. Circulars and Price Lists free. Address  
**CHESTER STEEL CASTING CO.,**  
Works, CHESTER, Pa. 407 Library St., PHILADELPHIA

### MENZO SPRING.

Manufacturer of the Best

Improved Artificial Limbs.

OFFICE AND ADDRESS:

9 Geary Street, Junction of  
Market and Kearny, S. F.

### EXOTIC GARDENS.

Mission Street, opposite Woodward's Gardens, Branch, 1029 Sutter St. These Gardens have been Newly Stocked with a First-class assortment of the very best and most select plants for Conservatories or Open Grounds.

Prices have been reduced to suit the times. Bouquets, Funeral Works and Cut Flowers furnished at short notice.

**J. POUYAL, Proprietor,**

All are invited to examine our stock.

This paper is printed with Ink furnished by Chase, Eneu Johnson & Co., 509 South 10th St., Philadelphia & 59 Gold St., N. Y. Agent for Pacific Coast—Joseph H. Dorsety, 527 Commercial St., S. F.

### P. H. McGrew, Carriage and Wagon

MANUFACTURER.

Nos. 1056, 1058 and 1060 Thirteenth Avenues,

EAST OAKLAND, CAL.

### California Inventors

Should consult DEWEY & CO., AMERICAN AND FOREIGN PATENT SOLICITORS, for obtaining Patents, Caveats and Trademarks. Established in 1860. Their long experience as journalists and large practice as patent attorneys enables them to offer Pacific Coast inventors far better service than they can obtain elsewhere. Send for free circulars of information. Office of the MINING AND SCIENTIFIC PRESS and PACIFIC RURAL PRESS, No. 202 Sansome St., San Francisco.

**J. H. WYTHE, M. D.**

Residence: 965 West Street, Oakland. Office: 759 Market St., San Francisco. Before 10 A. M., after 5 P. M. From 11 A. M. to 3 P. M.

### Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

### THE IMPROVED INGERSOLL

### Rock Drill and Air Compressor.

The undersigned having been appointed sole agent for the Pacific coast, will keep always on hand a large stock of the various sizes, together with duplicate parts, all of which he will sell at factory prices. The Ingersoll is the only Rock Drill now in use on the Comstock.

**GEO. R. FOARD, SOLE AGENT,**  
No. 13, First St., S. F.

Send for a Catalogue.

### Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

**Concentration of Ores** (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniures, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50

**ROASTING OF GOLD AND SILVER ORES** (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1880.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 156 pages, embracing illustrations of furnaces, upholders and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3.00 coin, postage free.

### EXCELSIOR BLASTING POWDER

MANUFACTURED BY THE

Excelsior Powder Company.

This is no so-called "safety" Powder, but a powerful explosive, and as safe to handle and use as any nitro-glycerine powder on the continent. There is no headache or nausea in the use of this Powder, as the noxious fumes are entirely done away with. It is put up in cartridges of any size to suit consumers and is exploded with cap and fuse, the same as any other high explosive. The following testimonial is a sample of hundreds of the same tenor being constantly received:

GOLD HILL, August 17, 1880.

AGENT EXCELSIOR POWDER CO.—Dear Sir:—I have used your Powder in test cement and hard blasting rock, and find it superior to any Powder in use on the Comstock. It does its work effectually, and does not leave the person using it with a severe headache, like the other Powders do to the majority of miners. In recommending it I would suggest, give it a fair trial and I am confident it will speak for itself. Wishing your Company success,  
I am respectfully yours, etc.,

GEORGE CLARK,

Foreman Sierra G. and S. M. Co.

Address all orders to

**Excelsior Powder Company,**  
Room 40, Merchants' Exchange,  
SAN FRANCISCO, CAL.

### New Book on the Comstock.

The attention of MINING ENGINEERS and EXPERTS is called to the new work by JOHN A. CHURCH, E. M. PH. D., on "The Comstock Lode, Its Formation and History." This very exhaustive treatise on this famous lode is fully illustrated with diagrams and colored charts showing sections, ore bodies, etc., and will be of great interest and permanent value for reference. DEWEY & CO., Publishers of the MINING AND SCIENTIFIC PRESS, are sole agents for the sale of the work. Mr. E. M. SLEATOR will act as their agent, and call on Mining Engineers and those interested in the great lode in this city with a copy of the book for their inspection.

## Metallurgy and Ores.

**WM. D. JOHNSTON,**  
[Formerly Chief Assayer with Thos. Price.]  
**ASSAYER AND ANALYTICAL CHEMIST,**  
118 & 120 Halleck Street,  
Near Leldesdorf, SAN FRANCISCO.  
ASSAYING TAUGHT.

Personal attention insures correct Returns.

### Nevada Metallurgical Works,

No. 23 STEVENSON STREET,  
Near First and Market Streets, S. F.  
ESTABLISHED, 1869. C. A. LUCKHARDT, Manager.

Ores Worked by any Process.  
Ores Sampled.  
Assaying in all its Branches.  
Analyses of Ores, Minerals, Waters, Etc.  
Working Tests (Practical) Made.  
Plans and Specifications furnished for the most suitable process for working Ores.  
Special attention paid to Examinations of Mines, plans and reports furnished.

C. A. LUCKHARDT & CO.,  
(Formerly Huhn & Luckhardt.)  
Mining Engineers and Metallurgists

### JOHN TAYLOR & CO.,

IMPORTERS OF AND DEALERS IN

**ASSAYERS' MATERIALS,**  
**MINE AND MILL SUPPLIES,**

**CHEMICAL APPARATUS AND CHEMICALS, DRUG-  
GISTS' GLASSWARE AND SUNDRIES, Etc.**

118 and 120 Market Street, and 15 and 17  
California St., San Francisco.

We would call the attention of Assayers, Chemists,  
Mining Companies, Milling Companies, Prospectors, etc.,  
to our full stock of Balances, Furnaces, Muffles, Crucibles,  
Scorifiers, etc., including, also, a full stock of  
Chemicals.

Having been engaged in furnishing these supplies since  
the first discovery of mines on the Pacific Coast, we feel  
confident from our experience we can well suit the demand  
for these goods both as to quality and price. Our  
New Illustrated Catalogue, with prices, will be sent on  
application.

Our Gold and Silver Tables, showing the value per  
ounce Troy at different degrees of fineness, and valuable  
tables for computation of assays in grams and grammes,  
will be sent free upon application. Agents for the Patent  
Pumhago Crucible Co., London, England.

SHEET IRON PIPE.

## FRANCIS SMITH & CO.,

Manufacturers of

**THE PATENT CHANNEL IRON WHEELBARROWS.**

THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and  
of the best material. All sizes kept constantly on hand.

### SHEET IRON PIPE.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe.  
Also, Galvanized Iron Boilers, from 25 to 100 Gallons.  
Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools  
supplied for making Pipes. Estimates given when required. Are prepared for coating all size of  
Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

### PACIFIC MACHINERY DEPOT.

## H. P. GREGORY & CO.,

Nos. 2 and 4 California Street, San Francisco.

Importers and Dealers in every description of

## MACHINERY!

Sole Agents for the Pacific Coast for

## BUCKEYE Engine Company.

J. A. Fay & Co.'s Wood-Working Machinery; Bement & Sons' Machinists' Tools; Blake Steam Pumps; N. Y. Belt-  
ing and Packing Co.'s Rubber Goods; Sturtevant Blowers and Exhaust Fan; Taithe Co.'s Emery Wheels and Ma-  
chinery; Payne's Vertical Engines and Boilers; Perry's Centrifugal Pump; Judson's Standard Governors; Dreyfus  
Self-Oilers; Gould Mfg. Co.'s Hand and Power Pumps; Eclipse Windmills; Disston & Sons Circular Saws; Otto  
Silent Gas Engine; Dues' Elevator Cups; Ballard's Oak Tanned Belting.  
Also on hand and for sale A FULL LINE OF MILL AND MINING SUPPLIES.

## GOLD MINERS

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

### Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

**SPOKE-SHAVE.**—Louis Bauer, S. F. Patented April 12, 1881. No. 240,076. This improvement in spoke-shave consists in a novel method of holding and clamping the blade of the shave in place between two clamping jaws, so that every style of blade may be held in place and may be adjusted to or from the plate or cage, which serves as a gauge. The invention further consists in a means for setting the blade to or from the gauge plate, so as to regulate the cut. The construction patented enables the inventor to use a rough stick for a number of cutters, and they may be worn down to a narrow blade before being cast aside. The tool is especially valuable for working leather on account of its delicate and easy adjustment.

**TIRE UPSETTER.**—John E. Tiffen, Redding, Cal. This invention relates to a tire upsetter or shrinker, the novelty of which is in a peculiar arrangement of parts whereby one actuating lever is made to do the work, the whole being simple and easy of construction, combining with these advantages great strength without great weight. A base bar is bolted to a bench or block; this bar has diverging arms, to the ends of which other arms are pivoted, being made to converge, and are pivoted together and are also fastened to a slide having guides, the same pivot being made to join the arms together, and both to the slide. The tire is placed in jaws formed by the extreme ends of the arms and clamps having a corrugated surface. This device gives great power and is operated by one movement of the lever.

**WAGON BRAKE.**—David E. McKee, Potter valley, Mendocino county, Cal. Patented April 12, 1880. No. 240,160. This improvement in wagon brakes consists in so constructing the brake that it may be operated by the weight of the wagon bed and load. On the front bolster is a roller, and the rear bolster is a rocking one, the body resting on the rocking bolster and the rollers. From this rear rocking bolster extend levers, bent downward. In front of the rocking bolster is a roller journaled on staples, said roller being provided with downwardly projecting cranks. Rods connect with both pairs of downwardly projecting levers, and connect with the brake bar. When the wagon is going down hill the weight of the body, with or without a heavy load, will cause it to slip forward, the roller permitting, and will draw the levers so as to put on the brake. The brakes being on the running gear can be used for any wagon simply by changing the bed. Stops prevent the bed going too far ahead or back. A foot brake attachment is also used with them for stopping on an up grade.

Fifty guns were fired at Prescott, Arizona, in honor of the court's decision in favor of the California Mining Co.

### Wood River.

CONTINUED FROM PAGE 257.

A correspondent of the Eureka Sentinel has this to say about the route. "A word of advice to those who desire to come to this region. I see that there are a good many axes to grind by station-keepers and ferrymen. It is generally conceded here that, while travelers are able to come from whatever direction they choose, the route via Ogden and Blackfoot is the only feasible and comfortable one. It saves a number of hours of hard staging, and actually the shortest by from 40 to 50 miles. It also avoids this possible danger of spring floods and consequent delay. Besides, it passes through an interesting country. But I am not capping for any stage line."

Another correspondent, this time of the Carson Appeal, who went by the route mentioned, gives the following charges: "The fare from Carson to Blackfoot, including meals and sleepers on the Central Pacific and Northern railroads, is \$66.75, apportioned as follows: Carson to Reno, \$2; Reno to Ogden, \$44.75; Ogden to Blackfoot, \$16; meals, \$4. The stage fare from Blackfoot to Bellevue is \$25; meals, \$1 each, and lodgings (on the floor of a log cabin), 75 cents per night."

One feature of this region is an attractive one to miners, and is, perhaps, one of the principal reasons for the rush, viz., the mines are rich on the surface, and the country has not been much prospected. The ore can be easily and economically smelted. The veins are from one to two ft. wide, and the ore averages from \$70 to \$100 per ton. The principal town, Bellevue, some people think will take rank with Leadville or Tombstone, in its sudden enlargement. But Bellevue does not take all the visitors. There are many camps lying contiguous and tributary to it, that they absorb the surplus population, and one hardly knows whether the strangers have gone. An old Nevada county miner, G. W. Hobart, writes from Bellevue to H. A. Lord, of Nevada City, a letter which is published in the Transcript, from which we take the following facts:

"I arrived here on the 5th, eight days from Kelton, and it was a rough trip you bet, walking and pushing a horse over the 45 miles between Little Wood river and this place. We had to wade in mud and water belly deep in some places. Meals on the road are miserable and cost a dollar apiece. There is very little food on the table and it is dirty at that. Bellevue is a good place for its age, being situated on a bench overlooking Wood river and in front of the mountain, and containing about 500 people. The population is rapidly increasing, and as soon as the roads are in good condition I am satisfied there will be the greatest rush to the place ever seen on the Pacific coast. Old prospectors say there is a mineral belt 200 miles long and 60 wide. That being the case there will be room enough for all who come."

"The ledges here remind me of those in the Austin district. As far as prospected they show small pockets assaying from \$100 to \$2,000 a ton. The ore can be sold on the ground for 90% of the assay value after deducting \$40 a ton for transportation and working. It is heavy in galena and hornblende. Many locations have been made, but not much thorough prospecting done. "The snow is all gone in Bellevue, and the most of it has disappeared from the west side of the foothills. Above the foothills there is too much for prospecting."

There is hardly any doubt but that most of the miners will get there too early to do the work they expect to, but as most of them have made up their minds already as to when to start, it is scarcely worth while to say much. Neither is it probable that any advice as to staying where they are if they have any steady engagement, would be listened to. We therefore content ourselves with giving as much information concerning the country as we have been able to gather; and print also the mining laws of the Territory.

### The Mining Laws of Idaho.

As a great many persons are now going to the Wood River, Sawtooth and Yankee Fork regions, in Idaho, it is just as well for them to know what the mining laws of the Territory of Idaho are. We therefore append them in full, as passed by the Legislature in February of this year, so anybody going there can clip them out for future reference:

*An Act relating to the location and recording of mining claims.*

SEC. 1. The mining claims heretofore located upon veins or lodes of quartz or other rock in place bearing any of the precious or other metals, mentioned in section 2,320 of the Revised Statutes of the United States, may extend three hundred (300) ft. on each side of the middle of the vein or lode: Provided, That where the locators have set their stakes, posts or monuments, described in the next section, to indicate the line of the vein, ledge or lode, said stakes, posts or monuments shall be taken for the purpose of said location, to mark correctly the line thereof, and each line shall not be afterwards changed so as to affect the rights acquired or interfere with any location made subsequent thereto.

SEC. 2. The locators of any mining claim shall at the time of making the location place a substantial stake, or post, not less than four inches

squares, or in diameter, at each end of the ground claimed and as near as practicable along the course, or line, of the vein, or lode, and also a similar stake, or post, at each corner of the location. Such stakes or posts shall be at least four ft. high above the surface, and shall be marked distinctly with the name of the claim. The notice of location heretofore mentioned, shall be conspicuously attached to one of said centers and posts, so that the same may be easily read; or it shall be conspicuously posted in like manner at the point of discovery and prospecting work on the claim. Where stakes or posts cannot be conveniently had, well-built monuments of stone of the like height above the surface will answer the purpose of stakes or posts, but the notice must be so placed on the side of said monument as to be read easily.

SEC. 3. The notice shall contain the date of the location, the name of the locators, the names of this claim, ledge or lode, the quantity in ft. claimed along the ledge or lode, the width claimed from the middle of vein, and shall also give such a description of the locality of the claim, by reference to natural landmarks or fixed objects, and contiguous claims, if there be any, so as to render the situation of the same reasonably certain from the letters of the notice itself.

SEC. 4. Every claim shall be recorded within fifteen (15) days from the time of the posting of the notice, in the district in which the same shall be located, or at the nearest office to the claim. For the convenience of the prospectors and locators, the County Recorder of the several counties shall appoint a deputy at any place where he may deem it necessary, and at all places more than ten (10) miles distant from an existing office, whenever ten or more mining locators interested, shall petition for the appointment of such deputy. Upon the failure of any Recorder to make the appointment of a deputy for ten days after a petition in writing shall have been presented to him, the resident miners at such district may appoint temporarily one of their number to act as Recorder of the district, whose records shall be as valid as if made by a deputy, and whose records shall be entered by the Recorder, as herein required. Provided, That whenever at any time afterwards the Recorder shall appoint a deputy for such district or place, the authority of the person elected by the resident miners shall cease.

SEC. 5. At the time of presenting a notice of location for record, or within five (5) days thereafter, one of the locators named in the same, shall appear before the deputy, and make and subscribe an affidavit in writing, on or attached to the notice to be administered by said deputy, substantially in the following form, to-wit:

Territory of Idaho, County of —, SS. I, —, do solemnly swear that I am acquainted with the mining ground described in the notice of location herewith, called the — ledge or lode, or claim, and that the ground and claim therein described, or any part thereof, has not, to the best of my knowledge and belief, been heretofore located according to the laws of the United States and of this Territory, or if so located, that the same has been abandoned or forfeited by reason of the failure of each former locator to comply with the requirements of said laws.

Subscribed and sworn before me this — day of —, A. D. 18—. A. B.—

SEC. 6. The notice herein required to be recorded is a copy of the notice placed on the claim, or substantially a copy of the same. It shall be recorded by the deputy appointed for the purpose as above provided (when the legal fee therefor shall be tendered) in a book, to be kept for that purpose. Said book shall be indexed with the names of all locators arranged in alphabetical order, according to the first or surname of each. The fee to be tendered for making said record, administering the oath to the locator, and certifying the same, for indexing the names appearing upon the notice, and to include the recording of the notice by the recorder, as hereinafter required, and the indexing by said recorder, shall be three (3) dollars, which fee shall be equally divided between the recorder and the deputy, or person acting under an election, as herein provided; and no other or additional sum of money shall be demanded or received by either or any of them for any services connected with the recording of any notice of location made pursuant to the requirements of this act.

SEC. 7. The deputy recorder of mining claims of each district, or the person elected as hereinabove provided to make the record in case of the failure of the recorder to appoint a deputy, shall at least once in each month, transmit to the recorder, at the county seat, all the notices of location filed with him for record and not previously transmitted, which shall at once be recorded by said recorder, in a book to be kept in his office, and be known as the Book of Mining Claims. The names of all persons appearing in every notice of location shall be indexed by the recorder, said names being arranged in said index in alphabetical order, according to the first letter of the surname of said locator.

SEC. 8. The deputy recorders provided for in this act shall not, by virtue of the provisions hereof, be authorized to perform any other than the special duties herein specified. They shall keep an official seal, and the records in their custody shall be public records, but the seal of a deputy recorder shall not be attached to any paper except for the purpose of authenticating certificates attached to transcripts of the records in his custody as such deputy recorder.

SEC. 9. Any person who shall willfully and ma-

liciously tear or take down or destroy any notices posted on any claim, or remove or take down any stakes, post or monument placed or erected for the purposes of marking or indicating any mining claim or the line of the vein, ledge or lode, with the intent to destroy or impair the evidences of such location shall be deemed guilty of a misdemeanor, and on conviction thereof before any Justice of the Peace of the county may be punished by fine in any sum not exceeding \$100 or imprisonment in the county jail not exceeding six months, or by both fine and imprisonment.

SEC. 10. An act relating to the discovery of gold and silver quartz lodes and of the manner of their location, approved January 12, 1866; an act supplemental to and amendatory of said act, approved January 14, 1877; an act relating to the recording of quartz claims in Owyhee and Alturas counties, and fixing the fees thereof, approved January 15, 1875; an act relating to the discovery of gold and silver quartz lodes in Lemhi county and the manner of their location, approved January 9, 1877; an act relating to the discovery of gold and silver quartz lodes in Lemhi county and the manner of their location, approved February 21, 1879, and all other acts and parts of acts in conflict or inconsistent with the provisions of this act, are hereby repealed. Approved February 10, 1881.

### News in Brief.

BENJAMIN DISRAELI, Earl of Beaconsfield, died this week.

THERE is great suffering and destitution in many Dakota towns.

POLICE officer Denniston, of this city, committed suicide by poisoning, this week.

PROSPECTORS are hitting out at San Diego for a trip one hundred miles into Mexico.

An insane mother at Camden, Ark., drowned her five children by throwing them down a well.

The first regular train over the Carson and Colorado railroad came through to Bodie on the 18th.

SAN FRANCISCO Chamber of Commerce is discussing bills for prevention of food adulteration.

The doctors and sailors from American ships particularly distinguished themselves in tending the wounded at Seio.

The public schools will close this year on the 27th of May, and the Boye' High school will close one week sooner.

The steamship Oceanic is lying in quarantine in this harbor, small-pox having broken out among the Chinese passengers.

COL. WILLIAM W. GIFT, a well known California pioneer, and noted for his appreciation of fine horses, died this week at Martinez.

THERE are 121 small-pox patients in the New York hospital, an increase for the week of 31. Typhus fever patients, 103, an increase of 47.

THERE is a strike of the plantation hands in St. Bernard Parish, Louisiana. The Governor has been called upon to quiet the disturbance.

MILLER & Lux are shearing 80,000 head of sheep at their ranch at Firebaugh Ferry. They will have the wool graded and ship it direct to Boston.

The manager of the Chestnut-street opera house, Philadelphia, has been instructed to begin a suit against Anna Dickinson for refusing to appear as Claude Melnotte.

It is stated that John Hay, ex-Secretary of State, will take Whitelaw Reid's place as editor of the New York Tribune, for four years from May 1st next. Reid is going to Europe.

NAPA's City Board of Health attempted to build a pest house in the county infirmary lot. Many citizens objected to this, and the building was torn down and scattered along the road.

A NEW ORLEANS dispatch says that the State Board of Health requests the Governor to issue a proclamation establishing quarantine from May 1st against ports infected with yellow fever.

### Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct (or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omission of agents.

### Pocket Mining Atlas,

Containing the principal mining districts in the United States. Compiled from the latest official surveys and the most authentic sources by Edwin Bolitho. Sent, post-paid, on receipt of \$1. Address, Dewey & Co., 202 Sansome St. S. F.

PERSONS receiving a sample copy of the MINING AND SCIENTIFIC PRESS with this notice marked, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We will send it, on trial, at the rate of \$4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

HOW TO STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

BY TELEPHONE.—Subscribers, advertisers and other patrons of this office can address orders, or make appointments with the proprietors or agents by telephone, as we are connected with the central system in San Francisco.

Our Agents.

Our Agents can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging labors. We intend to send none but worthy men.

J. F. ORSONA—San Francisco.  
A. C. KNOX—Sonoma, Napa, Lake and Mendocino counties.  
J. W. McGRAW—Santa Clara county.  
M. P. OWEN—Santa Cruz County.  
J. W. A. WAIGHT—Merced, Tulare and Kern counties.  
N. E. BOYD—San Bernardino Co.  
JAMES C. HOAG—California.  
B. W. CROWELL—Tehama and Butte counties.  
D. W. KALLANER—Santa Barbara, Ventura and San Luis Obispo counties.  
A. LEONARD MEYER—Utah, Idaho and Montana Ter.

HALL'S VEGETABLE SICILIAN HAIR RENEVER is a scientific combination of some of the most powerful restorative agents in the vegetable kingdom. It restores gray hair to its original color. It makes the scalp white and clean. It cures dandruff and humors, and falling out of the hair. It furnishes the nutritive principle by which the hair is nourished and supported. It makes the hair moist, soft and glossy, and is unsurpassed as a hair dressing. It is the most economical preparation ever offered to the public, as its effects remain a long time, making only an occasional application necessary. It is recommended and used by eminent medical men, and officially endorsed by the State Assayer of Massachusetts. The popularity of Hall's Hair Renever has increased with the test of many years, both in this country and in foreign lands, and it is now known and used in all the civilized countries of the world.

FOR SALE BY ALL DEALERS.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

The State Mining Bureau, No. 313 Pine street, is open to the public from 10 o'clock A. M., to 5 o'clock P. M., daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

DIVIDEND NOTICE.

OFFICE OF THE  
Silver King Mining Company,  
SAN FRANCISCO, APRIL 7, 1881.

At a meeting of the Board of Directors of the above named Company, held this day, a Dividend (No. 10) of Twenty-five (25) Cents per share was declared, payable on FRIDAY, April 15th, 1881, at the office of the Company, Room 19, No. 328 Montgomery street, San Francisco, Cal. Transfer books will be closed on April 11, 1881.

JOSEPH NASH, Secretary.

DIVIDEND NOTICE.

OFFICE OF THE  
Eureka Consolidated Mining Company.

Nevada Block, Room No. 37, San Francisco, April Fifteenth (15), 1881. At a meeting of the Board of the Directors of the above named Company, held this day, a Dividend, No. Sixty-six (66) of Fifty (50) Cents per share was declared, payable on Wednesday, April Twentieth (20), 1881. Transfer books closed until the Twenty-First (21) instant.

P. JACOBUS, Sec'y pro. tem.

REGULAR DIVIDEND NOTICE.

OFFICE OF  
Northern Belle Mill and Mining Company.

SAN FRANCISCO, CAL., APRIL 9TH, 1881.  
At a meeting of the Board of Directors of the above-named Company, held this day, a Dividend (No. 42), of Fifty (50) Cents per share, was declared, payable on FRIDAY, April 15, 1881. Transfer books closed on Monday, April 11, 1881, at 3 o'clock, P. M.

WM. WILLIS, Secretary.

Office—Room No. 29 Nevada Block, No. 309 Montgomery street, San Francisco, Cal.

EXTRA DIVIDEND NOTICE.

OFFICE OF  
Northern Belle Mill and Mining Company.

SAN FRANCISCO, CAL., APRIL 9, 1881.  
At a meeting of the Board of Directors of the above-named Company, held this day, an Extra Dividend (No. 43), of Twenty-five (25) Cents per share, was declared, payable on FRIDAY, April 15, 1881. Transfer books closed on Monday, April 11, 1881, at 3 o'clock P. M.

WM. WILLIS, Secretary.

Office—Room No. 29, Nevada Block, No. 309 Montgomery street, San Francisco, Cal.

Lewis Consolidated Silver Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Pioneer Mining District, Pinal County, Arizona.

Notice is hereby given, that at a meeting of the Board of Directors, held on the Twenty-third (23) day of March, 1881, an assessment, No. Four (4) of Six (6) Cents per share was levied upon the capital stock of the Corporation, payable immediately, in U. S. Gold Coin, to the Secretary, at the office of the Company, No. 310 Pine Street, Room 15, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the Second (2) day of May, 1881, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the Twenty-third day of May, 1881, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

J. W. PEW, Sec'y.

Office, No. 310 Pine Street, Room 15, San Francisco, Cal.

INCERSOLL

ECLIPSE ROCK DRILLS.

The Most Economical Air Compressors in the Market.

MINERS' HORSE-POWER.

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The Power is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to hot timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX,  
49 Fremont St., S. F.

BUY LAND

Where you can get a crop every year; where you will make something every season; where you are sure of having a crop when prices are high; where you have a healthy place to live; where you can raise semi-tropical as well as other fruits; where you can raise a diversity of grain and vegetables and get a good price for them. Go and see the old Reading Grant (in the upper Sacramento Valley), and you will find such land for sale in sub-divisions to suit purchasers—at reasonable rates and on easy terms. Send stamp for map and circular to EDWARD FRISBIE, proprietor, (on the Grant), Anderson, Shasta Co., Cal.

DUNHAM, CARRIGAN & CO.,

LIGHTNING SCREW PLATES

WITH TAPS, DIES AND COLLETS COMPLETE.

B, Stock 23 inches long, 7 Taps and Dies Cuts  $\frac{1}{4}$  to  $\frac{3}{4}$  inch.  
C, " 26 " " 7 " " "  $\frac{3}{8}$  to 1 "  
D, " 53 " " 6 " " "  $\frac{1}{2}$  to  $1\frac{1}{2}$  "

No. 10. Lightning Hand Bolt Cutters and Tappers.

ESPECIALLY FOR CROOKED WORK!

Made to be holted to the Bench or Table. Fitted with seven sizes, from  $\frac{1}{4}$  to  $\frac{3}{4}$  inch. Usual assortment,  $\frac{1}{4}$ , 5-16,  $\frac{3}{8}$ , 7-16,  $\frac{1}{2}$ ,  $\frac{5}{8}$ ,  $\frac{3}{4}$  inch.

SEND FOR CIRCULARS, COMPLETE.

Nos. 107, 109 & 111 Front Street, San Francisco.

HUNTINGTON'S  
Oscillating Stamp Mill

It has no Stems, Cams, or Tappets, and Adjusts itself to the Wear of the Shoes and Dies.

For Simplicity, Economy, Durability and Effective Working, it exceeds anything ever presented to the public, and will do the work of five stamps with one-fourth the power.

Price, 900-Pound Hammer, - - - \$500.

SHOULE MACHINES AND SAW MILL MACHINERY, STEAM ENGINES, ETC., TO ORDER. MINING MACHINERY OF ALL KINDS.

F. A. HUNTINGTON,  
220 Fremont Street, San Francisco.

N. W. SPAULDING'S

PATENT DETACHABLE TOOTH SAWS,

Manufactory, 17 & 19 Fremont St., S. F.

A NEW TREATMENT

Consumption, Asthma, Bronchitis, Dyspepsia, Catarrh, Headache, Neuralgia, Debility, Rheumatism, And all CHRONIC and NERVOUS DISEASES.

PACKAGE CONVENIENTLY SENT BY EXPRESS, READY FOR USE

AT HOME.

A Treatise on Compound Oxygen, giving the history of this new discovery, and a large record of most remarkable cures, will be mailed free to all who ask for it. Also, "Health and Life," a quarterly journal, containing much interesting information. Write for it. Address the proprietors, DR. STARKEY & PALEN, 1109 and 1111 Girard street, Philadelphia, Pa., or H. E. MATHEWS, 606 Montgomery street, San Francisco, Cal., from whom can be procured both information and supplies.

Mining & Scientific Press  
Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice free. Address, DEWEY & CO., Office MINING AND SCIENTIFIC PRESS, 202 Sansome Street, S. F.—1881.

AN ASSAYER and CHEMIST

Who acquired his knowledge at first-class Universities of Europe desires a position. The same is supplied with a complete outfit. Please address, A. B., this office.

## Iron and Machine Works.

### SACRAMENTO BOILER WORKS,

214 &amp; 216 BEALE St. (rear of Etna Foundry).

J. V. HALL,

PRACTICAL BOILER MAKER.

Marine, Stationary and Portable Boilers, Smoke Stacks  
Hydraulic Pipe, Oil or Water Tanks, Ore and  
Water Buckets, Gasometers, Girders,  
Bridges and Iron Ship Building.

### ALL KINDS OF SHEET IRON WORK,

Repairing promptly attended to at the lowest  
possible terms.

### UNION IRON WORKS,

SACRAMENTO, CAL.

ROOT, NEILSON &amp; CO.,

MANUFACTURERS OF

### STEAM ENGINES, BOILERS AND ALL

Kinds of Machinery for Mining Purposes.

Flouring Mills, Saw Mills and Quartz Mills Machinery  
constructed, fitted up and repaired.

Front Street, Between N and O Streets,  
SACRAMENTO, CAL.

### Golden State & Miners Iron Works,

Manufacture Iron Castings and Machinery  
of all kinds at Greatly Reduced Rates

STEVENSON'S PATENT

Mold-Board AMALGAMATORS,

Golden State Pressure Blowers.

First St., between Howard &amp; Folsom, S. F.

### California Brass Foundry,

No. 125 First Street, Opposite Minna.

SAN FRANCISCO, CAL.

All kinds of Brass, Composition, Zinc, and Babbitt  
Metal Castings, Brass Ship Work of all kinds, Spikes,  
sheathing Nails, Rudder Braces, Hinges, Ship and Steam-  
boat Bells and Gongs of superior tone. All kinds of Cocks  
and Valves, Hydraulic Pipes and Nozzles, and Hose Coup-  
plings and Connections of all sizes and patterns, furnished  
with dispatch. PRICES MODERATE.  
J. H. WEED. V. KINOWELL.

### California Machine Works,

WM. H. BIRCH, Prop'r.

119 Beale Street, San Francisco.

General Mechanical Engineer and Machinist.  
Steam Engines, Flour, Quartz and Mining Machinery.  
Sole manufacturer of Brodie's Patent Rock Crushers and  
Steel Faced Tapirs. Agent and Manufacturer of F.  
A. Young's Patent Steam Packing Rings for Steam Pistons.  
The best ever invented; can be applied to any Engine  
Piston and give entire satisfaction to those using. Steam,  
Hydraulic and Sidewalk Elevators. Repairing promptly at-  
tended to.

### STEAM ENGINES AND BOILERS

Of all sizes—from 2 to 60-Horse power. Also, Quartz  
Mills, Mining Pumps, Hoisting Machinery, Shafting, Iron  
works, etc. For sale at the lowest prices by

J. HENDY, 49 and 51 Fremont Street, S. F.

### Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with  
Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when ad-  
visable.

STEAM LAUNCHES, Barges and Steam Tugs con-  
structed with reference to the Trade in which they are  
to be employed. Speed, tonnage and draft of water  
guaranteed.

STEAM BOILERS. Particular attention given to  
the quality of the material and workmanship, and none  
but first-class work produced.

SUGAR MILLS and SUGAR-MAKING  
MACHINERY made after the most approved plans.  
Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size  
made in suitable lengths for connecting together,  
sheets rolled, punched, and packed for shipment ready  
to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and  
Water Pipe made by this establishment, riveted by  
Hydraulic Riveting Machinery, that quality of work  
being far superior to hand work.

SHIP WORK. Ship and Steam Capstans, Steam  
Winches, Air and Circulating Pumps, made after the  
most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City  
Water Works purposes, built with the celebrated Day  
Valve Motion, superior to any other Pump.

## \$1,000 CHALLENGE!

### THE FRUE ORE CONCENTRATOR.

Over 250 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.  
Saves from 50 to 100 per cent. more than any other Concentrator in use, and the concentrations are clean from the first working.

The wear and tear are merely nominal; the water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to six or ten machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of \$1,000 each, and we mean business.

## The O'Harra Chloridizing Furnace.

We illustrate on this page the O'Harra chloridizing furnace, a metallurgical appliance, now for some time in use on this coast, and which has given satisfaction, judging by the testimonials of those who have used it. The furnace costs from \$4,500 to \$6,000 according to size of from 40 to 60 tons capacity per day. We have prepared the following very complete description of the furnace in detail, and with the aid of the engravings, the construction and operation can be readily understood.

This furnace is constructed of the usual materials, and is made with two separate hearths, one for desulphurizing and the other for chloridizing the ore, both processes being performed at the one operation. The lower hearth is a perfect plane, and is separated from the upper hearth, also a plane, by the longitudinal diaphragm, or division, which forms the roof of the lower furnace and the floor of the upper one.

At the end of the furnace, where the ore is fed and discharged, is a grooved pulley, mounted on a shaft, to which power may be applied, as shown. At the other end of the furnace is built an extension or frame-work, at the outer end of which is another pulley. Around these pulleys passes an endless chain, which passes completely through the furnace, going one way through the upper compartment and the other way through the lower as the grooved pulley is rotated on its shaft by the steam engine.

The pulleys carrying the endless chain move from left to right, so that the scrapers or conveyers on the chain move over the upper hearth from the opening through which the ore is fed, and then back through the lower compartment, thus admitting of the ore being fed and discharged at the same end of the furnace.

Attached to this endless chain, at proper distances apart, are conveyers or scrapers, formed into a triangular shape. To the front bars of this triangle are fastened a number of hoes or stirrers, at such an angle that they will push the ore on the hearths from the center to the sides. On the next triangular scraper the hoes are set in an opposite direction, that they will scrape the ore from the outer part of the hearth to the center.

The hoes or plates in each alternate scraper are set at opposite angles, so that one set of plates covers up the furrows made by the previous set, thus keeping the ore continually stirred, so that all portions are subjected to the action of the heat and the chloridizing substances, and so that it may be thoroughly desulphurized and chloridized as it passes through the furnace. As each scraper with its set of plates or hoes passes through, it moves the ore ahead, somewhat at the same time that it stirs it over.

In the center of the extension frame, between the center portions of the frame work, are the pulleys or sheaves which take the weight of the endless chain as it passes out of the furnace. On the outer ends of the two shafts carrying the pulleys on which the endless chain revolves, are two pulleys, over which the scrapers carrying the plates pass. The peculiar triangular shape of these scrapers or conveyers admit of their passing over the pulleys without difficulty.

In the center of both upper and lower hearth is a longitudinal groove, into which the endless chain may be dropped when the machinery of the furnace is stopped. In order to accomplish this, the shaft carrying the pulley on the extension is mounted on a carriage which admits of a forward and backward motion.

When the furnace is in operation, the carriage carrying the shaft on which the pulley is mounted, is slid to the outer end of the frame or extension and secured so as to tighten the chain. As the chain then passes in and out of the furnace in its rotation it becomes alternately heated and cooled, and it is not injured by the heat and sulphurous fumes.

When, however, the machinery is stopped while the furnace is still hot, that part of the chain within the furnace would be injured by the action of the heat and gases. By sliding the carriage carrying the shaft and pulley back toward the furnace the chain is slackened and

drops into the grooves in the hearth out of the way. At either end of both upper and lower hearths is hinged a door, having a groove at its lower edge, through which the chain passes. As each conveyer comes to the door it pushes the door up on its hinges out of the way, and when it has passed in the door drops to its seat again, the groove in the bottom allowing the chain to pass on. This door is intended to prevent there being too much open space at the

with its natural tendency to rise, will pass on up into the upper compartment. As soon as this upper compartment is thoroughly heated, the fire-clay damper is pushed in and the fire stopped. The heat from the fire will then pass over the bridge-wall to the lower hearth. After the upper part of the furnace is once heated, or starting up in the manner described, the heat from all the fires is then directed into the lower compartment first, passing up through the open-

SIDE ELEVATION OF O'HARRA FURNACE.

ends of the compartments, which would affect the draft.

The ore is fed into the hopper and drops into the upper hearth. The action of the plate on the conveyers, actuated by the endless chain, gradually carries the ore along this hearth to the other end of the furnace until it reaches this opening, when it falls through the opening into the lower hearth. Here the conveyers having passed over the pulley on the extension, are carried by the end-

ing to the upper compartment, and thence to the stack.

At each of the fire-places, just under the grates and between them and the ash-floor in the sides of the furnace are a number of small openings, passing through the bridge-wall that separates the fire-places from the hearths. These openings thus connect with the lower compartment and admit a large supply of oxygen to the flame of the fire as it passes from the fire-place over the bridge-wall, thus allowing all the carbon to

PLAN OF THE O'HARRA FURNACE.

less chain back over the lower hearth to the end of the furnace, where the ore was fed, and by the same action previously described, carry the ore with them.

On the lower hearth, at the front end, is formed another opening, similar to the opening on the upper hearth. The ore is carried along the lower hearth by the action of the conveyers or plates until it reaches the opening, when it drops through the opening into the chamber, from which it may be removed when cooled.

he consumed and giving a better oxidizing flame than could be furnished by other means.

On both sides of the furnace at intervals, are a number of openings into the upper and lower compartments, through which air may be admitted. These openings have doors so arranged as to regulate the size of the opening, so as to admit more or less air or to close the openings entirely if desired. The object of these openings is to admit an additional supply of oxygen to the ore to bring about the chemical changes

END VIEW OF O'HARRA CHLORIDIZING FURNACE.

If considered necessary, the lower hearth may be extended and this opening closed, and the same mechanical means may move the ore along the extension of the hearth in the open air and discharge it perfectly cooled. Four or more fire-places are provided to the furnace, two on each side, and two of them so arranged that the heat may be directed to either the upper or lower compartment, and the other two to discharge the heat to the lower compartment alone, whence it will find its way by means of the opening in the upper hearth to the upper compartment, and thence to the stack. On two of the firing places are placed flues which are connected with the upper compartment, by drawing out the damper. The flame and heat,

necessary to desulphurize the ore. The supply of oxygen thus admitted also tends to increase the heat, so that the furnace consumes its own smoke, and no heat is lost.

On the arch of the upper compartment of the furnace are formed a series of jogs or projections which act as bafflers or obstructions, which intercept the flying particles of ore carried onward by the draft, and precipitate them to the hearth, where they are again mixed with the ore. By this means no particles of ore are carried out by the draft to the stack, for as they fall to the floor from the projections or jogs, the action of the conveyers and plates carries them along with the ore to the discharge opening as before described. The space be-

tween the roof and hearth of each compartment is quite small, so as to confine the heat close to the ore.

The operation of this furnace is as follows: The ore is fed continuously from the battery into the hopper, through which it falls onto the upper hearth. The conveyers and plates or hoes, actuated by the endless chain, as previously described stir the ore on the hearth over and over, keep it from caking or clogging, and gradually push it along over the hearth to the opening, where it falls through to the lower hearth. As the ore is passed along in the upper compartment, it is thoroughly desulphurized by the heat furnished by the fires as described, and by the combustion of the sulphur in the ore. This action is assisted by the oxygen in the supply of air admitted at intervals through the sides of the compartment by means of the openings. For a chloridizing roasting, salt is mixed with the ore as it is fed into the hopper and becomes thoroughly intermingled with it by the stirring action of the plates or hoes. If there is any free silver in the ore, it gets the benefit of the chlorine vapors passing up from the lower hearth.

Now, when the ore falls through the opening and onto the lower hearth, the fall will break up spongy lumps or masses that may have formed, and the ore is again stirred over and over, and carried slowly along through the flame and heat over the lower hearth by the action of the conveyers and plates toward the discharge opening. As the ore is moved along in contact with the fires opening into the lower compartment, the salt gives up its chlorine by the action of the sulphurous gases rising from the decomposing metallic sulphates which have been generated, which action converts the metallic sulphate into chlorides with the simultaneous production of sulphate of soda.

The process is essentially the same as the well-known Freiberg process; but the mechanical devices applied to the furnace and the peculiarity of its construction enable the inventor to thoroughly desulphurize and chloridize the ore to a higher percentage than other furnaces, and with less cost for fuel and labor. When the desulphurization has been accomplished and sulphuric acid ceases to be formed, with the old method, it has been necessary to increase the fires to complete the finishing calcination by decomposing the salt, so that the chlorine evolved will transform the metallic sulphates into chlorides.

By this method, no increase of fires is necessary. The construction of the furnace is such that the heat is greatest just where it is needed—viz., at the point where the ore has been desulphurized—and when it is ready to receive the chlorine from the decomposing salt, in order to be thoroughly chloridized.

The ore, while on the upper hearth, is freed from its sulphur by the combustion of that substance by the heat afforded by the fires, and the combustion of the sulphur is assisted by the supply of oxygen admitted through the side openings, as described, which supply may be regulated so as to suit a class of ore more or less highly sulphureted. During all this time a certain amount of chlorine vapor is rising from the lower compartment and assisting in transforming any metallic silver into a chloride.

By the time the ore drops onto the lower hearth the metals have become sulphates, and here more heat is required, in order that these sulphates may decompose the salt, by the sulphur being liberated and uniting with the oxygen and hydrogen, forming sulphuric acid, which unites with the sodium and forms sulphate of soda, while the chlorine is set free and converts the metals into chlorides. The ore has become gradually more and more heated in its passage through the upper hearth, and by the time the extra heat is required, as stated, it comes immediately in front of the same fires which have during the whole process furnished the heat. As the ore passes along the lower hearth it reaches the last fire, where the intense heat will effectually cause the chemical changes described to occur, and the ore is dropped from the furnace thoroughly sulphurized and chloridized, having been stirred over and over in its passage through by the hoes, so that every particle of ore has been subjected to the action of the heat and chlorine vapors.

Ordinarily the ore will be from five to ten  
(CONTINUED ON PAGE 284.)

## Copper Smelting—Its History and Processes.—No. 3.

[By HENRY HOSSEY VIVIAN, M. P.]

This only conclusion I could draw from what I saw at Rio Tinto was, that they must have had numerous small furnaces similar to those Eastern furnaces I have been describing, contiguous to the shafts or levels from whence the ores were raised, because the slags cover the deposit for acres in extent, and show no signs of having been driven from any one central spot, so far, that is, as my limited means of observation went. I conclude that they must have used very low blast furnaces, somewhat like the "Castilian furnace" of the present day, or possibly like the "Scotch hearth" of Northumberland, which is still extensively used for smelting lead ore, and which is little more than an ordinary blacksmith's hearth; such a furnace would probably be less likely than any other form of blast furnace to produce "Eisensamen," or "metallic pigs." It is also probable that they

Roasted the Ore and Regulus in Heaps. Because the Spaniards do so at the present day, and have done so from time immemorial, for the purpose of rendering a portion of the copper soluble, and thus obtaining it by lixiviation and subsequent precipitation by iron. It is by this process that the present great copper production of Rio Tinto, Tharsis, and Mason & Co. is effected; but in Roman times, it is plain that the rich ores alone were worked, and that the copper was obtained by smelting; otherwise, the enormous masses of slags which we see could have had no existence. I am confirmed in this belief as to Roman copper smelting by the process adopted at the Ocker Hütte, in the Hartz mountains, where ore of a similar character to Spanish pyrites is produced from the great Rammelsburg mine, which is said to have been continuously worked from times quite as remote as the Roman era. That ore is a pyrite rich in iron and sulphur, but poor in copper. It is, or was up to a recent date, hurled in heaps, and then smelted in low blast furnaces, so low that the ore is charged from the floor of the works, no stage being used, as is usually the case in blast furnaces; the resulting regulus is, or was, burnt again and again in heaps, and again and again melted in low furnaces. I believe little or no change took place in the process of copper smelting at the Ocker Hütte from the remotest times up to the date of which I am speaking, some 35 years ago, and that we have there a relic of the practice of those bygone ages; by no means a bad one for the class of ores and fuel they had to deal with.

No doubt the Romans obtained their

### Supplies of Copper

From various sources besides Spain. There appears to be little evidence as to the working of copper mines by the Romans in England. Dr. Percy, however, quotes M. Albert Way and Mr. Franks, two eminent archaeologists, as having informed him that lumps of metallic copper, more or less rounded, have been discovered in different parts of the country, but always in association with articles of bronze. He examined one of these, and found it to be practically pure copper. He also says that Pennant describes a cake of copper found at Caernarvon, or Caer-hen, the ancient "Conovium," near Conway; it weighed 42 lbs., and resembled a cake of beeswax; the diameter at the widest part was 11 inches, and the thickness 2½ inches. On the upper surface was a deep concave impression, with the words "Socio Romæ," and across them the word "Natsol." This would seem to indicate that a Roman co-partnership existed, and that the partners received their dividends in kind. Dr. Percy supposes that the copper came from ores raised at Llandudno, which were smelted *in situ*. This, I believe, is almost a solitary instance of Roman copper in England, although they had abundance of bronze; but whether imported or produced here, we know not.

What happened in the dark period which followed the withdrawal of the Romans from Britain, I am unable to say, nor do I believe that any authentic record exists. We must remember the condition of England at that time. Hume thus describes it: "The private and public edifices of the Britons were reduced to ashes; the priests (Christian priests) were slaughtered on the altars by those idolatrous ravagers; the bishops and nobility shared the fate of the vulgar; the people, flying to the mountains and deserts, were intercepted and butchered in heaps; some were glad to accept of life and servitude under their victors; others, deserting their native country, took shelter in the province of Armorica, where, being charitably received by a people of the same language and manners, they settled in great numbers, and gave the country the name of Brittany." Hume quotes from Bede, Usher and Gildas to support his assertions. We must remember that the period which succeeded the withdrawal of the Romans was one of almost constant warfare. It is not until the time of Elizabeth that I can give any reliable account of what took place in England so far as copper is concerned. Dr. Percy mentions that Edward III., in the 15th year of his reign, granted the right of working the copper mines of Skildane, in Northumberland, and the copper mines of Alston Moor, in Cumberland, and the copper mine near Richmond, in Yorkshire, on payment of a royalty of one-eighth to himself, and one-ninth to the lord of the soil, to a company of adventurers, among whom was his brother Richard, Duke of Gloucester, and Henry, Earl of Northumberland. In the reign

of Elizabeth, there was a rich copper mine at Keswick, in Cumberland, of which that queen deprived the Duke of Northumberland on the ground that it was a mine royal. It was reported that 4,000 men were employed at that mine, but this is probably a great exaggeration. According to Camden, much good copper continued for a long time to be made at Keswick and Nawland; but Webster, in 1671, wrote that now "the work is quite left and decayed, yet I am informed that some do now melt forth as much good copper as serveth them to make half-pennies and farthings." I beg especially to direct your attention to this smelting at Keswick, in Cumberland, because I think there is no doubt from the records brought to light by the laborious and intelligent researches of our fellow-townsmen, Lieut.-Col. G. Grant Francis, that the first smelting works in South Wales was built and worked by men from Keswick. I am very glad indeed to hear testimony to the great interest and value which attaches to Col. Francis's work, of which I am about to avail myself to give you a short account of how copper smelting began in this district. I allude, of course, to the work published by Col. Francis in 1867.\* It is not my purpose to give the history of copper smelting down to the present day; those who desire to go into the details of that history will find them fully set forth in Col. Francis's admirable work; but what I desire to do is, so far as I am able, to trace the history of the process known as the South Welsh process of copper smelting, which really now is the dominant process of the world. I remember well that Col. Francis announced to me before he published his letters in 1867, that he had discovered that our Welsh copper smelting

### Process Came from Germany.

I at once told him, and I still retain that opinion, that such could not be the case, inasmuch as nothing analogous to it existed in any part of Germany even down to our time. I think we were both in part right. The evidence Col. Francis has discovered puts it beyond a doubt that Germans were largely engaged in the Keswick smelting; but there is no title of evidence that I can discover that they brought our reverberatory process with them from Germany. In point of date, the story begins with a patent granted by Queen Elizabeth, in 1564 (page 29), to Thomas Thurland, Jr., of the Savoy, and Daniell Hogstetter, a German, giving them "power and authority to search, dig, try, roast and melt all manner of mines and ores of gold, silver, copper and quicksilver in York, Lancaster, Cumberland, Westmoreland, Cornwall, Devon, Gloucester and Worcester, and the principalities of Wales, as well within her Majesty's own grounds as others, on payment of a royalty." In the same year, a patent was granted "to William Humphrey, and Christopher Shutes, a German, with similar powers within England, and the English pale in Ireland, except the places afore granted." Under the first of these patents, no doubt, the working and smelting at Keswick was carried on. Seventeen years later, in 1581, we find a letter from Mr. George Nedham, to Sir Francis Walsingham, setting forth in considerable detail the operations which were carried on under the direction of one Jochim Gause, Ganse, or Gans, for his name is spelt in these three ways. This letter is of a most interesting character, and contains, I believe, distinct indications of the

### First Introduction of the System

Of copper smelting which has been ever since that date so largely practiced in this district, and which is now more or less adopted in almost every important copper-producing district of the world. I gather from this letter that the Keswick Works were managed by Mr. Daniell (possibly the Mr. Daniell referred to was Mr. Daniell Hogstetter) and Mr. Stemberger up to 1581, when Mr. Jochim Gans went there; that their practice had been to roast and smelt the ore and regulus repeatedly; as many as 16 and even 22 fires are mentioned; half of these were roastings and half meltings, and the time occupied was as many weeks as fires. It is pretty certain that the roasting was done in heaps; for by no means can I conceive it possible to roast and melt so many times without producing copper. Nedham says (Par. 3, page 20): "And further, the said Jochim doubteth not but after he hath roasted and smolten 3, or 4 saies of o'r copper ure in the great worke, after such manner as he hath devised since his coming from Keswick, to attaine to such further knowledge of the nature of all o'r coppse ures in Cumberland and Westmoreland, that he shall be able to kill all corrupt humours in them and thereby to bring out more copper than heretofore hath byn and with lesser charge than is above written."

\*"The Smelting of Copper in the Swansea District, from the Time of Elizabeth to the Present Day." By Major Grant Francis. Not published. 1867. 8vo, 120 pages. (Only 50 copies printed.) For announcement of the Second Edition, see *Engineering and Mining Journal*, February 5, 1881, p. 95.

(To Be Continued.)

THE TUCSON, A. T., *Citizen* says that the antimony mines are the boom of Sonora. Ore of that kind in such quantities has not been recorded in the known world. About 300 tons taken from a shaft 70 ft. in depth on the Santa Margarita contains over 70% antimony and at least \$200 per ton silver.

THE March product of the Deadwood-Terra mine is given at \$75,000, and of the Homestake \$103,000.

COPPER CITY, Shasta county, has shipped \$6,326 since April 1st.

## The Cost of Amalgamating Ores in Utah and Nevada.—No. 1.

[Read before the American Institute of Mining Engineers by R. P. ROTHWELL, M. E., New York City.]

The milling of silver ores has arrived at a great degree of perfection in the mining districts of our Western States and Territories; and I have thought the record of the practical results obtained at the present time, in a few of the principal districts, would prove of value and interest to many of our members, both at home and abroad.

1. An American silver mill is composed, in descending order from where the ore is dumped, of a rock breaker, usually of the Blake or Alden pattern; 2. The battery of stamps, the number of which varies from 5 to 120, generally in batteries of 5 or 10 heads, so arranged that a single battery may stand while the others are running; 3. The tanks where the crushed ore settles (if it be a wet stamping mill), or of a drying floor if the crushing be done dry; 4. Amalgamating pans; 5. Settling pans; 6. Agitators or pans in which mercury escaping in the tailings is caught; 7. Blanket sluices, over which the tailings run, and where mercury and unamalgamated sulphides are saved.

### The Ontario, Utah, Silver Mill.

One of the best examples of a silver mill, and at the same time one of the most successful concerns in the West, is the mill of the Ontario Silver mining company, near Salt Lake, in Utah. This mill treats the ore from the Ontario mine, ore which at present is very base, being composed of zinc, lead and silver sulphides and silver chloride in a quartz gangue. This ore has become baser as the mine attained greater depth, though the vein holds its own, or rather increases, both in thickness and richness. The mill is managed in a skillful and economical manner, though the necessity for roasting the pulverized ores in Stetefeldt furnaces necessarily makes the cost of milling much greater than in the case of such free milling ores as those of the Comstock mines, and especially than those unrivaled free milling ores of the silver-bearing sandstone district of Silver Reef, in southern Utah.

I will here summarize briefly the various operations through which the ore goes in the Ontario mill, giving at the same time the number of men employed in each part of the work, and the wages they receive, as well as the quantity of chemicals used. For this data I am indebted to the courtesy of the very efficient general manager of the Ontario company, Mr. J. C. Chambers, and to the skillful young superintendent of the Ontario mill, Mr. J. E. Gallagher.

The mill is charged with the hauling of the ore from the mine to the mill, which costs by contract 50 cents per ton dry. The moisture averages about 11%. The distance is about a mile, and down grade all the way, four-horse teams hauling six to seven tons at a load. The ore, which is weighed by one weigher at \$4 a day, is delivered on the ore floor screened, by passing over iron bars 2" x 3" x 9' long, with spaces of two inches between; the inclination of the bars is about 30°. The coarse ore goes through two Blake crushers, attended by one man at \$2.50 per day, and is crushed to the size of a pigeon's egg, and then goes along with the fine ore which has passed between the screen bars through shoots to the drying floor, which is heated by 13 flues, seven of which are heated by auxiliary fires and six by the waste gases from the Stetefeldt furnaces and one auxiliary fire. It was at first supposed that the waste gases from these roasting furnaces would have sufficed for the drying floor, but experience has shown that they do not. From the shoot the ore is carried over the drying floor in cars, which carry 1,000 lbs. of ore (dry), and from this measure the quantity of salt is gauged. The ore is spread over the floor to a depth of three inches, and, after drying for two hours, 1½% wet (about 15% dry) of salt is scattered over the ore. The salt used is evaporated from the waters of Salt Lake, and costs at the Ontario mill about \$7 per ton, \$5.50 of this being for hauling from the salines to the mill. The ore is left from one and a half to two hours after the addition of the salt for the purpose of drying the same, and is then turned with shovels. This work is very injurious to the men, who quickly get swelling of the legs, it is supposed from arsenic in the ore, and in this, as in most other trying occupations, it is found that indulgence in alcoholic stimulants quickly incapacitates the workmen. Three men on a shift and three shifts a day, with wages at \$3.50 per day, are required for the work on the drying floor. After turning, the ore and salt remains on the floor for from one-half to one and a half hours, and is then scraped off by a mechanical scraper to the self-feeder of the battery.

The battery consists of 40 800-lb. stamps, which drop 8 to 8½ inches 92 times per minute. The shoes, dies and tappets are of steel, cast in Collinsville, near Hartford, Conn. The dies and shoes wear from two to six and sometimes eight months; the tappets and cams last 12 months. The cams weigh about 250 lbs., and the iron stamp stems are 3½ inches diameter and 14 ft. long. The stamp screens are of brass wire, No. 30, that is, 900 meshes in a square inch. Formerly a No. 50 screen was used, but as the ore became more base it would not splash high enough on the screen, and the amount it was possible to mill dry became greatly reduced. Mr. Gallagher tried the larger mesh screens with great success, it being found that the roasting and chlorination in the Stetefeldt furnaces

is quite as perfect, if not more so, on the coarse ore as on the fine. The battery requires the attendance of one man each shift; wages \$4, and three shifts a day. This crushed ore is conveyed from the battery by a screw shaft, working in a box parallel with the battery to a common flour-mill elevator, (with Russia-iron cups 22 inches apart, on a rubber belt 6 inches wide, and which lasts two years). This raises it to a vertical height of about 50 ft., to the pockets over the Stetefeldt furnaces; thence it passes through two screens, the bottom one of which is fixed, and stands on the top of the water-jacket, and the upper one vibrates, making about 50 strokes per minute. It is run by cone pulleys, and over the vibratory screen are four brass bars called "agitators," which keep the ore moving on the screen. The screens are of No. 18 steel plate, punched with 10 holes to the inch, and the ore sifts down through them into the furnace. This is 46" 6" high, and from the bottom the ore is drawn every three-quarters of an hour. One man on a shift (wages \$4), and three shifts a day, is all the labor required at the screens. This man takes samples for assay every hour.

(To Be Continued.)

## Railside Horticulture.

The Central and Southern Pacific railways have done a good thing for the State by their system of tree planting beside their tracks. We have been pleased also to see here and there a switch-tender so imbued with the love of the beautiful that he has embowered his little cabin with a fine growth of vines and surrounded it with miniature flower beds. There is also a disposition in some towns to beautify the surroundings of the railway stations. The Dwight-way station, in Berkeley, is enclosed in a pretty little park, arranged under the auspices of the Berkeley Neighborhood Improvement Society. There is room for much more good work of this kind all over the State, for many stations are unsightly places; as inhospitable and bare as neglect can make them. This is exceedingly unfortunate, for many reasons, and should be changed. First impressions are very strong with many persons and if one is met at the station, when descending from the car steps, with a view of desolation and unthrift, it may take many miles of flower gardens afterward to win a good opinion of the town. If the stations were made over into little oases of shrubs and trees the effect would be quite different. Each village and town should have a pride in a work of this kind. It would be comparatively easy if the people would interest themselves in it. We are of the opinion that the railway company would furnish most of the trees and shrubs, and then all that the people need do is to see that they are kept in condition fit for growth. There is no telling how wide reaching the influence of such improvements might be. It is quite possible that the picnic character of the surroundings would impel the station loafers to indulge in an occasional clean shirt, and the agent might tread the platform with polished boots. Even such great changes as these are quite within the possibilities.

Railside and station horticulture is not at all a new idea. It is practiced quite generally in the older States and abroad. The *New York Tribune* recently noted facts in this connection, stating that there are some pleasing examples of railway gardening in Maine. In Pennsylvania many of the station areas are brightened by the smiling beauty of flowers and the graces of foliage. In Europe, where there are more people with less to do, and where the shorter lines of roadways of all sorts can be kept on that account, in garden trim, it is common to see every little country station, however lonely and retired, beds of bright flowers edging the walls and shining in the windows. All stations are inclosed there; the gates being opened from the gatekeeper's lodge for every passing vehicle. Here, each planted area has necessarily its own fence, all around being entirely open. The cuttings near Paris are planted all over the slopes with American locusts.

As we have hinted before, California has already some good examples of what we would make prominent. There are also some beautiful spots along the dreary overland route through Nevada. We would have a thousand times as much of it. Which town in California will have the prettiest station? It is time now to plan and next fall to plant.

HORSESHOE BASIN DISTRICT dry placers are 65 miles west of Tucson, A. T., and remarkable results are reported. B. W. Connelley, an old California miner, is one of the prominent men there.

The dividend of the Ontario mining company paid in New York on the 15th, was on the new shares (150,000), and the amount was, therefore, \$75,000.

LOTS OF WATER.—There are 3,468,000 gallons of water flowing from the mouth of the Suto Tunnel every 24 hours. The temperature of this water is 119°.

THE March product of the Ontario mine is officially reported at \$230,238. The dividend paid at New York last Friday was the 66th, and the grand total is \$3,350,000.

RICH copper has been found on the upper Yellowstone river.

# MECHANICAL PROGRESS.

## A Scientific Railway Car.

Mr. P. H. Dudley, a railway inspector, has devised a special apparatus, which he has permanently attached to a railway car, and by which he is enabled to take an automatic diagram of the road over which his car passes. His apparatus is of a most delicate and complicated nature, and the amount and character of work done by it is simply marvelous. A description of it would be wearisome, with its systems of cog, switches, wires, pens, etc., and it would be almost unintelligible, but an idea of its extraordinary work may be gained from the following summary of its accomplishments, as given by the Pittsfield (Mass.), *Sun*:

A band of plain paper, about 20 inches wide, is fed from a roll into the machine, passing under a complex set of overflowing pens. For every 50 ft. of track passed over by the car this paper moves one inch, thereby taking eight and a fraction ft. for a mile of road. By carefully constructed and adjusted machinery, connected with the wheels of the car, the operator obtains upon the paper a perfect chart of every foot, yes, every inch, of the road. The instrument shows: first, the power required to draw the train; second, a pen marks on the paper the seconds of time in transit; third, another pen marks every tenth second in the same way; fourth, still another pen marks each minute. Then comes a schedule showing the distribution of coal used by the engine; the amount of water used by the engine; a perfect diagram of the track is delineated, showing all curves, grades, etc.; the number of revolutions which the driving wheels of the engine make in a minute or mile, or parts of these two; the location of the mile posts are shown, and also the bridges; the work done by the engine, so given that the foot-pounds of work can be readily ascertained by multiplying the ratios; the velocity and resistance of the wind. All these are plainly and accurately shown upon the diagram. When used to inspect the track, the machine shows the surface of each rail, giving the condition of each joint, frog, etc., and shows at a glance whether the rails are fitted perfectly true, or the least trifle out of place, or if one is a hair's breadth higher than another.

The elevation of the rail on a curve is shown, and a machine has just been added, which Mr. Dudley invented, given the exact amount in feet and inches that the rails are depressed from a true line. Another section of the chart gives the exact movements of the engineer when the brakes are applied, when steam is put on, and the power required to start and stop the train. Mr. Dudley examines a road in this way, hands his chart to the superintendent, and that gentleman knows at once just where to make repairs and all other needful particulars. Mr. Dudley spent eight years perfecting his machine, and, save one which he made and sent to Australia, his is the only one in existence.

Besides his work-room there are a nicely furnished library and parlor, containing cabinets and a fine piano, a dining-room, kitchen, bedroom and store-room. All this in a common size passenger coach, and in it Mr. and Mrs. Dudley have lived for the last four years, traveling all over the United States. The lady says the life is a very pleasing one, and she enjoys it much. Both the lady and gentleman are kindly educated and entertaining people, and an hour spent in their company is a very profitable one.

**MECHANICAL QUACKS.**—No trade is so pestered with quacks, hatches and pretenders as that of the carpenter and joiner's. Go where you may, the ubiquitous botch, with his brier-root saw, hattersed jack-plane and defective square, is on hand, ready to undertake the designing and erection of a back fence or State court house. Gifted with a mind that rises above the ordinary concerns of life, he looks with contempt on the man who has "fooled" his time away learning a trade, or who fritters away his employer's substance by making good joints and lasting work. It makes no difference to him what kind of a building you may have to erect, he is always ready, willing and able to do it, and can make the price to suit. Tell him how much money you wish to expend, and the size, style and character of building you want, and you will find him equal to the difficult task of making one fit the other. He is full of promises and will guarantee all kinds of good things if you will only let him have the contract. When the work is completed—according to his idea of completeness—if it stands to be completed, you are astonished, though not charmed, at the "emphasis" of the joints and peculiar, hear-skin like finish of the work. The quarreling, the profanity, the law suits, suicides and murders that follow, are interesting, romantic and delightful in the extreme; but amid all this, the "botch" never loses his equanimity. —*Builder and Woodworker.*

**HARDENING SMALL TOOLS.**—It is said that the engravers and watchmakers of Germany harden their tools in sealing wax. The tool is heated to whiteness and plunged into the wax, withdrawn after an instant and plunged in again, the process being repeated until the steel is too cold to enter the wax. The steel is said to become, after this process, almost as hard as the diamond, and when touched with a little oil or turpentine the tools are excellent for engraving, and also for piercing the hardest metals.

## Why Nuts Work Loose.

Mr. Rose explains that the tendency of a nut to unwind and recede from the pressure upon its radial face is proportionate to the pitch of the thread and the diameter of the bolt; and the finer the thread upon a given diameter of bolt, or the larger the diameter of bolt with a given pitch of thread, the less will be the tendency of the nut to move back. In the case of ordinary bolts and nuts, a given diameter of bolt is given a standard pitch of thread, and these pitches are not so fine as to prevent the nuts from unscrewing in many cases, unless check nuts are used. It would appear that if the nut thread fits reasonably tight upon the bolt, and the nut is screwed well home, it would remain there; but there are palpable reasons why it should not do so. Of these the chief are the errors which ensue from the alteration of form which takes place in the screw-cutting tools during the hardening process.

As a rule, all steel increases in dimensions from being hardened. What the amount of increase or expansion is, we have at present no definite knowledge, because it varies considerably, although it is probably the same when the conditions are identical. Suppose, then, that a tap is made of the correct diameter to a vernier gauge, and that it increases in diameter and in length (as it almost invariably does) during the hardening, then the pitch, the thickness, the depth and the diameter of the thread will be altered and "out of true." Unless both the tap and the die are tempered to precisely the same shade or color, the amount of error will vary. As a result of these at present irremediable errors, taps are made to suit existing solid dies, or adjustable dies are set to suit the taps; and though the nut may fit closely to the bolt, so as to be just movable by hand, or under the moderate pressure of a wrench, yet the sides of the thread do not fit properly, nor can they be made to do so under any ordinary conditions. The result is that, under vibration, the threads give way on the contact sides; for vibration is, in effect, a number of minute blows. Under reciprocating motion the result is precisely similar; for the whole pressure upon the nut is supported by that part of the surface of the thread which is in contact, which compresses or rescedes. Any machinist who desires to test this matter may do so by taking a nut that fits very tightly upon a bolt, and striking upon the sides, he will find it will lose the fit to the bolt. —*Iron Manager.*

The reduction of cost in the manufacture of iron and steel during the last 25 years has been truly wonderful, and yet the farthest limit of economy appears to be as far off as it was at the beginning of the period we have mentioned. Indeed, the ladder of progress in this direction, like the ladder Jacob saw in his dream, apparently reaches to the sky. The position already attained has been reached partly by short steps and partly by great strides, but the movement has been steadily onward, one step upward affording vantage ground for another. We are led into these reflections by the announcement of an invention, which, we are reliably informed, effects a great saving of coal in the processes of puddling and heating iron. By this invention the gas which arises from the burning coal in the heating and the puddling furnaces is again brought into service, effecting a saving of 33% on the quantity of coal ordinarily consumed in such furnaces. The invention can be applied without any alteration of the furnaces whatever, and the cost never exceeds \$35 per furnace. Mr. B. C. Lauth, so well known to the iron trade of America and Europe, has formed a company, of which he is general manager, for the manufacture and introduction of this invention. Seventeen have already been put in the Bethlehem Iron Works, and quite a number in other mills in the eastern part of Pennsylvania. —*Am. Manufacturer.*

**SUBSTITUTE FOR PLATED METALS.**—An Englishman has invented an alloy which provides an inexpensive substitute for bell metal, silver or electro-plated metals, used for making ships' fittings, harness fittings, taps and cocks. The alloy is composed of 45 to 60 parts by weight of refined copper, 20 to 30 parts of zinc, 18 to 25 parts of nickel, and if the castings are required to be turned, two or three parts of lead. The proportions can be varied according to the purity of the metals used, and the color or quality of the alloy to be produced. The copper and nickel are first melted together in a crucible, and the temperature is allowed to fall. When the zinc, or zinc and lead are added with a small quantity of potash, soda and borax, the whole is covered with finely powdered charcoal; the temperature is then rapidly raised and the whole well stirred, then skimmed and immediately poured into the molds, or it may be cast into ingots first, in which case a greater percentage of zinc is added to make allowance for waste of the metal in remelting. Articles made from this alloy take a brilliant polish, and in appearance resemble silver or nickel.

**IMPROVED STEAM VALVE.**—Bahcock & Wilcox, of New York city, have recently taken out English patents upon a means of operating valves for steam engines, as well as some improvement in boilers or steam generators. They seem to have combined the Corliss type of valve with a style of link somewhat resembling the Allen, which is in reality a double link.

# SCIENTIFIC PROGRESS.

## A Novel Theory.

It is well known that, connected with all organisms, there are certain gaseous substances (odoriferous substances), which must play a very important part in human economy, but one hitherto quite undefined. Prof. Jaeger, a German chemist of some note, who has been pursuing investigations in this direction, has quite recently advanced a novel theory in regard to the matter. He endeavors to show that the actions of the human mind are largely influenced by these substances, as they are given off in the acts of breathing and perspiring. He divides them into two groups—emanations, or substances of pleasure, and substances of dislike—"lust and unluststoffe." The first are exhaled during a joyful and gleeful state of mind, and he further holds that they produce a similar state of mind, if inhaled by another. Just the reverse is true of the other. Whoever, he says, will take the pains, can discover for himself the effluvia from the body differs as much from the varied conditions of the mind as from that of the body.

During seasons of joy and happiness the odor of perspiration is not generally disagreeable, while during periods of anguish and unpleasant nervous excitement it is always offensive. In an atmosphere charged with the substance of dislike the vitality of the system is lowered and disadvantageously influenced. This, he holds, accounts for the acknowledged fact that in a state of anguish and fear the body is more susceptible to contagious diseases. The inhalation of the substance of pleasure heightens the vital action and improves the power of the body to resist disease. Prof. Jaeger further announces that wool fiber has a natural attraction for substances of pleasure, apart from its natural capacity for absorbing odors generally, while plant fiber favors the absorption of substances of dislike. Woolen garments, the Professor says, even in summer, when evaporation is large, take on only the sour smell due to continued perspiration, and never accumulate to any considerable extent, other offensive odors, while cotton and linen clothing, after long wear assume a marked repulsive smell. If the truth of this theory should be fully established, it could not fail to be of immense value to medical science in devising ways and means to most effectually protect the human system from contagious and other diseases. —*Californian for May.*

## Microscopic Structure of Metals.

Considerable attention has been given of late to the minute structure of minerals and metals, by aid of the microscope. Allusion has already been made to the microscopic study of minerals in these columns. The same method of study has also recently been applied to the structure of metals. J. Vincent Elsdon communicates some interesting information in this direction to *Nature* of February 24th, from which we condense: Notwithstanding the great opacity of metals, it is quite possible to procure, by chemical means, metallic leaves sufficiently thin to be examined with the microscope by transmitted light. Silver leaf, when mounted on a glass slide, and immersed for a short time in a solution of perchloride of iron or potassium cyanide, becomes so reduced in thickness that its structure may be readily examined. A very satisfactory examination of silver leaf may also be made by first converting into a transparent salt by the action of chlorine or iodine. Most of the metals may also be examined by the use of similar means. Such examinations of metals show two general types of structure, one being essentially granular, the other fibrous.

The granular metals, such as tin, present the appearance of exceedingly minute grains, each one being perfectly isolated from its neighbors by still smaller interspaces. The cohesion of such leaves is very slight. The fibrous metals, such as gold and silver, have a very marked structure, and appear to consist of a mass of fine, elongated fibers, matted and interlaced in a manner much resembling mats of hair. This fibrous structure is more marked in silver than in gold. The fibrous structure, is, no doubt, developed by pressure. Their molecules, when forced to spread out, seem to glide over one another in direct lines—such being the lines of least resistance. This peculiar development of fibrous structure, Mr. Elsdon thinks, may serve to illustrate the probable origin of the fibrous structure of the limestones of the Pyrenees, Scotland, and the Tyrol.

**NEW PYRAMIDS DISCOVERED.**—It is announced among the latest reports from Cairo that two pyramids, hitherto unknown to European travelers, have recently been discovered to the north of Memphis and near Saggarah. These pyramids bear evidence that they were constructed by kings of the sixth dynasty. The rooms and passages, so far as they have been explored, are more profusely than any other covered with inscriptions.

**A CURIOUS EXPLOSIVE.**—An alloy of rhodium and lead, lately exhibited before the French Academy of Sciences, has the curious property of exploding on exposure to heat, as in being held before a gas flame. Its composition is one-third rhodium and two-thirds lead, fused together in a crucible, at a high temperature.

## Possible Revelations of the Microscope.

Much speculation and no inconsiderable experimental study has, of late, been devoted to the query, "Can we hope that the microscope will reveal to our vision an atom or molecule?" The highest magnifying power that has yet been obtained is the distinct revelation of the *striae* upon the *amphipleura pullida*, which number 132,000 to the inch. The highest artificial markings which can be resolved, by ordinary microscopic experts, are 90,000 lines to the inch; but Helmholtz, about a year ago announced that he had been able to distinguish Nobert's lines ruled 112,000 to the inch—and yet the same eyes, aided by the same instrument, failed to define the individual atom or molecule. Fasoldt has devised a ruling machine so superior to that employed by Helmholtz, that, with it, he claims that he can rule 10,000,000 of lines to the inch. These lines are ruled so close that no microscope has yet been able to reveal them to the human eye; yet Fasoldt says they must be there, for his machine must make them, and he is now waiting for some instrument powerful enough and some eye keen enough to reveal them.

Prof. Rogers says that the probable limit of the eye's capacity for seeing is about 4,000,000 lines to the inch. It would seem now to be in order that Fasoldt should make a machine, with progressive powers of ruling, to determine the ultimate capacity of the human eye. Whatever that may be, however, it is certain to stop far short of the power to define the ultimate molecule; for Helmholtz asserts that the molecules of water cannot be far from an approximation to 250,000,000 to an inch. Leihg says that "the chemist merely maintains the firm foundation of his science, when he declares the existence of physical atoms and molecules as an incontrovertible truth." Yet, like Fasoldt and his lines, he has never seen them, but just knows they are there. It has been suggested that the improved microscope of the future will have to be constructed with diamond or sapphire lenses—materials possessing greater refractive power than glass, but that even then the molecule will be a hidden mystery, even though Fasoldt's 10,000,000 of lines to the inch should be plainly visible. —*Californian for May.*

**EXPLOSION OF BODIES UNDER ELECTRICAL FORCES.**—Some important investigations in the expansion of materials under the influence of electrical forces have been made public by Prof. Quincke, some of the more important conclusions from which are as follows: Solid and liquid bodies alter in volume when acted upon by electrical forces. This is not the effect of heat. Most bodies expand, but some contract, notably the fatty oils. Gases do not appreciably change their volume. Some bodies take on the change instantaneously, others more gradually. Tubular condensers change simultaneously in length and volume. In some bodies, notably German glass, the change is, in some measure, prolonged after the action of the electrical forces ceases. The change of volume does not result from an electrical compression of the insulating substance. The elasticity of some substances is increased and that of others diminished. The electrical piercing of bodies is due to unequal electrical expansion. Solid and liquid transparent substances become double refracting under the influence of unequal expansion. These investigations have added a long list of experimental data to electrical science.

**THE COMPASS ON IRON SHIPS.**—A method of neutralizing the influence of masses of iron upon magnetic compass needles is said to have been worked out by Capt. Witt, of the *Birmah*, an English iron vessel in the India trade. The ship was provided with both binnacle and standard compass, as usual, both of which varied from one and a half to three points. Capt. Witt tried the experiment of surrounding the compass with a quantity of earth, which he accomplished by hedging the compass deeply in soil placed in a half cask divested of its iron hoops. It is claimed that, in some unexplained manner, this practically reduced the variation to a quantity not greater than it met with in wooden vessels. The validity of the experiment has been vouched for by Capt. Blanche, an adjuster of compasses, who has repeated the experiment, but the statement needs further verification. If the results are as stated, the discovery is a very important one, lessening the dangers of navigation in iron vessels.

**PHOSPHORESCENT ILLUMINATION.**—The property of phosphorescence has attracted much attention during the past year as a means of illumination. Numerous practical applications of it have been suggested, and some, notably Balmains luminous paint, have been introduced in the markets of Europe and America. An important attempt to utilize phosphorescence excited by electricity, as a means of subdividing the electric light, has been made by Dr. Phippsou. He incloses barium sulphide, or some other substance which is rendered phosphorescent by the solar rays, in a Geissler tube, through which he passes a uniform electric current of feeble intensity. He claims to obtain, in this manner, a uniform and agreeable light at a cost below that of gas. It is possible that this clew, followed out, may result in something valuable. The experiment is very suggestive, and the action of the electric current upon phosphorescent substances has been comparatively little studied.

**STEATITE.**—The great value of steatite and soapstone for stove backs has long been known, but it is not many years since it came into vogue as a boiler covering, though now boilers and steam-pipes everywhere are covered with the compound. Mr. L. L. Merrell, who manufactures this, is also patentee and manufacturer of the Universal wire-bound boiler covering, which has no equal as a non-conductor. Mr. Merrell is also a dealer in asbestos and asbestos materials, hair felting, Lowell Felts, steatite mastic roofing, paints, etc. The mastic roofing is very durable, easily kept in repair and can be shipped like oilcloth anywhere. It is a great protection against fire and water. The steatite paint composition is a wood preservative. A visit to Mr. Merrell's factory at 314 Townsend street, in this city, will be of interest to any one who wishes to see how these non-conductors are utilized. His office is at No. 22 California street.

Goodshaw, South Bodie and University. Bechtel will probably remain idle until some arrangement is made about the mill. The Syndicate is still stopping and milling ore. Several tons of ore from the Vortex (which has long been idle) is being run through the Miners' mill, and we understand the average pulp assay is about \$35. Bodie Tunnel is still breathing ore from the Fostoon or No. 20 vein, and vein No. 7 is also yielding some very good ore. The principal owners of the tunnel property are expected here during the week, and it is highly probable that they will make arrangements with the Goodshaw Co. for the erection of a joint mill of some pretensions. The new hoisting engines of the Standard Con. are now in good working order. There is no change to note in either crosscut of the 1000 level, and the face of the east crosscut, 700 level, 113 ft east of the main vertical shaft, is in very hard rock. The slopes are all looking well, some of them still yield very rich ore. Con. Pacific is showing fine silver ore in the north drift from the east crosscut, 600 level. The east crosscut, 600 level of the Jupiter, is in 98 ft, having passed through the hard bar and come into more favorable ground, indicating the proximity of the east Savan vein. The South Bulwer has its new engine in position and will resume sinking about the first proximo. Toga still has a pretty heavy flow of water, but the north drift from the east crosscut and the west crosscut, 682 level, are both being pushed as usual, the former in good ore and the latter in feeders of quartz carrying gold. The shaft of the Boston Con. is down 71 ft below the 300-ft station, with strong indications that the shaft is nearing the east vein. In Bulwer Con. an upraise recently commenced in the Stonewall ledge, south of the shaft, 400 level, is in 2 1/2 ft of ore. The Bodie is looking well throughout and is turning out some very rich ore. Oro is making very satisfactory developments in all directions. Noonday is showing some improvements south, both on the 412 and 512 levels, and all the machinery of the mine and mill is working finely. North Noonday is also improving on the 312 and 412 levels, the slopes from the latter level showing a vein of good ore from 5 to 12 ft wide. The north drift on the main east vein of Concordia is being vigorously pushed, and the vein is large, strong, and looking well. The last shaft is down 575 ft, the bottom still in very hard rock, with no signs of water, and it is now hoped that water will not interfere until the 600 ft station is opened. But little was added to the depth of the Red Cloud shaft during the week, owing to stoppage to add to the pump columns, but the pump started up again last evening. The new shaft of the South Noonday is down 140 ft, in favorable ground, and a steam engine will shortly be put up to facilitate matters.

#### NEVADA.

**BANNER.**—Nevada Transcript, April 19: Five tons of ore from the 3-ft ledge at the Banner mine, which produced at the surface the marvelously rich specimens a few days ago, has been taken to the Pioneer mill to be worked. It is dark blue in color, being a strong red to the old Banner ore, and is apparently well charged with rich sulphurates. If it pays well a shaft will be put down in that part of the ground immediately. The ledge is also being drifted from the present incline.

**ANOTHER RICH STRIKE.**—Night before last, while a crosscut was being run on the 250 level of the Nevada City mine, a 10-inch ledge of ore that is estimated to be worth \$2,000 a ton was discovered. It runs up a declivity and the shaft has been worked, and up to noon yesterday has been followed a distance of 8 ft and found to maintain its grade.

**BLUE TINT HYDRAULIC MINER.**—The new bedrock tunnel at the Blue Tent mine is now within 350 ft of the first shaft. Mr. Lacy, of the firm of Parke & Lacy, at San Francisco, is here putting in a Barfield drill, which the company has determined to use in order to facilitate the progress of the tunnel. About 100 men, a large number of which are white, find employment in the mine. Five monitors are used for washing, the head of water amounting to 2,600 inches. Supt. Powers says that he hopes to see electric lights introduced in the claim very soon, so that work can be carried on at night the same as by day, as is the case at other large hydraulic mines in the country.

**RICH ROCK.**—There were to be seen yesterday at a business place in town two chunks of ore from a declivity in the district, that would make a Forty-niner smile all over. They showed gold on every side and point, and contained at least \$100 worth of it apiece. That amount was offered for one of them by a shrewd miner, but the owner refused the bid. The formation of the vein matter showed clearly that it was not from a pocket. The holder of the claim is opening it up as rapidly as possible, and within the next few weeks will know just what kind of a strike he has made.

#### PLACER.

**STAIRS.**—Placer Times, April 21: We are informed by good authority that a rich strike has been found in the Golden Bul drift gravel mine over at Lowell Hill. Some very rich gravel has been found while extending the tunnel, which promises a large yield of gold.

**PROSPECTING.**—The Wide West drift gravel mine at Remington Hill is prospecting finely at the present time—in fact a good, rich body of gravel was run into last week, in the main tunnel, and should the find keep up a large amount of gold will be taken out during the next few weeks.

**MICHAEL BLUFF.**—Cor. Placer Herald, April 21: Our little town is full of diggers, quartz sharps, and mining men of all kinds from Virginia City, Salt Lake, San Francisco and other places. Col. Krown is pushing his prospecting tunnel ahead, and seems well satisfied with his prospects. The Rainbow mine is again taking out rich gravel. The old Alabama Bar claim is being fitted up for an active summer's work. It is situated on the South Fork of the Middle Fork of the American river, above Junction Bar. The mine is owned by a San Francisco company, and the work is done under the supervision of Matt Hazlett, who is an old experienced river miner.

**IOWA HILL.**—Cor. Placer Argus, April 23: All the mines are at work, doing their best to utilize the water, knowing that their working days for this season are nearly numbered.

#### PLUMAS.

**OLD STRIPS.**—Greenville Bulletin, April 21: From Supt. Standart, who called on Monday, we learn that work continues without cessation and the mill is running steadily on good rock. It will be but little more than a week before they will also start the Wisconsin mill.

**PLUMAS NATIONAL.**—W. B. Oibert has resigned as superintendent, and is succeeded by Maj. Miles C. Seldio, of San Francisco. The numerous experiments in regard to the process of chlorination, made by Mr. C. H. Aaron, were continued until the entire working was perfectly successful and satisfactory, and there will now be no further interruption. The furnace has a capacity for roasting 3 tons per day, and is under the charge of Mr. Oscar Vogel, who is thoroughly familiar with the business. The west drift is now in about 30 ft, and pay ore is soon expected to be reached. The mill and concentrators are doing excellent work and good results may confidently be soon expected.

#### SAN BERNARDINO.

**ORANGEVIEW DISTRICT.**—Colton Semi-Tropic, April 23: Grapevine district, in which is situated the Waterman mine, is the El Dorado of the hour. The whole section is swarming with prospectors. That the Waterman mine is immensely rich, there can now be no doubt; that other ledges equally rich on the surface have been discovered and located is equally true. Ledges have been located in the neighborhood of the Waterman mine, which promise equivalent wealth with the latter on the surface, and it is reasonable to infer that, on striking, several of them at least will develop a body of ore equal, or nearly equal, in richness to the mine which has already made the Grapevine district famous. Mr. Waterman is now down 80 ft, and the ore continues to increase in richness as he sinks. The shaft is, however, now flooded, and until the water can be pumped out further operations are suspended. The mountain on which the Covington, Horton and Davis ledges are located is some miles from the Waterman camp, but the grade of rock is precisely similar. The Yager and

Meechan ledges are in the immediate neighborhood of the Waterman, and the specimens which they brought in for assay are identical with the surface rock of the Waterman. In short, the indications are good that a great mining section has been discovered. The Grapevine district lies about 95 miles from San Bernardino. The road is good, stations are convenient, and in wood and water easily accessible.

#### SIERRA.

**A FINE PROSPECT.**—Mountain Messenger, April 23: The Bald Mountain Extension Co. got their incline down to bedrock last Tuesday night. A double track has been laid, the cars being hauled up by a windlass, kindly loaned by the Bald Mountain Co. No great amount of water was encountered. When the vicinity of bedrock was reached immense washed quartz boulders were encountered, the largest yet found weighing many tons and requiring some four or five blasts to get rid of it. The bedrock was reached Tuesday morning about 1 o'clock, and from about 4 carloads of gravel \$20 coarse washed gold was obtained. In quality the gold is very fine, assaying about 936 fine. In character and appearance the gold is like that obtained along the ridge for miles above. The company are working 3 shifts of 2 men each, and 6 boys as carmen. (Since receiving the above, a dispatch states that very rich gravel has been struck in this mine.)

**RUBY.**—The Ruby tunnel is in about 1,200 ft and is being rapidly pushed ahead.

**CONSOLIDATED.**—Six men are at work on the Willbourn Con. mine sinking a shaft to bedrock.

**STRIKE.**—The Rainbow quartz ledge is showing better and better as they get ahead. It promises to be a bonanza.

**KEY RICH.**—We are informed that the Busch quartz ledge at Locustville's diggings, is showing a great deal of the very rich rock, and further it is uncovered the richer it gets.

#### TUOLUMNE.

**RICH.**—Tuolumne Independent, April 21: Mr. Haydock, of the Rawhide mine, has struck extremely rich ore north of Jack Arnold's residence. Various rumors are afloat of an exaggerated character—that is not uncommon among many here, on any proposition. We saw a number of very large pieces that would go from \$10,000 to \$20,000 per ton.

**OLSEN.**—The management of the Olsen mine seem to be determined to work it for all it is worth, and show sound policy in employing those settlers with families living around the place whose interests are identified with that of the mine instead of employing strangers. In sinking the mine, we understand that the vein of black sulphur ore is widening rapidly; but little is said about it, however, on the outside. This ore assays \$60 per ton. The Olsen Extension, owned by the Olsen family, is to be reopened. The Peck, Johnson and Fayland claims, on the extension of the same vein as the Olsen, have all of them good prospects—the Johnson claim having streaks of ore which will pan out from \$1 to \$3 to the pan.

#### NEVADA.

##### WASHOE DISTRICT.

**CON. VIRGINIA.**—Enterprise, April 24: During the past week 45 1/2 tons of ore, assaying \$20.95 per ton, have been extracted and sent to the mill; the Joint Best & Belcher upraise has been extended 15 ft. On the 2500 level the joint California, and the C. & C. shaft has been extended 27 ft, and the joint California east drift from the C. & C. shaft has been timbered up and extended 15 ft.

**CALIFORNIA.**—During the past week 504 tons of ore, assaying \$22.75, have been extracted and sent to the mill. On the 2500 level have completed a chamber for the joint Ophir east winze and sunk and timbered the winze 5 ft. On the 2500 level the north lateral drift has been advanced 40 ft; total, 900 ft. The joint Union Con. east winze has been sunk and timbered 17 ft; total depth, 73 ft. Ore raised during the week, 271,160-000 tons.

**UNION SHAFT.**—The shaft has been sunk and timbered 8 ft. Are upraising at the 1600 and 2500 stations. C. & C. SHAFT.—Nothing except preparatory work can be done in the shaft until after the air connection on the 2500 level is made.

**HALE & MORSEKOS.**—Have started a crosscut west on the 1400 level at a point 120 ft south of the Savage Incline. During the past week have sunk and timbered the shaft 27 ft; total depth, 1,939 ft.

**UNION CON.**—On the 2500 level are cutting out a chamber for a winze joint with the Mexican in the east crosscut.

**MEXICAN.**—On the 2500 level are cutting out a chamber for winze in joint Union Con. east crosscut.

**ORNER.**—On the 2500 level have completed the chamber for a winze in the joint California east crosscut and have sunk and timbered the winze 5 ft.

**SIERRA NEVADA.**—On the 2400 level east winze No. 2 has been sunk and timbered 26 ft; total depth, 33 ft.

#### ESMERALDA DISTRICT.

**ORINDINO AWAY.**—Esmeralda Herald, April 23: The little mill is still grinding away on that 12 tons of ore from the No. 2 Esmeralda mine, and it is said it will take until about Monday night to finish the lot—8 days to grind 12 tons. The sound of the little stamps and toot of the toy-whistle is better than no music at all.

**WHAT IS GOING ON.**—The Del Monte Co. are considering the feasibility of running a drain tunnel to tap the mine at the depth of about 10,000 ft, thus not only enabling that company to prospect their property thoroughly without being bothered with water, but also draining the whole district. The New Esmeralda Con. is having 12 tons of ore crushed, and if it is demonstrated by actual working process that the thousands of tons of the same kind of ore now in sight will pay to mill, that necessary article will be created. New York parties have incorporated the McIntosh & Barnes, and are talking strongly of a mill. The probability is that the Cook Bros. will accept the prospect on the last next month, which will mean business on a large scale. Supt. W. H. Buckley is handling the Cortez and the company owning the property propose to erect a mill. A rich company will probably take hold of the famous Centennial and pull out the pure stuff this summer, and many other kites of smaller dimensions are flying about the old war-horse camp of Aurora. That our prospects are far brighter in a mining point of view than for the past 15 years there is no room for doubt.

**NEW ESMERALDA.**—A drift is being run from the main tunnel south, and is now in 10 ft, the face showing the same character of rich ore as found on the Hancock.

**CORTAZ.**—Ore from the mine is steadily accumulating on the dump.

**THE PROSPECTORS.**—The regular complement of men is still employed.

**HUNTER WEST.**—The 65-ft contract is rapidly nearing completion.

#### EUREKA DISTRICT.

**TUNNEL.**—Sentinel, April 23, During the past day or two there has been encountered in the Eureka tunnel, and there are now some 3 inches at the face of the tunnel. The striking of water is looked upon as favorable for a change of formation.

#### GRANTSVILLE DISTRICT.

**THE ALEXANDER.**—Bonanza, April 23: In the Alexander work progresses rapidly. At the bottom of the incline the station and camp, preparatory to running level No. 7, are nearly done. Every indication shows that No. 7 will have the same body of ore as was found in No. 6, but of higher grade. The mine is now furnishing an abundant supply of water for the mill, without having to call upon other resources. The mill is running in splendid style, with no stoppages and excellent results. The bullion produced averages nearly 900 fine.

**THE HOMESTEAD.**—Work goes on in the Homestead, both in tunnel and shaft. Some very fine chloride ore has been discovered.

**THE HORTON.**—The shaft has attained a depth of over 100 ft, the bottom in nice looking ore.

**THE VESTA.**—It is understood that very shortly a

wealthy company will take hold of and work it vigorously.

**THE BROOKLYN.**—In the Brooklyn an upraise from the crosscut on No. 2 is in a large body of fine grade ore.

#### OSCEOLA DISTRICT.

**DITCH.**—Ward Refex, April 16: Work on the water ditch that is to bring water to the placers of Osceola, it is reported, will be commenced on or about the 10th of May next. It may be so, "but you can't always sometimes most generally toll."

#### PIOCHE DISTRICT.

**ORE.**—Ward Refex, April 23: There has been a large quantity of chlorides ore hoisted out of the Meadow Valley mine the past week. The greater portion of this ore is rich chloride, and the owners expect to make a small little sum from the same. There were two train loads of ore brought to the Dry Valley mill the early part of the week, but owing to repairing the track no more could be shipped. The ore chutes and platform at No. 3 works are all fixed and covered with ore awaiting shipment, and considerable yet in the mine to hoist. No hoisting has been done for the past 3 days, owing to there being no room on top for any more ore until another shipment is made.

#### TAYLOR DISTRICT.

**STRIKE.**—Ward Refex, April 16: Another strike was made in the district a few days ago while grading for a road, an assay from which went \$135 to the ton. Mr. Ople says Taylor is the biggest prospect he has seen in many years. All who have visited Taylor lately join him in that opinion.

#### WHITE PINE DISTRICT.

**CONNECTION.**—Ward Refex, April 16: Connection has been made between the incline and Eberhardt tunnel, and the latest advice is to the effect that four crosscuts will be started immediately, to prospect ground on both sides of the tunnel.

#### ARIZONA.

**STRIKE.**—Cor. Arizona Journal, April 23: Since my last letter there has been a big strike in the Empire mine. They have been trying to keep the matter quiet until they knew just what it amounted to, but like all good news it leaked out and has created quite a stir in mining circles. This continues the East bonanza 1500 ft further northward, and almost assures ore in the Mesa mines. This line of bonanzas commences on the south with Grand Central, comes north into Contention, Head Center and Empire, making all told, about 6,000 feet of ore ground, mostly very rich. The main strike is similar to the rich chloride and horn silver gold ore in Head Center.

**THE MESA CON.** has incorporated and will proceed to develop their property immediately. This consists of 15 locations in a solid block, being 3 in width by 5 in length, directly in line of the heart of the ore belt as now developed.

**A HEAVY SUIT.**—Richard Gird, late Supt. of the Tombstone M. & M. Co., has brought suit against the company for the sum of \$30,000, alleging as a cause of action, that last October he loaned the company \$40,000, and that the company has withheld dividends on its stock to the amount of \$40,000 more. It looks now as though there might be a good-sized washing of dirty linen. It is a query what a dividend-paying company could go to with a loan from their superintendent of so large a sum as \$40,000. Could they have borrowed money with which to pay dividends? If not, what for? The public will not have long to wait to know, if the suit isn't settled without appeal to the courts.

#### COLORADO.

**CHALK CREEK.**—Cheffee Times, April 23: The Collum Kill lode is the new strike on Sugar Loaf mountain, near the Iron City smelter, lately made by Geo. L. Wright, Esq., the manager. There has been a drift of 15 ft on the vein, which discloses a pay streak of only 2 inches of remarkable value. It assays 90 ounces in silver, 14 ounces in gold and over 60% lead to the ton. The Hamlet lode will stop work for the present. It is probably rumored that a body of 700-ounces ore has been encountered in the second level of the Hortense.

**TROUT CREEK.**—We have been shown 3 assays, which gave 36, 40 and 82 ounces in silver to the ton. The lode is located on Iron Chest hill, about 1,500 ft southeast of the Iron Chest mine. Another strike made on Walker's hill, about 2 miles northwest, of sand carbonates is also causing considerable interest, though we have not been able to learn the particulars. We understand that a fire in the Forest City has been sold for \$2,500, and a interest in a group on Walker's hill for \$1,000, by Berry & Massie.

**COTTONWOOD DISTRICT.**—The Stars and Stripes is a new location in South Cottonwood which assays 27 ounces silver to the ton on the surface and shows a 2-ft vein. The snow is going off rapidly, and soon the hills will resound with the music of the blast and the season will be fairly opened.

**MONARCH DISTRICT.**—Henry Altman, who is now in New York, has formed a company with a capital stock of \$500,000 for the purpose of working 3 tunnels in the North Park basin. A working capital of \$25,000 has been secured. V. B. Purdum has returned from the East, where he organized the Continental M. Co., with a stock of \$175,000, at \$20 a share. The mines owned by this company are the Red Lion, Brigham Young, Lady Lurly, Cabin Boy, Jennie C. and Silver Wave, all of which promise to turn out bonanzas. The Sleeping Pet, owned by Messrs. Cramp, Eastman & Withington, is located on the Tomichi and is one of the best mines in Colorado. The owners will put in a pump and hoisting machine as soon as possible and work the mine to its full capacity. Ore from this mine assays from \$200 to \$250,000 per ton.

#### IDAHO.

**WOON RIVER.**—Cor. Salt Lake Tribune, April 24: The roads into the place are more of a matter of interest to your readers who contemplate coming here than anything else. The Kelton road is now very good up to a point 13 miles south of this town, and loaded teams can get in that far with perfect ease, with good feed for teams all the way. Then for eight miles north the road is as soft as possible, but after getting into the Wood River valley proper, the road—10 miles to Bellevue—is good. The Blackfoot coach is coming through and freight teams are beginning to come in lively. This town is full of men, principally from Nevada, and a large number has gone on to the camps up the river, and still the boys continue to arrive at the rate of about 100 per day. The hotels are full, provisions are scarce, and prices high. Bellevue is rapidly growing, new cabins going up everywhere. Town lots on Main street command prices as high as \$100, and \$500, according to location. Prospecting in the neighboring hills is lively, and some nice looking ore is being brought in. On the whole, Wood River is just entering upon an immense boom, unparalleled by anything except that of Leadville.

**SHAW'S MOUNTAIN.**—Cor. Idaho World, April 16: Our camp has begun to loom up once more. A great moon is at work in the Rising sun, extracting ore from the mine will soon be put through Plowman's mill. Mr. Thurman is driving two tunnels on the ledge, and he expects to keep the mill running all this summer. He pays \$2.50 per day, the miners working themselves. An expert miner will now and then work for these small wages, but only long enough to get a stake to go to some other camp. Joe. Robert is driving the Paymaster tunnel, and is now driving the Plowman's mill, crushing 37 tons of North Star ore, which will go \$20 to \$25 per ton. Mr. Thurman has a small force of men at work on the new furnace at the mill. He intends to roast the Rising Sun ore. The Paymaster rock that Bayhouse put through the mill was roasted on a log heap and then thrown into concentrated live water while it was hot, so it soaked up a great deal of live steam and the plates in better order, and the result was \$55 per ton. The same class of ore was put through last summer and gave only \$35 per ton; so you see all this rock needs roasting.

#### MONTANA.

**ALICE.**—Butte Miner, April 19: The strike of rich ore at a depth of 700 ft in the Alice mine, was a discovery of great importance to the stockholders of the company, as well as to the general mining industry of this district, for it established, beyond a doubt, the existence of rich ore at a great depth, and further, that instead of the value of this section showing indications of barrenness as they are next, it may be so, "but you can't always sometimes more compact in their formation. This late development in the Alice demonstrates this fact and puts the question at rest. The ore is running higher at both of the mills and the assays from the battery samples show an increased value of \$10 per ton. Yesterday the bullion shipments of the Alice company was valued at \$7,000.

**GOLDEN RULE.**—The strike of rich ore in the main shaft of the Golden Rule mine has induced the owners, Messrs. Tom Weller & Co., to put steam hoisting works on the mine. For the past two weeks the Co. has been engaged in erecting works, which are nearly completed and ready for hoisting operations.

**MOUTON.**—Last night the three-compartment main shaft of the Mouton mine had reached a depth of 283 ft, in excellent condition. In the last few ft a decided change for the better in the ore was noted. The bottom of the shaft has been noticed, and it is now much safer than heretofore, which will facilitate the dropping of the shaft with greater dispatch.

**MAGNA CHARTA.**—In the different workings of the Magna Charta mine the looking well. The bonanza streak of ore lately noticed are all holding their own, and are showing uniformly in thickness and the assay value of the ore daily extracted from the mine.

**BELL.**—The ore out pit of the mine is about 30 tons per diem. This ore is piled upon the dump, supposedly to await the erection of smelting works by the Bell Co.

#### NEW MEXICO.

**COLFAX COUNTY PLACERS.**—News and Press, April 14: With the going of winter and the coming of summer, and the abundance of water, placer mining has again been inaugurated in the old camps of Ute and Willow Creeks adjacent to Elizabethtown. The Centon, whose claim is in the Moreno, have been drifting all winter and the labor has been rewarded by the uncovering of a fine streak of rich gravel which they are now washing. Last week a run of five days was followed by a clean up which netted the boys about 25 ounces. On the 4th Mr. Lynch, with quite a force of men begun cleaning out the lower Moreno ditch, and on Monday last commenced washing on Michigan. He is also doing fine gulches and getting everything in order to hydraulic in the big cut on the Flat, as soon as the water comes through the big ditch.

**TAOS NOTES.**—Mining excitement still continues; lots of Colorado prospectors are coming in. Several very good carbonate lodes have been discovered between the Arroyo Hondo and Red river, which prospect well. Many of the mine owners on the Arroyo Hondo have commenced work in earnest and almost all of them are sanguine of success. Frazier & Co. have struck it big in their tunnel, free gold ore in a long vein that runs away up into the thousands. On the Arroyo Hondo some wonderful developments have been made. McGraw & Sam have struck in their tunnel a four ft vein of galena that is almost pure silver—60 to 75%. Some assays of Mr. Stertz from the Picuris run up to 50 and 100 ounces in silver and some gold. The Picuris mines no doubt are very rich.

#### OREGON.

**FOOT'S CREEK.**—Oregon Sentinel, April 23: We found a number of the miners still working away on their claims, though with a diminished head of water; others were engaged in cleaning up. Judging from the amount of ground worked over on this fork of Foot's creek a profitable yield of gold will result. The mines on the right bank fork of Foot's creek are scarcely opened yet. The mining claims of Messrs. Duffield, Lance & Hosmer we consider among the best in the State. All ground worked so far has prospected uniformly at 25 cents to the cubic ft. What this claim needs to make it the best in the country is a greater volume of water. Since this mine has been opened only about a quarter of an acre of ground has been worked over, with the bedrock ranging from 15 to 20 ft below the surface.

**ROCK POINT.**—Mr. Jamison, of Rock Point, tells us that Byrd and Fisher's big ditch out of Rock river to water Big Ber is under way, about one half mile being finished. The ditch will carry about 2,000 inches of water. The claim of Duffield, Lance and Hosmer, on Foot's creek is one of the best in the country. It will average about 20 ft in depth, prospecting uniformly 25 cents to the cubic ft, while the bed rock is very rich. These gentlemen have only washed off about a quarter of an acre, and have yielded over \$10,000 worth of gold in several years. Two giants are still in operation at Sterling, and nearly twice the amount of dirt washed last season has already gone through the flume. The Holman ledge is still being prospected by Richard Cook, who, it is said, has struck some small veins of very rich silver ore.

**NUOGETS.**—Democratic News, April 22: D. M. Marden, of Willow Springs, who is now cleaning up, has picked up several pieces of gold of late, some weighing as high as \$15. Enoch Roten, of Willow Springs, picked up a piece of quartz in his diggings the other day, from which he realized two ounces of gold. We learn that the company which has the Applegate Oravel Co.'s diggings leased intended suspending operations, finding recent clean ups unprofitable. Two nuggets were last week found in Yauces, Salmarsch & Co.'s claim at Sterling, weighing 830 and 812 respectively. Bybee & Fisher's ditch to the big fork of Rogue river will be done in less than two months. J. T. Layton, of Farris gulch, is about putting in a Giant with a six-inch nozzle, and enlarging the size of his flume. Green Bros., of Oallie creek, have suspended crushing quartz and are now engaged in running a tunnel to tap their ledge lower down.

#### UTAH.

**PARK CITY.**—Cor. Salt Lake Tribune, April 23: There is no disputing the fact that the present season will witness a boom in Park City, such as Wood River might do well to baffle for. We do not expect or want to see men coming in at the rate of 100 a day, unless they come to stay. Those who come will be valuable accessions to our camp, and will aid in opening up the rich fissure veins, which, it is true, require the expenditure of more time and more capital than the majority of the veins in the country. Slowly they have developed their claims one by one, often gladly selling at a trifling price good prospects, that they might have means to work others, and gradually the true value of many of these prospects are becoming known. Of all the properties that have been well opened, and upon which as much as \$5,000 and over has been expended, there is but one that has in any real sense failed. Nothing is more certain than a rich return for money judiciously invested here. The district embraces a large scope of country, much of which has not yet been prospected. The mineral belt is strong and wide, with plenty of room for scores of good mines, so no one need fear that the field is all occupied.

**THE CROSSCUT IN ORO** struck the front ledge on Thursday, and the stock quickly felt the improvement. The strike is of great importance to Bodie district.

**THE GENERAL CUSTER** mine, of Bonanza City, Idaho, produced 50 bars of bullion between February 11th and March 22d, valued at \$103,600.

## Meeting of the Railroad Commission.

There was a meeting of the Railroad Commission in this city recently. During the session there was present representatives of the leading railway companies, and a general discussion of the reduction of fares and freights was had. It seems from the reports in the daily papers that there was a direct issue between the members of the commission as to fixing upon a schedule of rates, and the result was that the matter was postponed until the meeting of May 11, 1881.

At the Saturday afternoon session of the Board reporters were strictly excluded, the watchful halliff seating himself near the door to see that the secrecy of the executive meeting privacy was not invaded. The following resolution was introduced by Commissioner Beerstecher:

*Resolved*, By the Board of Railroad Commissioners, that the following schedule of freight rates go into force and effect on the 1st day of June, 1881, on the several railroads within the State, upon whose lines the places named in the schedule are situated, and that such rates take the place of the rates now in force on said roads for the transportation of the articles named in the schedule, and between the points named, and that on and after the 1st day of June, 1881, it be unlawful to demand or receive rates in excess of the rates so fixed and established in this schedule, and, if through any error in the schedule hereto, or rate for carriage of freight appears in excess of the present rates, then the present rates shall prevail until corrected by this Board.

That the rates for carriage of freight on the Central Pacific, its branches and leased lines within this State, the Southern Pacific, California Pacific, and Northern, Stockton and Copperopolis, San Pablo and Tulare railroads, as the same are now in force and effect and on file in the office of this Board, are adopted, fixed and established as the freight rates of this Board, subject to the changes aforesaid as appearing in the schedule hereto, and subject further to all just and reasonable changes and alterations hereafter as such changes and alterations may appear desirable, just and equitable, after due notice and hearing of parties interested.

*Resolved*, That these resolutions be printed and served on the several railroad companies affected, by the halliff of this Board.

## General Stoneman Protests.

The first paragraph of the resolutions, which referred to the adoption of the schedule of rates offered by Mr. Towne at the morning session, was accepted by Commissioner Stoneman. The schedule makes a reduction on the transportation of grain of all kinds, alfalfa, cattle, and what may be generally called staple articles. The reduction has been variously estimated, but Commissioner Stoneman states that it is probably about 10%. Commissioner Stoneman, however, objected to the second paragraph of the resolution, which adopts the schedule of freights now in force for all articles except staple ones, such as grain, etc. The effect of the resolution, if adopted altogether, would therefore be to secure a reduction of about 10% on freights for grain and cattle and leave the present rates for merchandise, etc., intact. Commissioner Stoneman warmly opposed the adoption of the latter part of the resolution, and for two hours the Board was widely divided in its views, and stubbornly determined to remain so.

General Stoneman offered the following:

The act to organize and define the powers of the Board of Railroad Commissioners contemplated that the opinions of the Board shall be given in writing, and as a member of the Board I ask that the consideration of the resolution adopting the schedule fixed by the railroad mentioned in the resolution be laid over until the next session, in order that I may have an opportunity to state my reasons in writing for my vote and any action I may think proper to take in the matter.

So ordered by the Board.

It was ordered by the Board that the appearance of the several railroad companies heretofore served by the halliff of the Board under the order of this Board with printed resolutions and schedule of tariff rates for transportation of passengers, and printed summons to appear and answer within 15 days after service, and show cause why such rates should not be established and go into force and effect, be entered, and that the hearing upon the several summons be adjourned to the 11th day of May, 1881, at 10 o'clock A. M.

**SALMON RIVER MINES.**—A correspondent writes from Salmon river that the mines in that region are opening out beyond all expectation, and that the various camps along that stream will have a veritable boom this spring—not a second-class or ephemeral spurt, but a substantial upheaval, the mines being very rich and the business prospects of the most encouraging kind. The work during the winter has been extensive, and a number of very rich strikes have been made, which show that the region is not half prospected. A large quantity of first-class ore, averaging about \$300 per ton, has been taken out of the various mines, and will be shipped to the furnaces as soon as the snow is off the ground. The furnaces are preparing to start up, and will have a good summer's run, and it is quite likely that several new ones will be constructed. Challis is building up, and promises to be quite a large town, and will, no doubt, become the county seat of Custer county. The latest and biggest strike made recently was in the Faithful Boy, on Poverty Flat, where an extensive body of 800-ounce ore was found. A smelter is also to be erected on Squaw creek, where a great deal of ore awaits reduction. From these showings the Salmon river country bids fair to divide the honors with Wood river the ensuing season.

The *Free Lance* says: James Phillips died in Grass Valley Sunday. When he came to this coast some three years ago he had with him what is known as a "divining rod," or "hoodoo," an electric instrument by which it is thought gold may be found, but we believe it proved a failure.

## North Columbia.

North Columbia, or Columbia Hill as it is more commonly called, is located about seven miles in a northeasterly direction from North San Juan. The place contains a population of about 250 souls. There are several foot-hill ranches located around the suburbs of the village, but the place is dependent upon hydraulic mining. The mining interests are almost wholly in the possession of the Eureka Lake M. Co. of which R. McMurray, Esq., is superintendent. His company is operating three sets of claims which furnish steady employment to about 40 men, and indirectly, at cleaning-up times, to several more. Mr. A. S. Bigelow has a general supervision of the company's operations there with a foreman in charge of each mine. William Huff has charge of the Farrell; Chas. Gallagher of the Laird; and Martio Phelan of the Consolidated, these being the names by which the claims are respectively designated. The mines yield a rich harvest of the precious metals to the company, and the tract of rich auriferous, ancient river channel owned by it, is very large. Only a small portion of the top portion has been washed away as yet, and the richness of the bottom of the channel can only be conjectured. The company are about testing the matter to ascertain to a certainty. A shaft was recently sunk 132 ft, when bedrock was reached, which was found to be the rim of the channel. From the bottom of this shaft a tunnel was extended across the channel a distance of 780 ft, to the rim on the other side. The gravel is rich for hydraulic purposes as far as prospected. The machinery used in sinking this first shaft has been moved about 400 ft, to a point supposed to be over the center of the channel, and a new perpendicular shaft is to be sunk, to try and reach bedrock in the middle of the channel. The object is to ascertain how rich it may be, and whether it can be profitably worked by the drifting process. The present outlets do not afford an opportunity to work the mines only in part, merely to wash off the surface. To get an outlet for all the vast body of rich gravel which will remain after the surface has been washed away, will require a long tunnel from either the middle or south Yuba, and in either case the expense of running would be very great, so that with the present agitation on the debris question the company will be rather timid about undertaking so expensive an enterprise. Should the gravel be found sufficiently rich to justify working by the drifting process, it will furnish employment to many more laborers. The point where the shaft is being sunk is nearly directly underneath where the old town was located.—*San Juan Times*.

## Suggestions to Eastern Capitalists.

Eastern capitalists in search of fortunes in Arizona have occasionally failed to find them and have discovered rocks instead, upon which they have wrecked themselves, simply because they did not pay proper attention to well-known business principles. They have in several instances sent parties to our Territory to represent their interests, who, while they may have been good business men in the ordinary acceptance of the term, knew nothing whatever about mining or mines.

The old saying, that a saffaring man will bankrupt himself on a farm, applies with equal force in any other walks of life. A printer would cut a bad figure probably as a wholesale grocer, and a grocer would not make his fortune as a shoemaker. To send a person to a country to examine mines, and invest in them, who knows nothing about them is equivalent to throwing money away. Nothing in the world requires more thorough and practical knowledge for successful working than mines of gold and silver. It is a knowledge, too, which must be acquired by experience, and a very bitter experience, as a general rule.

It is for this reason that some of the best mining properties in Arizona are to-day under a cloud. Had one-third of the money thrown away in blundering efforts to develop them been judiciously expended they would be now among the most productive properties in the Territory.

Sending incompetent men to examine mining properties is a two-edged sword. It cuts both ways. It disgusts those who are so inconsiderate as to depend on these men, and it gives a bad name to the district where they have invested. Thoroughly trained and competent mining men can always be secured, whose judgment is seldom at fault, and who are not likely to throw away large sums of money foolishly. They have learned their business by serving a long and sometimes eventful apprenticeship, and it would be the part of wisdom for Eastern capitalists to employ these, both to examine and work their properties.—*Arizona Journal*.

**ALASKA MINES.**—The new mining district is all covered with snow, which is from six to ten ft. deep. Two tons of ore were blasted out on the Pilz lode, which will be forwarded to San Francisco for reduction. Some claims have been jumped in the new mines, and serious trouble is expected. There are 200 miners at Harrisburg awaiting the disappearance of the snow.

The Copper Queen mine, Arizona, has been sold for \$1,250,000, to a New York company. This is a copper mine and its product has netted eight cents a pound profit. It produces over 300,000 lbs. of copper a month.

## The Taos Mountains, New Mexico.

A correspondent of the *News and Press* says: That the Taos mountains are as rich in mineral as any in New Mexico, is beyond the question of a doubt. On the east side for years they have been noted for mineral, and until lately nothing has been done on the west side to develop its mineral.

A few go-ahead prospectors came in here last summer, many of them with but little means, as prospectors generally are, yet see the results. Good mineral, both in placer and lodes, has been discovered on all the six or seven little streams which flow into Taos valley. There is only one exception, the Rio Puelho, the center one, and no doubt the richest of any, but the Indians owning (or occupying, I had better say) a small scope of country at its entrance to the valley, will not allow any prospecting to be done on the stream.

In my opinion that objection will not last long, for it is well known that there is lots of good mineral on that creek, and how could it be otherwise when it is surrounded by mineral. Some placer mines have been discovered and located on the Rio Chiquito, by prospectors from Leadville in the last few days, and they think the creek will pay very well. The lode discovered on the head of the same creek runs away up into the hundreds, so I am informed by those who have seen the assay report. The Taos creek placer mines have been bonded for \$10,000, and parties are making preparations to work them on an extensive scale. Litz & Son have also bonDED their claim for a large amount, so I am reliably informed. I have seen some very flattering reports from the Picuris mines, as also from the Arroyo Honda.

Several parties are making arrangements to ship ore to Denver, and from the assays received, there is no doubt but that it will pay well. Developments of rich mineral are of almost daily occurrence here, and it is nothing, in my opinion, to what it will be in a short time. We are going to have a perfect stampede to this camp shortly. In my next I will give you some figures from assays of the different camps in this district.

The Kanchos of Taos is improving rapidly; it looks as though it would be the coming town in this valley and would be a good place for a smelter, as there is plenty of good ore in the immediate vicinity and good coaking coal to smelt with. A few good mechanics would do well here, a blacksmith and some carpenters.

## The Mohave Mines.

All the information which reaches us from these mines is of the most encouraging character. A new mill is being put up there. With this mill available we may count on bullion returns from the Mohave mines from this time forward. The mines extend for nine miles in one direction, and good prospects have been had along the entire ledge or series of ledges. Some of the ore is remarkably rich. Gold predominates, although it is believed that as depth is attained silver will become the chief metal. While a great portion of the ore is of a milling quality, there are strata that will require smelting. These mines are all, or nearly all, owned by Los Angeles people, whose capital and enterprise have developed them. They are located in a beautiful and picturesque locality, and have the great advantages of wood and water in abundance in their immediate vicinity.

There is a great mass of ore out on the dumps, so that when the mill is started it will have a supply to keep it going indefinitely. These mines have now been so thoroughly prospected, and the character of the ore has been so positively determined, that no reasonable doubt can be entertained either of their great value or permanency. The coming summer will witness great activity in their working, and a very large number of people will find employment in them. Indeed we may safely look for a very important camp or mining town to spring up there, and quite an extensive trade will then arise between our city and the Mohave district.

We see that the papers of San Bernardino are urging their Supervisors to improve the road across the mountains by way of the Cajon pass to these mines. They say that if this be not done, the Mohave miners will make connection between this city and their camp by way of a station near Ravenna, on the Southern Pacific railroad. We are told that there is little or no difficulty in reaching that station. It might be well for our merchants to look into this matter. If Mohave camp is to become, as it is believed it will, an important mining center, its trade is worth making some exertion to secure.—*Los Angeles Express*.

**NEW LAUNCH.**—At a recent meeting of the Polytechnic Club of the American Institute, the president, Mr. T. D. Stetson, gave some details of a very small steam launch just completed by the Herreshoff Manufacturing Co., of Bristol, R. I., for P. Lorillard, of New York, having a complete condensing compound engine, weighing only 175 lbs., rated as 8-horse power, and running with steam at 150 lbs. pressure from a Herreshoff coil boiler, with a grate 22 inches diameter. The cylinders are 2½ and 4 inches in diameter. Running without resistance this complex engine has made as high 1,150 revolutions per minute. The launch for which the engine was built is 30 ft. long and 5 ft. wide, with a planking entirely of mahogany and a lining of pine laid diagonally, fastened with brass screws. Weight of boat and machinery, 1,800 lbs. Her guarantee speed is nine miles.

## The Pacific Business College.

Readers have doubtless often noticed the handsome engraving of the Pacific Business College, which appears from time to time in our advertising columns, and would like to know more about the institution thus placed prominently before them. The Pacific Business College was the first established commercial school on this coast. Through its intrinsic merits it has gained a reputation for thoroughness and system second to no institution of the kind on the continent; and as a consequence, it enjoys a patronage not only from all parts of this coast, but from adjacent territories, Mexico and South America. The college is endorsed by the prominent business men of the country, by the leading journals, and by eminent educators generally. The proprietors—Professors W. E. Chamberlain, Jr., and T. A. Robinson—are so well and favorably known in educational circles throughout the coast, as being eminently fitted for these responsible positions they occupy, that they require no commendation from us. These gentlemen are ably supported in their work by a full corps of teachers thoroughly qualified for their respective duties.

The college is located at 320 Post street, opposite Union square, and occupies the entire upper story of the Red Men's building. The site is one of the most desirable in San Francisco, as it commands a splendid view of the city and its environs, and is convenient to this leading thoroughfare, while sufficiently removed from their bustle and excitement. Union square is one of the most attractive and picturesque breathing spots in the city.

## Courses of Study.

These have been specially prepared to meet the requirements of business life; and no person of ordinary ability and application can complete a course of instruction in the Pacific Business College without becoming well qualified for the practical duties to which the studies pursued refer. The courses of study, and methods of imparting instruction are thorough and practical, and fully up with the demands of the age. The system pursued is peculiar to this college, and is well calculated to accomplish the desired results.

The commercial course is thorough and comprehensive. A system of actual business is employed, combining theory and practice in the most perfect manner, and is at once so simple and natural that it needs only an examination of its merits to convince the most skeptical of its superiority over all other systems. Book-keeping by both double and single entry as applied to all kinds of business, penmanship, commercial calculations, business correspondence, business forms, wholesale and retail merchandising, commission and forwarding, etc., etc. Commercial law, political economy, business ethics and other subjects of interest receive that attention which their importance demands. The student buys, sells, ships, consigns, discounts, insures, draws checks, notes and drafts, etc., and goes through the entire routine of actual business. There is in active operation a banking house, with checks, drafts, notes, bills of exchange, certificates of deposit, etc., fully illustrating the banking business. Students receive while attending this school the same practice in conducting business affairs that they would in a bona fide bank, office or counting house.

The telegraphic course is unsurpassed, and includes everything requisite to make students proficient operators.

The academic course is designed to give regular and systematic training in ordinary English and advanced mathematical branches, and to prepare those who need elementary education to enter upon the commercial course with a better foundation, and with more certainty of success. It furnishes thorough instruction in spelling, reading, arithmetic, penmanship, English grammar, letter writing, rhetoric, etc., also in algebra, geometry, mensuration, surveying, navigation, etc., including the differential and integral calculus. Students can make arrangements for studying the modern languages or other special branches; and they have the privilege of combining the studies of the different courses on very reasonable terms.

## Individual Instruction.

In the business course the class system is entirely discarded. Students receive such individual instruction in the several departments as enables them to pursue their studies as rapidly as their ability will admit. No student, therefore, is kept back in his course by those of less ability and application. On the contrary, he is always advanced as rapidly as is compatible with thoroughness. Ladies are admitted into all the departments of the college, and have in every respect the same advantages as the other sex. The tendency of the age is to remove all obstacles that have hitherto prevented women from competing with men in the different professions and industries. One of these disabilities is found in the fact that girls have not been properly educated for the practical duties of life.

These are some of the leading points of this institution. There is much other information of importance which can be gained from the publications of the college, which can be had by addressing the proprietors at 320 Post street, San Francisco.

The Merrifield mine, Nevada county, is having its stamps increased from 20 to 40.

## THE ENGINEER.

## The Future of American Railroads.

An English journal speaks as follows of the future of railroads in the United States: There are two powerful influences at work which certainly seem to show that American railroads have entered upon a new era in their history. Immigration into the United States is now taking place upon such an extensive scale that the Republic is being occupied and developed with a rapidity which would have been pronounced impossible and fabulous 20 or 30 years since. With the help of emigration from Europe and with the natural excess of births over deaths, it does not appear too much to assume that the population of the Great Republic, which now stands at about 50,000,000, will be carried, by 1890, to 62,000,000. In other words, we may estimate the average growth of the population of the United States during the next ten years at 1,200,000 per annum. It is almost difficult to over-calculate the effects which the efforts of 12,000,000 new inhabitants will exert upon the United States between 1880 and 1890. Villages will become towns, towns will expand into capitals, and wildernesses will be made populous. We must bear in mind that during the next decade there will be not only a growth of human power in the United States, but that there will be a development of steam power as well. The effect of all this will be marvelous.

Another circumstance which is exerting just now a very great influence upon American commerce and American railroads is the decline in the value of money to a more reasonable level. American have not been slow to profit from the cheapness of money in Europe; it may be said, indeed, that they have assisted to produce that cheapness. Ten years since the United States Treasury had considerable difficulty in floating 5% bonds of the Republic; but now, in consequence of the growth of American wealth and credit, and the remarkably low rates current for capital on this side of the Atlantic, the American Government can raise all the funds of which it may stand in need at 3½% to 4% per annum. The best of the American State Governments are also beginning to howl at 4½% per annum, or 5% per annum, and 5% per annum is becoming an outside rate in connection with new bonds issued by American railroad companies. The effect of all this upon the work of American railroad construction and upon American enterprise generally, must necessarily be very great and very encouraging.

## Impromptu Ingenuity.

Ready tact and ingenuity is sometimes of more value, especially in an emergency, than mere mechanical skill. As an instance to point the following may be cited:

Some years ago, a Spanish steamer, while crossing the Bay of Biscay in a severe storm, gave such indications, by an unusual noise at the stern, that there was something wrong with the screw propeller or its shaft outside of the ship—that is, the open space between the stern and rudder posts where the screw revolves. There was no dry dock in any of the ports on the coast where the ship could go to be examined; and on arrival at Vigo it appeared as if there was no alternative but to remove the cargo from the stern, and by placing it forward thus lift the screw propeller and shaft to the surface of the water. The alternative, simple as it was, meant a serious delay and great expense.

Before commencing to remove the cargo, another consultation was held. It was then decided to put the stern of the ship over a bed of light colored sand; and as the water was very clear, there might be a possibility of ascertaining the extent or cause of the mishap. For two days after the vessel was so placed, the wind caused a ripple on the water, which effectually prevented anything being seen. It was then suggested by some one on board to try the use of oil on the surface of the water round the stern of the ship. The effect was most satisfactory. The water was hecalmed as if by magic, and it was then seen that the wedge or key which keeps the propeller in its place on the shaft had come partly out, and thus left the screw loose on the shaft, which caused the noise. By continuing the use of oil for a few hours the wedge was ultimately driven into its place and secured. Many days of detention, and the use of costly appliances and labor were thus saved.

A HOME COMPLIMENT.—The recent appointment of N. W. Spaulding, of Oakland, as U. S. Assistant Treasurer, vice Wm. Sherman, will give general satisfaction to the people of California. Few of our citizens are more widely known and respected. When he took an active interest in the politics of Oakland he was repeatedly elected Mayor, and was a vigilant and conscientious official. As a member of the Council, his name will always be associated with some of the most important local measures. He was the father of the present complete system of Oakland's street improvements, and by its adoption, that city has saved millions of dollars. In any capacity in which he has ever served he has won the admiration and esteem of those who knew him best, and thousands will be glad to learn that he has now received one of the most prominent Federal appointments on the Pacific coast.—*Alameda Encinal.*

## USEFUL INFORMATION.

## A New Substitute for Rubber.

In this early future india rubber ought not to be an expensive article. In addition to two or three new plants from which the same or a similar substance may be derived, we now have an artificial substitute, which is practically unlimited in supply. The new substance is not quite so tough or elastic as gutta-percha, but it resists an equally high pressure at temperature, and is especially applicable as a perfect and durable insulator of wires for electrical purposes and for many other uses. It is prepared in the following manner:

A quantity of coal tar oil or equal parts of coal and wood tar oil, which is to constitute a third part of the whole mixture, is poured into a large kettle, together with an equal quantity of hemp oil, and is heated for several hours, either over steam or an open fire, to a temperature which lies between 252° and 258° Fahr. (it should not exceed the latter), until the mass becomes so ductile that it can be drawn in long threads, and the remaining third, consisting of a quantity of linseed oil, which has been thickened by boiling, is then added.

With this composition, from 5% to 10% of ozokerite and some spermaceti should be mixed. The mass is then again heated for some hours at the same temperature as above, and finally from 7% to 12% of sulphur is added. The mixture thus obtained is cast into forms, and treated the same as gutta-percha.

The proportions of the three oils may be slightly varied according to the practical purposes for which the composition is to be used.

CHEESE MADE FROM POTATOES.—A foreign paper says that cheese is made from potatoes in Thuringia and Saxony. After having collected a quantity of potatoes of good quality, giving the preference to a new white kind, they are holed in a caldron, and after becoming cool, they are reduced to a pulp, either by means of a grater or mortar. To five lbs. of this pulp, which ought to be as equal as possible, is added one pint of sour milk and the necessary quantities of salt. The whole is kneaded together, and the mixture covered up, and all is to lie for three or four days according to the season. At the end of this time it is kneaded anew, and the cheeses are placed in little baskets, when the superfluous moisture escapes. They are then allowed to dry in the shade, and placed in layers in large vessels, where they must remain for 15 days. The older these cheeses are, the more the quality improves. Three kinds are made. The first and most common is made as detailed above; the second, with four parts potatoes and two parts of curdled milk; third, with two parts of potatoes and four parts of cow or ewe milk. These cheese have this advantage over other kind—do not engender worms; and they keep fresh for a number of years, provided they are placed in a dry situation and in well-cleaned vessels.

AMBER VARNISH.—The following is an improved method of making this varnish: Take of white resin one lb., melt it in a clean glazed pipkin, then put with it two ounces of pale amber (finely powdered), little by little, stirring it with a small stick over a gentle fire until dissolved, and pouring in now and then a little oil of turpentine when you find it beginning to grow stiff; continue to do so till the amber is melted. Great care must be taken that you do not set it on fire, for the very vapor of turpentine will take fire by heat only; but if it should happen to get on fire, cover the vessel close with a flat board or wet blanket, and the air being kept from it, it will go out. It will be best to melt the resin in a cylindrical glass, in a bed of hot sand, after the glass has been well annealed or warmed by degrees in the sand bath, under which you must keep a gentle fire. When the varnish is made, pour it into a coarse linen bag, and press it between two hot boards of oak or iron.

SOLIDIFIED OIL.—A new article of manufacture has recently been introduced in England in the form of "solidified oil" for lubricating purposes. This new substance is said to possess some valuable and special characteristics. Although solid, the oil is soft and to a large extent unaffected by cold or heat. It does not become fluid until the temperature to which it is exposed reaches 212° F., the boiling point of water; and it can be made to reach a still higher melting point if required. It contains no acid, and leaves no deposit in steam cylinders. When passed into the feed water, through the exhaust pipe, it has the effect of preventing incrustation in steam boilers. It neither gums nor clogs on exposure to air or heat. It is applicable to all purposes where tallow can be used, and, weight for weight, will last four times as long and is three times as economical. It is said to possess considerable power of cohesion, which renders it peculiarly well fitted for perpendicular surfaces.

TO POLISH BRASS.—Pulverize a sufficient quantity of sal-ammoniac very finely and moisten it with soft water; rub the paste on the brass, which should be warmed meanwhile over some clear coals of wood; then rub dry with a soft leather, dusted with a mixture of bran and Spanish white. Another method is to wash the brass with a solution of one ounce of alum holed in a pint of strong wood-ash lye; when dry, polish with fine tripoli on a soft chamois leather.

HORSEHIDE BELT LACING.—A correspondent of the *American Machinist* describes a very durable belt lacing which was made as follows: A dry, untanned horsehide was soaked in water until soft enough to cut, and then cut into strips. These were made soft and pliable far sewing by "sawing" them over a square cornered iron. The belt was then sewed with the hair side inward the first time across, and outward on the finish, so that the hair took all the wear. After the strip had dried it was as solid as any hooks, with the advantage that it could not unhook. It wore remarkably well, and did not eat the belt holes.

NEW VARNISH.—Fr. Theis, of Biesendorf, prepares a varnish consisting of 100 parts of resin, 20 parts of crystallized carbonate of soda and 50 parts of water; by heating these substances together and mixing them with a solution of 24 parts of strong liquor ammonia in 250 parts of water. With the mass thus obtained the pigments are levigated without the addition of linseed oil or turpentine; the paint dries readily without the aid of a drier and looks very well, especially when varnished. The paint keeps well, even under water, and becomes very hard. The cost is said to be about one-third that of ordinary oil paints.

CHEAP PAINT.—Three hundred parts washed and sieved white sand, 40 parts of precipitated chalk, 50 parts of resin, and four parts of linseed oil are mixed and boiled in an iron kettle, and then one part of oxide of copper and one part of sulphuric acid are added. This mass is applied with an ordinary paint brush while warm. If too thick, it is diluted with linseed oil. This paint dries rapidly and gets very hard, but protects woodwork excellently.

NEW LUBRICANTS.—K. Drechsler mixes graphite thoroughly with the whites or yolks of eggs, dries the mixture, pulverizes it and scatters it upon the parts of machinery which move slowly. G. Lieckfeld mixes graphite with soluble glass, so as to make a stiff broth. The mass is spread upon worn surfaces, where it soon hardens and can be filed or turned, so as to restore the machinery to its original perfection.

## GOOD HEALTH.

## Remedy for Burns and Bee-Stings.

EDITORS PRESS:—Dry wheat flour, if applied immediately to a burn, relieves pain and prevents a blister forming.

Common fine salt dampened a little, and put upon the wound made by a bee stops pain and swelling immediately.—*Mrs. I. L. M.*

THE PHYSIOLOGY OF WALKING.—From a summary given by the London *Lancet* of the manner in which M. Marey has investigated some points in the physiology of walking, we extract: "Some time ago he devised an apparatus for registering the steps, which he has called an *odograph*. It consists of a small cylinder, rotating by means of clock-work in its interior; and of a pen which marks on the cylinder, and is raised at each step by an impulse communicated by a ball of air beneath the sole. Observations have been made on a number of soldiers. It was ascertained that the step is longer in going up hill than in going down hill. It is shorter when a burden is carried; longer with low than with high-heeled boots; longer when the sole is thick and prolonged a little beyond the foot, than when it is short and flexible. It thus appears that the heel may with benefit be almost indefinitely lowered; while it is disadvantageous to prolong the sole of the boot beyond a certain limit, or to give it an absolute rigidity. Some influences which lengthen the step lessen its frequency; so in going up hill, the step becomes at the same time longer and less frequent. In walking on level ground, the length of the step and its frequency are always proportioned; the quicker the walk the longer the step."

THE RESULT OF SWALLOWING TEETH.—A Miss Cole, of Middletown, Orange county, N. Y., on the 5th of January, 1869, swallowed a new set of false teeth, which became separated from the rubber mold in which they had been set while masticating her food. Before she could eject the food from her mouth the teeth had gone down into her stomach. The family physician was summoned, but all his efforts were unavailing. The teeth caused her no discomfort, and in a short time the matter was entirely forgotten. A few days ago, says the local paper, Miss Cole, the lady in question, felt a sharp pain near her left shoulder, and on examining the spot found what appeared like a wen under the skin. With the aid of a pen-knife she extracted a hard substance which proved to be a tooth. She was at a loss to know how the tooth came to be in such an unusual spot until she suddenly recollected that she had, 12 years ago, swallowed her set of teeth. During the past few days the lady has been cutting teeth all over her body, and had at last accounts recovered 12 of the 14 teeth that had formerly constituted her full set. She is anxiously awaiting the arrival of the other two. She has placed the teeth in a glass case, and will keep them as mementoes.

## Practical Knowledge.

This world little imagines how largely it is indebted to the laborious researches of scientific medical men for many of the most important truths relative to human health, happiness and life. As population increases, and the value of food is enhanced, the knowledge which chemistry has elicited is becoming more and more valuable in a practical point of view.

"How much ability to labor can I derive from eating a pound of potatoes, or a dollar's worth of brandy, beer or gin?" are items which could be turned to large account by multitudes of the toiling poor.

Some kinds of food are more nutritious than others, and if it should be found that articles which are cheapest, have most nutriment, and give the highest ability to labor, then knowledge becomes money to the poor. Tables vary, but some of the general results are as follows: One lb. of rice, prepared for the table, gives 88% of nutriment, and consequently, a relatively proportional ability to labor, compared with other articles of food. A pound of beef, costing 15 cents, gives only 26% of nutriment. According to these estimates, therefore, rice as an article of food, is 100% cheaper, 100% more valuable to the common laborer, than roast beef, yet countless numbers of the poor in New York strain a point daily to purchase beef at 15 cents a pound, when they could get a pound of rice for one-third of the amount, the rice, too, having three times as much nutriment as the beef, making a practical difference of 600%, aside from the fact that boiled rice is three times easier of digestion than roast beef, the rice being digested in about one hour, roast beef requiring three hours and a half. There is meaning, then, in the reputed fact, that two-fifths of the human family live mainly on rice. We compile, therefore, the following tables for preservation, as being practically and permanently useful. All the economist requires, is to compare the price of a pound of food, with the amount of nutriment which it affords.

TOBACCO SMOKING BY CHILDREN.—If we are willing to accept the opinions which sanitarians in other nations have formed, we have a very decided one ready to our hand in Switzerland. That intelligent republic enacted a law, last year, prohibiting the sale of tobacco to minors under 15 years of age, and making it an offense against the law for such to smoke. Hence a boy of 12 or 14 who parades the streets of Geneva or Berne with a cigar in his mouth is liable to be arrested and committed to the police station; and, as they have a disagreeable habit in that republic of enforcing the laws they enact, such would be pretty certain to be the juvenile smoker's fate. We recommend to our fellow countrymen their manner of dealing with the habit, which, whether harmless or not to most adults, is unquestionably of great injury to young boys.—*Med. and Surg. Reporter.*

HEALTHFULNESS OF BUTCHERS.—The proverbial freshness and healthfulness of butchers is well known and has been attributed to the fact that they absorb, by assimilation through the respiratory passages, the nutritive and vitalizing principles of the meat volatilized in the air, for it is a generally observed fact that butchers have small appetites and do not eat much meat. Assuming this to be the true explanation, it is argued that young people suffering from deficient or impure blood, and especially children of a weak or lymphatic constitution, might be subjected with advantage to hygienic treatment based upon it. A French physician of eminence commends the idea, and offers a plan for a kind of gaseous baths for patients, the air to be charged with vapors of the appropriate vitalizing principles, and thus, he thinks, arrest the progress of tuberculation.

SALICYLATE OF SODA IN RHEUMATISM.—In regard to the use of salicylate of soda in rheumatism, Dr. Bouloumie communicates to the Paris Academy of Medicine, some of the results of his recent investigations. His more important conclusions are, that it is in the case of young men—patients who have not before undergone attacks of gout, or who do not present any tendency to nervous depression—that the salicylate may be used without danger; second, that it acts chiefly by deadening pain; third, that in thus treating acute articular rheumatism in children the salicylate is perfectly well borne by them, even in a daily dose of six grams.

### TABLE OF CONTENTS.

**GENERAL EDITORIALS.**—The O'Hara Chloridizing Furnace, 273. Passing Events; Foundry Notes; California's Position; Precipitants for Gold, 280. The Brush Electric Light, 281.  
**ILLUSTRATIONS.**—Plan and Section of the O'Hara Furnace, 273. Brush Electric Light, 281.  
**CORRESPONDENCE.**—High Explosives—No. 4, 280.  
**MISCELLANEOUS.**—Copper Smelting—Its History and Processes—No. 3; The Cost of Amalgamating Ores in Utah and Nevada—No. 1; Railroad Horticulture, 274. Meeting of the Railroad Commission; North Columbia; Suggestions to Eastern Capitalists; The Two Mountains, New Mexico; The Mohave Mines, 278.  
**MECHANICAL PROGRESS.**—A Scientific Railway Car; Mechanical Quacks; Why Nuts Work Loose; Reduction of Cost in the Manufacture of Iron and Steel; Substitutes for Plated Metals, 275.  
**SCIENTIFIC PROGRESS.**—A Novel Theory; Microscopic Structures of Metals; Possible Revelations of the Microscope; Explosion of Bodies Under Electrical Forces; The Compass on Iron Ships; Phosphorescent Illumination, 275.  
**MINING STOCK MARKET.**—Sales at the San Francisco Stock Boards; Notices of Assessments, Meetings and Dividends, 276.  
**MINING SUMMARY** from the various counties of California, Arizona, Montana, Nevada, Oregon, Utah, Colorado, and Idaho, 276-77.  
**THE ENGINEER.**—The Future of American Railroads; Impromptu Ingenuity, 279.  
**USEFUL INFORMATION.**—A New Substitute for Rubber; Cheese Made from Potatoes; Amber Varnish; Solidified Oil; To Polish Brass; Horsehide Belt Lacing; New Varnish; Cheap Paint; New Lubricants, 279.  
**GOOD HEALTH.**—Remedy for Burns and Blisters; The Physiology of Walking; The Result of Swallowing Teeth; Practical Knowledge; Tobacco Smoking by Children; Healthfulness of Butchers; Salicylates of Soda in Rheumatism, 279.  
**NEWS IN BRIEF,** on page 284 and other pages.

#### Business Announcements.

To Chlorinators—C. H. Aaron, S. F.  
Wall Paper—Mackintosh & Co., S. F.

#### Passing Events.

Probably the most interesting item of mining news of the week is the strike in the Bald Mountain Extension claim at Forest City. They took over several hundred dollars worth of coarse gold where they struck the channel. It is said to be now the general opinion in the vicinity that the extension is really a part of the Old Luc Yankee lead, that yielded hundreds of thousands of dollars in dividends some years ago.

The trouble between the Mechanics' Union and the mining companies at Cherry Creek, White Pine county, has been settled. A public meeting being called, and a majority of the citizens voting that the Union was not justified in asking the raise of wages named by them, the Union acquiesced in that opinion, and all of them went back to work at the old rates. None of the men who participated in the strike were discharged. Everything is running as usual at the mines and mills.

The Richmond vs. Albion suit has been closed at Eureka, and the court has reserved the decision, which will be filed in writing before May 15th.

Parties are starting from every direction for Wood River. In all our exchanges we see notices of the departure of prospectors. In all probability the country will be crowded, as is usually the case where there is an excitement of this kind. Prospecting has begun and men are pushing their way into the hills as fast as the snow recedes. The tide of population is beginning to move from Bellevue to Ketchum. Ground is graded for a new smelter, and a water-ditch is being built. The companies along the river have begun work in earnest on their mines in many places. The great majority, however, will be compelled to wait a little longer before they can begin active operations. We hear of parties being made up for Alaska mines, some of them going up the coast in vessels of their own.

#### Foundry Notes.

##### Copper Furnaces.

A noticeable feature just now is the number of copper mines coming to the front, there being quite a stir in that metal at present. The utilization of smelting ores of other kinds is also noticeable. Several new districts in Arizona and the Wood River region, Idaho, where smelting ores abound, are attracting notice and furnace construction is looking up.

The Pacific Iron Works in this city are engaged in making a number of smelting furnaces, and having had large experience in that line, now make a type of furnace which is ready to put in use on arrival, no brick work being required.

They have just shipped a 30-ton copper furnace to the Huachuca Copper Co., in Silver Bell district, Arizona. Are now completing another 30-ton copper furnace for the Copper Queen, at Bisbee, Arizona, which mine has, by the way, been sold for \$1,200,000 within the past few weeks. This shows what a really good copper property is worth. The works are also making a 30-ton copper furnace for the Reward Co., at Genesee valley, Butte county.

They have lately shipped a Howell furnace and equipment for roasting mill, to the Ventanitas mining company of Mexico, and sent a furnace and drier to another Mexican mine near Alamos.

A shipment was made last week of a lot of machinery to the Etna mine, at Galena, Nevada, for refitting the mill. Refitting work is also being sent to Lewiston, Idaho. A number of settlers, amalgamating pans, etc., have been sent recently from these works to the Shielde mill, Colorado. Three sets of double hoisting works have been delivered to as many mines at Butte, Montana. Quite a number of these hoists are being built, of the type we recently illustrated in this journal.

##### Concentrators.

Millie B. Dodge has delivered several of his patent concentrators this month. Two of these have been sent to Oregon. Two more are in the hands of Mr. Eames, at Tuttle town, Tuolumne county. Two have been sent to Mr. M. H. Sunderland, at Coarse Gold Gulch, Fresno county. One has been sent to New York for use at the sampling works of Kunstel, Riotta and Mather. Mr. Hoffman, of this city, has also purchased one. These concentrators, as well as the Dodge rock breakers, are made under Mr. Dodge's personal supervision, at the Empire iron works. About a dozen of the rock breakers were shipped this month, and a number more are being made. The rock breaker is an old and well-tried implement, and the concentrator is also proving itself a practical and useful appliance.

#### California's Position.

An encouraging item of news is that to the effect that the Free Labor Exchange, of this city, will be closed this week, there being no longer necessity of maintaining it. The demand for labor is now about equal to the supply, and there is work for all who want it. This, in this city, where the railroads and steamship lines center, speaks well for the business of the interior, for it is from here the interior draws its laborers. The surplus population of the city seems to have gone away, probably being forced into channels of labor outside of the influences of the city.

Although we cannot say that many new manufacturing enterprises have of late been inaugurated in San Francisco, it is nevertheless the fact that most of those already established are in a flourishing condition. Within the past few weeks we have had occasion to call at a number of manufacturing establishments and in each case we have found preparations being made or under way for an increase of facilities. The proprietors all speak encouragingly of the future, and by no means have any fears of San Francisco losing her commercial prestige.

In the interior of this State, more especially in the mining region, matters look more encouraging than for many years. Numerous old mines are being opened again, and many new ones are being worked. There seems to be more of a general disposition to thrift than formerly. Miners getting hold of a claim work it legitimately for their own benefit, and do not squander their earnings as used to be the fashion. The agricultural regions of the State are also prosperous. In fact, none of us in California have any cause of complaint. We are favored with good climate and abundant natural resources ready for development. Somewhat extravagant notions imbibed from pioneer practices, and tricks of politicians, have made dull times for a while, but we are fast working out of this and will soon be fairly on our feet again. The change in the labor market is a first-rate sign of healthy commercial vigor.

A REPORT comes to us through a gentleman from Benton, says the *Emerald Herald*, that the superintendent of the Diana mine recently reduced the wages of miners at that mine from \$4 to \$3.50 and \$3 to \$2.50 for underground work and \$3 for top hands. There was talk among the miners of a strike.

It is proposed to add 40 stamps to the Father de Smet mill, making it 120 stamps.

#### High Explosives.

[Written expressly for the MINING AND SCIENTIFIC PRESS, by M. ESSLER, Chemist.]  
Number Four.

##### Nitro-Glycerine.

At G. M. Mowhrey's factory, near North Adams, in Massachusetts, the nitrication of the glycerine takes place in stoneware jars; 116 of these are distributed over nine wooden troughs, which latter are filled to within a few inches from the top of the jars with ice-cold water, or a mixture of ice and salt. Each jar receives 17 lbs. of acid mixture, and into this 1 lb. of glycerine is introduced, drop by drop, from glass vessels, which are placed on a shelf just above the acid jars. Below this shelf runs an iron tube, about 1½ inch diameter, through which cold, dry air is conducted; from this tube glass pipes branch off, joined by means of india rubber tubes, into each jar, which thus receives during the dropping of the glycerine, a constant current of cold air, acting both as cooler and as stirrer. Very beneficial influence is ascribed to this air current, which oxidizes also nitrous acid vapors.

The introduction of the glycerine into the acid must be finished within one and a half hour; there should be no rise of temperature, and certainly no appearance of red vapors. After the transformation of the glycerine, the jars are emptied into troughs containing water of 70° F.; the nitro-glycerine sinks to the bottom and remains covered with about six feet of water, for a quarter of an hour, when first the water is drawn off from above, then the nitro-glycerine from below. The latter is transferred to oscillating casks in which it is washed three times with water, and twice with soda solution, a current of air passing through the liquid all the time. The wash waters pass into a tub, from thence into two casks, sunk into the ground, where such nitro-glycerine as had been carried away by the water is retained. (The writer considers Mowhrey's plan very good and strongly recommends some of its features to the consideration of nitro-glycerine manufacturers.)

The nitro-glycerine is carried in copper vessels to a shed, about 100 yards distant, and poured into stoneware jars (the writer objects to the employment of stone, porcelain, or such like ware for handling made nitro-glycerine; he would recommend vessels of india rubber or paper, or something which does not break or leak), of 60 lbs. contents, and the jars placed in reservoirs filled with water of 70° F., and left here three days. Impurities rise to the surface, and are skimmed off.

The nitro-glycerine is now ready for commerce. It is filled in canisters of galvanized sheet iron, coated inside with paraffine and capable of holding 56 lbs.; the floor of the shed where the filling takes place is covered with a thick layer of calcined plaster of Paris, in order that any spilled nitro-glycerine be absorbed at once. The canisters are then exposed to the cold of ice and salt for the sake of freezing their contents; in this state they are stored, 30 to 40 to a hatch, in magazines at least 100 yards from all the other buildings of the factory. The transport of this nitro-glycerine takes place also while it is frozen.

As the liquid nitro-glycerine does not enter to any extent into practical use on this coast, I will simply mention some of its

##### Properties.

Nitro-glycerine is an organic poison. It produces serious consequences when taken into the system—vertigo, weakening of sight, stupor, pains in the cardiac regions; in larger doses it acts like strychnine, being fatal when more than 10 grams are swallowed. Even mere contact with the skin produces serious symptoms, though workmen get used to it after a time. In external contact, the nitro-glycerine may be of serious consequences if it is taken into the blood; so workmen, if they have sores or wounds on their hands, must be extremely cautious in handling it.

At ordinary temperatures it is an oily liquid, clear, colorless or yellowish, refracting light, of sweetish and burning taste, without odor, of 1.6 specific gravity; it solidifies at a comparatively high temperature, 40° F. In water it is insoluble, but dissolves easily in ether, wood spirit, benzole, chloroform and hot alcohol.

Pure nitro-glycerine does not decompose spontaneously at ordinary temperatures; up to 120° F. its loss is hardly perceptible by evaporation; by gradual heating in enclosed vessels up to 212° F. it can be kept in that state for several days without explosion; if the heating is continued gradually and slowly up to 400° F. it commences to decompose and loses its explosive properties. A sudden and quick heating to 330° F. will explode it. The gases resulting from the explosion are: carbonic acid, water vapors, nitrogen and oxygen and combinations of the latter two elements.

Theoretically the explosive force of nitro-glycerine as compared with gun powder is stated to be as 1 to 10, but in practice this figure is much lower and different experimenters give different opinions. Putting a light directly to nitro-glycerine does not lead to detonation, but it is very dangerous to set fire to it, as in bulk the fire may heat the mass to its exploding temperature and lead to disastrous results. Some writers assert there is no danger if any amount of nitro-glycerine is set on fire; they say it will burn away quietly long before it is heated to the degree at which it explodes.

If heated in a closed space it explodes violently.

If it is exposed for some time to a strong heat, like in a tropical climate, it becomes very sensitive, owing to a partial decomposition; then any concussion, increase of temperature, or strong vibration in the air will explode it.

Electricity will explode it. By putting the two poles of an electric battery into the fluid and passing the sparks between them for some seconds, the surface of the nitro-glycerine becomes agitated, turns black, and then it explodes.

Mr. Ahel says: That nitro-glycerine explodes by electricity or any other influence which produces heat; only then, when the intensity of the same or the time during which the same acts, is sufficient to produce a decomposition of a portion of the liquid, and if this decomposition has once commenced, the temperature rises by accumulation of heat to such a point as to cause its explosion.

Nitro-glycerine explodes by a blow or concussion, but gradually increasing pressure is unable to explode the liquid, but if a blow is given to it with sufficient vehemence and quickness, so that the force of the stroke will produce a sufficient heating point, then the particles struck will explode.

At about 32° F., nitro-glycerine becomes solid, and when exposed to that temperature for some time it becomes a hard substance. In this condition it is hard to explode, even with the fulminates (caps). Although in a frozen condition this substance is considered much safer than in its liquid state, it has still to be treated with due precaution.

Several accidents are on record where, in Europe, the frozen stuff was broken with a pick, and these accidents have proven that, although frozen nitro-glycerine is hard to explode with a cap, it will nevertheless explode easily when struck heavily with a sharp-pointed instrument. For instance, take a pick with a sharp point of 10 lbs. weight and strike it against a hard rock with a velocity of 20 ft. per second, and if there is any nitro-glycerine at the point of contact, this blow will exceed by far in intensity the concussion produced by an exploding triple-force cap and consequently detonate the nitro-glycerine.

#### Precipitants for Gold.

In the leaching of ores, when the ore contains copper, Mr. Aaron says the waste solution from the tanks in which the copper is precipitated can be used for refilling the vat containing the precipitant for gold, as it contains a large quantity of iron proto-salts, chloride and sulphate. The strength must be reinforced with copperas, or acid and iron. The waste liquor from the chlorine generator, consisting partly of manganese proto-sulphate, is also a good precipitant for gold. In order to utilize as much as possible of the chlorine which it contains, as well as any free acid which may be present, it should be placed in a covered tub, or small vat, with some scrap iron. In a day or two the chlorine and the acid will be saturated with iron, thus forming an additional quantity of precipitant.

Other precipitants which yield the gold in the metallic state are, oxalic acid, sulphurous acid, the antimony, arsenic, and copper lower chlorides, and animal charcoal. The latter is used as a filter on which the gold solution is poured, when the particles of carbon become covered with a film of gold. It is patented. In some European works the gold is, or was, thrown down as a sulphide, by means of hydrogen sulphide. This method has the disadvantage of precipitating also copper and some other metals if present.

**BRITISH COLUMBIA MINES.**—The *Colonist* correspondent at Takou, B. C., writes despairingly from the new mines. He says the excitement about the Takou mine is gradually subsiding, and none of the old miners have much confidence in it. About 70 or 80 men are reported to be on the spot, but as the ice has not yet got out of the ground, very little has been done. The quartz-bearing vein is said to be very thin; and as it is not expected that surface diggings will be found, there is little or no inducement for single men without capital to visit that far-off place. Several traders and miners have taken up claims at Takou, intending to resume their business there. The present aspect of things, however, is not sufficiently encouraging for them to do so for a time; therefore they will remain at Vangor or return to their old locations at Cassiar.

**SUGGESTIVE.**—We take the following from the *Placer Miner* of the 21st: We are informed there is a disappointment in the Dewey mine with the Chinese miners. They do not seem to understand drift mining as well as was thought, and it now takes three Chinamen to do the work of one good white miner, comparatively. The Dewey people seriously contemplate discharging the Chinamen and putting on white men again, so we understand. It will be remembered about six weeks ago some 30 white men were discharged and Chinamen put to work in their place in this mine. We suggested then it was a bad policy.

**WATER** for Candelaria is to be conducted from the White mountains, a distance of 23 miles. At present the dwellers in this camp pay 25 cents per gallon for drinking water, strongly impregnated with alkali. It costs \$2 to take a bath.

## The Brush Electric Light.

That the electric light is to be the principal illuminator in the future, few doubt. For street lighting purposes and for large manufacturing establishments it is particularly useful and is rapidly growing in favor. On this coast it is being introduced into quartz mills and among the hydraulic mines, and is daily attracting more and more attention. For this reason we feel sure our readers will be interested in the following description of the Brush electric lighting system, which we take from the *Scientific American*: The most difficult problems in electric lighting have been: (1). To provide an efficient and economical means of converting mechanical power into electric energy, that is, a good dynamo-electric machine. (2). To devise a generator able to evolve an electric current capable of subdivision, to supply a series of lamps in one circuit. (3). To invent a self-regulating lamp, adapted to such an electric circuit, and so constructed that any accidental disturbance of it, or its extinction, would have no effect upon the other lamps in the same circuit. The lamp to be at the same time easy to keep in order, durable and economical in power. (4). To discover an automatic method of regulating the supply of electricity so that the current would be always exactly equal to the varying requirements of the circuit. Up to 1876, when Mr. Brush produced his first dynamo-electric machine, a large number of scientific investigators and mechanical inventors had been at work upon these problems. Individually and together they had accomplished much, but there was yet no machine that could be considered a commercial success, and no lamp—certainly no system of electric lighting—that had passed beyond an experimentally promising stage. There was no machine that could furnish a current for a number of lamps, much less sustain them in one circuit with steadiness and uniformity. Very soon after Mr. Brush entered the field, he presented to the public an apparatus which was free from the defects of all other systems, and the public, waiting for just such an apparatus, welcomed the new machine, and the result is that to-day the Brush Electric Light is practically the sole occupant of the field; at least 49 out of every 50 lights that have been sold in this country being Brush lights. Up to the present time over 6,000 Brush lights have been sold for regular industrial use, and the business has only just opened. An idea of the great superiority of the Brush system of lighting may be obtained from the fact that with the largest sized Brush machine 40 powerful electric lights are burned in one circuit, with an absorption in the machine of 36 horse-power. We believe that no other system of lighting can maintain one-fifth this number of lights on one circuit; and most are confined to a single light to one machine. The genius of the inventor of this system, and the energy and good business management of the Brush Light Electric Company, of Cleveland, have done more since 1876 to place the business of illumination by the electric light upon a practical and substantial basis than has been done in this direction by all other inventors since the discovery by Faraday, at least so far as voltaic arc lights are concerned.

In every sense the Brush electric light is a practical, commercial success, and is no longer an experiment. No better proof of this could be required than the well known fact that no one can buy a Brush machine or lamp at less than regular prices. Makers of other machines may offer inducements of every kind, in the way of large discounts from regular prices, the privilege of a trial with no obligation to purchase, long deferred payments, etc.; but the Brush Company takes the same ground held by George H. Corliss in regard to engines, and claims that the apparatus they furnish is no longer experimental, that it is well worth the price asked for it, and should not be compared with merely experimental systems whose principal recommendations are that they can be bought at the purchaser's own price, and may be returned if not satisfactory.

Not only has the Brush light practically monopolized the field in this country, but, if we may judge from reports, it is also rapidly doing the same abroad. It has made wonderful advances in England, where it is controlled by the Anglo-American Brush Electric Light Corporation, (limited), having a capital of \$4,000,000. One year ago this company bought the English patents of Mr. Brush at a very large price, and

we understand they have recently purchased all his other foreign patents—those for France, Belgium, Austria, Russia, Italy, Spain, Norway, Sweden, Denmark, etc., paying for them still larger prices than they paid for the English patents, and they now propose to commence the introduction of the Brush light into all these countries in the same business-like and thorough manner which has characterized its management from the first. The sums paid for these foreign patents are, it is claimed, greater than have ever been paid for any other foreign patents obtained by an American. As rapidly as arrangements can be made the Brush light is being introduced into every civilized country on the globe, and it seems to have found a field in almost every branch of industry, and in almost every imaginable situation, as the following

out changing its speed or adjusting the lamps. Each lamp of the Brush type is provided with an automatic cut-out, which is one of the valuable features of the system. If a lamp in circuit becomes deranged so that its carbons do not feed together properly, or if the carbons need renewing, the cut-out mechanism is called into action and this particular lamp is switched out of circuit without disturbing any other lamp in use. When this lamp has been supplied with carbons again and put in order it will burn as before. This simple cut-out mechanism effectually guards against all the dangers of general extinction of lights, a thing liable to occur in all other systems. We believe that no other system uses a cut-out.

When it becomes desirable to operate lamps more than seven or eight hours continuously,

1. Double Lamp, 2. Carbons, 3. Single Lamp, 4. Focusing Lamp, 5. Head-light Lamp, 6. Dial Attachment, 7. Ornamental Lamp.

## BRUSH ELECTRIC LAMPS.

partial list of users indicates: There are 800 lights in rolling mills, steel works, shops, etc.; 1,240 lights in woolen, cotton, linen, silk and other factories; 425 lights in largest stores, hotels, churches, etc.; 250 lights in parks, docks and summer resorts; 275 lights in railroad depots and shops; 150 lights in mines, smelting works, etc.; 380 lights in factories and establishments of various kinds; 1,500 lights in lighting stations, for city lighting, etc.; 1,200 lights in

the double lamp shown in our illustration is used, and two sets of carbons are employed. Both carbon rods are actuated by a single magnet, the same as that employed in a single lamp, and they are so arranged that when one set of carbons is completely consumed, the other set is automatically switched into circuit. In practice the transfer of the voltaic arc from one set of carbons to the other is instantaneous and scarcely noticeable. By means of these

## BRUSH DYNAMO-ELECTRIC MACHINE.

England and other foreign countries. A total of over 6,000 lights which are actually sold, none of them being on trial.

This system, we believe, is the only one by which a large number of powerful electric lights can be burned in series, upon a single circuit of wire, with steadiness and uniformity. The machine known as No. 8 maintains 40 lights of 2,000 candle power each, upon a circuit 10 miles in length of copper wire No. 6, English gauge. By using still larger wire the distance or length of the circuit may be proportionately increased, it being possible to extend the circuit to 25 miles by using No. 1 wire. The smaller sizes of Brush machines are fully as efficient. A No. 7 machine is used in Montreal to light the harbor on a circuit of about three miles, using 16 lights. Another peculiarity and advantage possessed by the system is that any number of lights desired, from one up to the number capable of being maintained by the machine, can be burned in circuit from the machine with-

double lamps a system of lights may be maintained in continuous operation from 14 to 16 hours without requiring any attention, whereas other systems are limited to six or eight hours' continuous burning.

The great simplicity and durability of the machines are points of importance in considering the wear and tear from constant use. The experience of the four years shows that 1% allowance for wear and tear is ample to cover, and that with even a less amount annually spent upon the machines they will last indefinitely. The engravings show the generator and the various styles of lamp.

The business of the Brush light on Manhattan island is in the hands of the Brush Electric Illuminating Company of New York, a corporation organized under the laws of the State, with a capital of \$1,000,000. The officers are: W. L. Strong, President; A. D. Juilliard, Vice President; A. A. Hayes, Jr., Secretary; S. B. Sturges, Treasurer; C. M. Rowley, General

Manager; R. J. Sheehy, Superintendent. The first lighting station of the company is at Nos. 133 and 135 West 25th street. It contains at present five dynamo-electric machines, the largest of which is 89 inches long, 28 inches wide, and 36 inches in height, and weighs 4,800 pounds, and runs at a speed of about 700 revolutions per minute. It is believed to be the largest machine in the world. Forty lights are fed by it, and it requires 36 horse power. Several circuits are connected with this station, one exclusively for lighting parks and streets, Broadway, from 14th to 34th street, is lighted from there. Among buildings in this district are the Sixth Avenue Elevated railroad, the Sturtevant House, the Gilecy House, the Standard Theater, Daly's Theater, the Bijou Theater, the Aquarium, Aherle's Theater, Koster & Bial's, the *Herald* office, and many others. The company runs wires from this station to any point within a radius of two miles, putting up the light in any desired place, and renting in the same manner as is done with gas.

The street lighting is done by means of double lamps on iron posts 20 feet in height, and in plain glass globes. It is proposed to extend this materially and to use the larger lights, elevated on poles, for open spaces, as is now done in the West. This company has had much success in lighting large buildings for halls, such as the Academy of Music, Madison Square Garden, etc., using opal and lemon colored globes, giving a hue to the light which is approved by the fair sex. The establishment of lighting stations in cities and towns for the illumination of streets, parks, open spaces, depots, docks, stores, factories, etc., is enlisting very large amounts of capital, and promises to be a business as profitable and as eagerly sought after by capitalists as gas companies have been heretofore. Companies have already been formed, or are about to be formed, for the establishment of such lighting stations in the following cities

and towns: New York, Philadelphia, Boston, Baltimore, Washington, Providence, Albany, Hartford, New Haven, Meriden, Rochester, Buffalo, Cleveland, Cincinnati, Dayton, Indianapolis, Columbus, Middletown, Detroit, Grand Rapids, Chicago, St. Louis, Denver, Salt Lake City, Ogden, Butte, San Francisco, etc. It is only a question of a few months before similar companies will be formed, and similar lighting stations established in every city and town of any pretensions in the country. In all the above places the Brush light is to be exclusively used.

The general plan of operations in all these lighting stations will be similar to the one in New York, which, briefly described, is as follows: A location is first selected, as central as possible with reference to the territory to be lighted; sufficient space must be provided for engines, boilers, heater, pumps, shafting, belt-pulleys, etc.; space is also to be provided for dynamo-electric machines with the necessary wires and connections. As the steadiness and quality of the light are dependent entirely upon the steadiness of the power, care is taken to provide for this by the use of engines of approved make, with automatic cut-offs and other modern appliances for producing steady motion. The central station having been thus equipped, copper conducting wires are run from it on poles, on house tops, or underground, to the various points or places where light is needed.

The light is furnished and charged for in proportion to the amount used, and this is readily ascertained by noting the consumption of carbons in the lamps, which is sufficiently uniform for this purpose.

When the engines in the lighting stations are started, the electric light machines are put in motion, and the electricity passes over the wires and produces a light in each lamp in circuit. An automatic governor or regulator is provided for each electric machine, and this is so constructed and so connected to the machine that, without changing the speed of the machine, any number of lights from one up to the number capable of being produced by the machine may be burned without any disturbance or interference, either in the machine or in the lamps. By means of this simple and admirable contrivance, any of the lamps in circuit may be turned off or turned on without increasing or diminishing the light in any of the other lamps in the circuit. From this description it will be evident that a lighting station of this character affords practically, all the facilities provided in the use of gas, for the electric lamp may be turned on and off at

(CONTINUED ON PAGE 284.)

HOME PRODUCTION.

HOME MANUFACTURE.

## BERKELEY LUBRICATING OIL WORKS, BERKELEY, CALIFORNIA.

Manufacturers of Machinery and Lubricating Oils, White Wool Oils, Leather Oils and Compounds  
**RAILROADS, STEAMSHIPS AND MILLS SUPPLIED AT REDUCED RATES.**  
 Our oils are produced under a new process, and guaranteed to be Superior to any oils in the Market.

**A. C. DIETZ & CO., Proprietors.**

Office and Salesroom, No. 9 Front Street, near Market, San Francisco.

IMPORTERS AND DEALERS IN

**PAINTS, OILS, WHITE LEAD, VARNISHES  
AND LAMP STOCK.**

### MOREY & SPERRY,

MANUFACTURERS OF

Gold and Silver Grinding and Amalgamating Machinery

**HOWLAND'S PULVERIZER** Takes the Place of the Cumber-  
some Stamp Mill and can be put up in one day ready for work.

IT HAS BEEN FULLY PROVED AND TESTED.

It weighs complete, 7,000 pounds. It costs \$1,500 ready for the belt. Will crush one  
1/2 hour of hard quartz that will pass through a 40-mesh screen. The wear is less  
1 in the stamp mill. Its wearing parts are plain castings and can be dropped into  
position in a few moments, as shown by the letters A, B and C, no  
bolts or keys are required; it can be set upon the floor of a mill  
with no expense for foundations, and can be used to crush and  
work in charges or continuous. It will amalgamate either gold or  
silver ores, making a simple, cheap and effective mill, it requires  
twelve-horse power.

Stamp Mills' Rock Breakers, Crushing Rolls, Amalgamating  
Pans and Separators for Gold and Silver Ores, Chlori-  
dizing Furnaces, Retorts, Rock Drills, Air Com-  
pressors, Steel Shoes and Dies for Stamps, and every  
description of Mine and Mill Supp. Iron Work  
complete for Wood Frames, also

**SPERRY'S  
WROUGHT IRON FRAME  
FOR STAMP MILLS.**

Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to  
put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores.  
Wet or Dry Crushing Mortars.

**MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.**

### LEFFEL'S IMPROVED WATER WHEEL.

PRICES REDUCED!

PATENTS REISSUED 1868.

The "OLD RELIABLE" with improvements, making it

**THE MOST PERFECT TURBINE NOW IN USE.**

Comprising the **Largest** and the **Smallest** Wheels, under both the **Highest**  
and **Lowest** head used in this country. Our new Illustrated Book sent free to  
those owning water power.

Those improving water power should not fail to write us for **New Prices**,  
before buying elsewhere. New Shops and New Machinery are provided for making  
this Wheel. Address

**JAMES LEFFEL & CO., Springfield, Ohio,  
and 110 Liberty St., N. Y. City.**

**ASSAYERS' MATERIALS,**  
MINE and MILL SUPPLIES,

**CHEMICAL APPARATUS AND CHEMICALS, DRUG-  
GISTS' GLASSWARE AND SUNDRIES, Etc.**

118 and 120 Market Street, and 15 and 17  
California St., San Francisco.

We would call the attention of Assayers, Chemists,  
Mining Companies, Milling Companies, Prospectors, etc.,  
to our full stock of Balances, Furnaces, Muffles, Crucibles,  
Spirifers, etc., including, also, a full stock of  
Chemicals.

Having been engaged in furnishing these supplies since  
the first discovery of mines on the Pacific Coast, we feel  
confident from our experience we can well suit the demand  
for these goods both as to quality and price. Our  
New Illustrated Catalogue, with prices, will be sent on  
application.

Our Gold and Silver Tables, showing the value per  
ounce Troy at different degrees of fineness, and valuable  
tables for computation of assays in grains and grammes,  
will be sent free upon application. Agents for the Patent  
Plumbago Crucible Co., London, England.

## The O'Harra Chloridizing Furnace.

(CONTINUED FROM PAGE 273.)

hours in passing through the furnace, according to its character. Only one man is required to attend the fires, no other attention being necessary, as the ore may be fed to the hopper from the battery by any mechanical means.

By the peculiar construction of this furnace the inventor is enabled to feed and discharge the ore at the same end of the furnace. The battery and machinery being at this end of the furnace, the ore may be elevated and passed to the amalgamating appliances with very little trouble or expense of handling.

Two of these furnaces are in use at Potter & Hall's mill, Copper City, Cal., one for drying and one for chloridizing. The ore is of a very base nature, consisting of sulphide of copper, iron, antimony and other base metals. The average battery assays about \$16 per ton. By the use of the furnace they roast and mill from 40 to 45 tons per day, and obtain from 90% to 95% of the assay value. This is attested by the mill owners. About 40 tons a day are worked. The furnace costs very little for repairs. Both furnaces give entire satisfaction and do the work intended as near as any furnace can do.

At the Isabella mine, Silver Mountain, Alpine county, Cal., it roasts and chloridizes antimonial and arsenical sulphurets of silver from 84% up to 95% of assay. At the Washoe and Ophir tailings company's mill, Ophir, Washoe county, Nevada, a furnace of this style roasts the ore at a cost of \$1.50 per ton.

Those desirous of further information concerning this furnace may obtain it by addressing H. F. Whitney at Ophir, Washoe county, Nevada.

## Recent Decisions Relating to Patents, etc.

We give below brief abstracts of decisions rendered upon patent cases in litigation, for the benefit of our readers:

## DECISIONS OF THE U. S. COURTS.

## Tilghman vs. Proctor, et al.

Supreme Court of the United States.  
1. A patent for a process, irrespective of the particular mode or form of apparatus for carrying it into effect, is admissible under the laws of the United States.

2. To sustain a patent for a process the patentee should be the first and original inventor of the process, should claim it in his patent, and, if the means of carrying it out are not obvious to an ordinary mechanic skilled in the art, his specification should describe some mode of carrying it out which will produce a useful result.

3. If a subsequent inventor discover a new mode of carrying out a patented process, though he may have a patent for such a mode, he will not be entitled to use the process without the consent of the patentee thereof.

4. The decision in *Mitchell vs. Tilghman* (19 Wall, 237) reviewed and overruled, and *Tilghman's* patent, relating to the manufacture of fat acids, sustained as a patent for a process.

5. The decision in *O'Reilly vs. Morse* (15 How., 62), and in the case of *Nelson's* patent for the hot blast (Webster's report), commented upon and explained.

## Wicko, Appellant, vs. Ortrum.

Supreme Court of the United States.  
1. Elements which are well known in other connections may form a novel combination when brought together in a machine to produce a new result.

2. When the arrangement of the machine is such that the combination of all its several elements, or their mechanical equivalent, is necessary to its successful operation, claims to a limited number of these elements should fairly be construed to include the rest.

3. A claim for a combination is not infringed by the use of a limited number of its elements.

\* More complete reports of the proceedings may be found on file in the office of the MINING AND SCIENTIFIC PRESS Patent Agency, 202 Sansome street, S. F.

**A SINGULAR DISCOVERY.**—From Mr. George Madeira, who came over from La Porte, the *Pinmas National* learns that the miners running the pipes in the Gold Gravel or Conly claims, washed out, last Monday, a small coffin, containing the body of an infant, supposed by the physicians to be about seven months old. The body was in an air-tight tin coffin, enclosed in a wooden coffin, and had evidently been buried with care, and for the purpose of removal at some future time. The tin coffin had been filled with alcohol, and the body was in a splendid state of preservation and as natural as when alive. The top of the coffin was knocked off by the pipe and lost in the water, and the tin box looked as though it had been buried some 20 years. No one in La Porte, even among the oldest settlers, can remember anything regarding it. The ground is what was formerly known as "Aristocracy Ridge." The tin box was again filled with alcohol, soldered up and placed in a wooden box, when it was buried in the graveyard. If our exchanges copy this item it may catch the eye of some one interested in the matter, or one who can clear up the mystery surrounding it.

The liquefaction of ozone has recently been effected by M. P. Hautefeuille and J. Chappuis. The fluid is of a beautiful blue color. The liquefaction was accomplished by subjecting a mixture of oxygen and ozone to pressure at a temperature of -23° to -25°, the ozone remaining liquid at 10 atmospheres pressure. The experiment needs to be performed with great care, owing to the liability of the ozone to change into oxygen with evolution of heat and explosive violence. The beautiful blue of this substance has led to the hypothesis that the color of the atmosphere at great depths may be due to the presence of ozone.

The Providence mine, Nevada county, will soon have its 20-stamp mill increased to 60 stamps. A new shaft will be sunk and new hoisting works put up.

## The Brush Electric Light.

(CONTINUED FROM PAGE 281.)

the lamp itself, as readily as if it were a gas burner. The lighting of interior spaces is in this way fully provided for in a practical manner.

In the matter of lighting streets and open spaces electric light possesses many advantages not possessed by any other illuminating agent. The electric lamps can be placed on top of lamp posts of moderate height, as in the lighting of Broadway, New York, each electric light providing for the illumination of a space 200 to 300 ft. in diameter; or the lamps may be placed upon towers at a considerable elevation above the ground and above adjoining buildings, as is done in Washash, Indiana, and Akron, Ohio; each light, or group of lights, providing for a general illumination over an area a mile or more in diameter. Either of these plans is perfectly practical and successful, and both have been thoroughly tested. For the lighting of cities and towns of moderate size the latter plan is the more economical, and will, no doubt, be very largely adopted. The town of Washash, Indiana, was the first in the world to light its streets wholly in this way, and they find that four Brush lights of 3,000 candle-power each, placed on an iron flag-staff on the dome of their court house, at a height of about 130 ft. above the ground, are sufficient for the general illumination of an area from one-half to three-quarters of a mile in every direction. Some of the streets although they are not nearer to the lights, because the light is not intercepted by intervening buildings. It is stated, however, that even in the streets where no direct light falls, and where the shadows are greatest, there is yet enough diffused light to permit of getting around without the use of other light. It is also stated that even at a distance of two miles from the lights there is a sort of general illumination produced, which is of considerable value.

By placing a sufficient number of powerful electric lights upon towers high enough, it is no doubt possible to produce an amount of light that would be practically as efficient as daylight for the lighting of all spaces within a reasonable distance of such towers. A sufficient amount of light could be thus provided to light the interior of buildings and dwellings sufficiently for ordinary purposes. This is the plan that has been proposed for the lighting of the Capitol and its surroundings at Washington.

It is proposed to place upon the dome of the Capitol, and upon six towers surrounding it, at a distance of 1,000 ft. from it, no less than 450 electric lights, each of 6,000 candle power, or a total light of 2,700,000 candle power, equal to 200,000 4-ft. gas burners. The effect of such an enormous massing of light at such a distance above the ground and surrounding buildings would produce a surprising effect, and within a considerable area would, no doubt, be practically equal to daylight. If this plan is carried out the Brush light will be used. This subject will be brought to the attention of the next session of Congress.

The officers of the Brush Electric Company (the home company) of Cleveland, Ohio, are as follows: Gen. Mortimer D. Leggett, President, (formerly Commissioner of Patents); George W. Stockly, Vice-President, Treasurer and Business Manager; F. K. Collins, Secretary; Nathan S. Possons, Superintendent; W. J. Possons, Assistant Superintendent.

Agencies for the sale of apparatus and appliances have been established in all sections of the country. The most important of these are the Brush Electric Light Co., of New York, the Brush Electric Light Co. of New England, and other companies under similar names at Philadelphia, Washington, Baltimore, Pittsburgh, Cincinnati, Chicago, St. Louis, Denver, Salt Lake and San Francisco. The officers of the California Electric Light Co., representing the Brush patents for the Pacific coast, are: William Kerr, President; P. B. Cornwall, Vice-President and Treasurer; George H. Roe, Secretary and Business Manager, with offices at 119 O'Farrell St.

**THE PRESS.**—Anybody who is interested in mines anywhere on this coast, and who is not a subscriber of the MINING AND SCIENTIFIC PRESS, fails to keep posted as he ought. We gather the news from all points, and in addition to this, keep track of all new mining and metallurgical appliances and processes as they come to the front. The PRESS will be found in the miner's cabin in every camp on this coast. It is the oldest of the mining journals, and has steadily promoted the interests of legitimate mining for upwards of 20 years.

The trouble between the Mechanics' Union and the mining companies at Cherry Creek, White Pine county, have been settled. A public meeting being called, and the majority of citizens voting that the Union was not justified in demanding the advance of wages named by them, the Union acquiesced in that opinion and all of them went back to work at the old rates. None of the men who participated in the strike were discharged. Everything is running as usual at the mines and mills.

And now comes San Bernardino, and claims that nothing is wanted to make it the richest mining county in the State but capital.

ANTIMONY is selling in Liverpool at £62 to £64 per ton for French Star Regulus.

QUICKSILVER in England is £6 10s per flask.

## News in Brief.

JAMES T. FIELDS, author and publisher, of Boston, is dead.

THEATRICAL performances are now prohibited in Cincinnati on Sundays.

MANY ranchmen have been driven into Fort Buford by hands of hostiles.

JAY GOULD is working to get control of the Southwestern system of railroads.

SINCE the 1st of February one nursery near Bakerville, Kern county, has shipped 120,000 eucalyptus and acacia trees.

The item of \$12,000 for salary of State Engineer Hall, has been struck from the general appropriation bill.

MRS. DEMENT, an emigrant's wife, and two of her children were burned to death by a forest fire in Arkansas while camped on a mountain.

A DEPOSIT of mammoth bones has been found near Yakima City. They are pronounced to be the relics of an extinct species of elephant.

A LARGE number of Polish and Russian emigrants, who arrived at New York on a steamer infected with smallpox, resisted all attempts to vaccinate them.

In answer to an advertisement for 35 men to go to the Arctic in the *Mary and Helen* in search of the *Jeannette*, upwards of 100 able-bodied men made application.

A LONDON despatch says the Governor of Cape Colony telegraphs that the Basuto Chief is willing to accept arbitration, his people meanwhile returning home.

MINISTER KASSON thinks that Austria and Hungary placed an embargo on American hog products more as a measure of protection than from sanitary considerations.

A private letter from the attorney of the Mussel Slough settlers at Washington, expressed hopes of a favorable hearing of the proposed pardon before the new President.

THERE are 127 small-pox and 107 typhus fever patients on Blackwell's Island, New York. During the week there were 33 new cases of small-pox and 37 of typhus fever.

It is stated that proposals will be made in Parliament for the erection of a national monument in Westminster Abbey to record the name and services of Lord Beaconsfield.

CHINESE sailors are being shipped on wheat ships from this port, white sailors being very scarce. The Chinese get \$25 per month and board, with three months' pay in advance.

The agitation in Greece is increasing. The Greek note this week will call the attention of the Powers to the fact that they have not replied to the reservations demanded by the former Greek note.

ADVICES from Tunis state that the Sultan has approved all the measures the Bey has lately adopted and negotiations have been opened with the Powers to protect the rights of both the Sultan and the Bey.

The leaders of the Oklahoma invasion are attempting to utilize the freedmen in gaining a foothold in the Indian Territory. The Commissioner-General of the Land Office pronounces the attempt illegal.

FLORIDA oranges have been successfully imported into England, a recent experiment demonstrating that the fruit arrived in excellent condition. The enterprise is very favorably regarded in England.

H. E. Davis, principal owner of the South Pacific Coast railroad, denies that that road has been sold to the Atchison, Topeka and Santa Fe, the Atlantic and Pacific, or any other road, or to any person or persons.

It is said that the Kern Valley Canal Company have commenced, or are about to commence, the extension of their canal to Tulare lake, with a view of completing a continuous line of water communication to San Francisco.

AN agitation in favor of the immediate abolishment of Cuban slavery has been begun in Spain. JEREMIAH HODNETT, Chairman of the Ballydehob Land League, has been arrested in Ireland under the Coercion Act.

A FEW days since Willie Barr, a child 5 years of age, who lives at Olympia, was butted in the face by a sheep. The little fellow was struck on the right cheek, and his jaw was broken in the center so that one half of it fell down.

A LONDON despatch says: In order to repress an attempt by the Algerian army to take advantage of the Tunisian difficulty for revolt, France has decided to send considerable reinforcements there. It is stated that 50,000 troops will go.

A BERLIN despatch says: Another audacious circular addressed to the Czar has been issued by the Nihilists, pointing out that the indiscriminate execution of those concerned in the assassination of Alexander II only served to strengthen the ranks of the Nihilists by driving many lukewarm persons into the extreme faction of the party.

BRADY, the deposed Assistant Postmaster-General, has written a long letter of denial to the New York *Herald* of the charges made against him while at the head of the Contract department of the Post Office Department. He claims that Congress is responsible for the increased cost of the Star routes, and demands an early investigation.

It is rumored in St. Louis that a sale has been effected of a majority of the stock of the International and Great Northern railroad to a combination of New York capitalists, of which Jay Gould is the head. This will consolidate under one management the Missouri Pacific, the Missouri, Kansas and Texas, the Texas and Pacific and the International and Northern roads.

**COPPER.**—Quotations of copper in Liverpool are: Good ordinary brands, £61 to £61 5s per ton; ore, 12s 6d and Regulus 12s 9d per unit. The market in Liverpool is in a stagnant condition. Although supplies have been reduced, speculation in this metal is dormant. The total visible supply is 2,149 tons less than a month ago, and 3,625 tons less than a year ago. Chile exports to the end of March equal 10,048 tons fine. Stocks of West Coast prodnce equal 32,391 tons fine.

CHRISTOPHER OSCANYON, Turkish Consul-General at Washington, was refused by the Supreme Court the privilege of collecting a commission on arms purchased by him for Turkey, on the ground that a public officer has no right to sell his influence.

A DISPATCH from Wheatland says: After great perseverance the San Francisco Copper Co., at Spenceville, have been rewarded by striking a body of ore which shows by actual smelting fully 40% of copper.

THE Green Mountain Gold Mining Co., of Plumas county, paid a dividend of 7½ cents per share, in New York recently. This is the 22d dividend, and the grand total is \$146,750.

THE Starr-Grove Mining Co., of Nevada, has declared a dividend of 10 cents per share, payable at New York on the 30th of April. This will be the sixth dividend, making a total of \$120,000.

A rich strike has been made in the old McKee mine located in the White mountains, and about seven miles from Benton, the property of Caffery & Anderson.

THE Bodie *Free Press* says a number of miners have returned to that camp from Tombstone.

About 70 men are now employed at the Rising Sun mine, Colfax.

## Traveling Agents.

We want several canvassing agents who will make it their business to solicit subscriptions and advertising for our first-class progressive newspapers. Men of ability and experience can secure good pay and permanent employment. Send references and state your past occupation, etc., to the publishers of this paper.

## Our Agents,

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. F. OSBORN—San Francisco.  
A. C. KNOX—Sonoma, Napa, Lake and Mendocino counties.  
G. W. MCGRAW—Santa Clara county.  
M. P. OWEN—Santa Cruz county.  
J. W. A. WRIGHT—Merced, Tulare and Kern counties.  
N. E. BOYD—San Bernardino Co.  
JARRIS C. HOAG—California.  
B. W. CROWELL—Tehama and Butte counties.  
D. W. KILLGORE—Santa Barbara, Ventura and San Luis Obispo counties.  
A. LEONARD MEYER—Utah, Idaho and Montana Ter.

## Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct (or if the paper should ever come beyond the time desired), be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omission of agents.

PERSONS receiving a sample copy of the MINING AND SCIENTIFIC PRESS with this notice marked, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We will send it, on trial, at the rate of \$4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

IMPORTANT additions are being continually made to Woodward's Gardens. The grotto with its aquaria constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

A gentleman just arrived from Colorado who is thoroughly posted in the treatment of refractory ores, and who has been a director for 3 years in the Austrian Government Reduction Works in Europe, would like to engage his services to a Mining and Reduction Company, either as Superintendent or Assistant, or to take charge of the Assay Department. Address H. S., this office.

How to STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

The State Mining Bureau, No. 313 Pine street, is open to the public from 10 o'clock A. M. to 5 o'clock P. M., daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Lewis Consolidated Silver Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Pioneer Mining District, Pinal County, Arizona.

Notice is hereby given, that at a meeting of the Board of Directors, held on the Twenty-third (23) day of March, 1881, an assessment, No. Four (4) of Six (6) Cents per share was levied upon the capital stock of the Corporation, payable immediately, in U. S. Gold Coin, to the Secretary, at the office of the Company, No. 310 Pine Street, Room 15, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the Second (2) day of May, 1881, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the Twenty-third day of May, 1881, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

J. W. FEW, Sec'y.

Office, No. 310 Pine Street, Room 15, San Francisco, Cal.

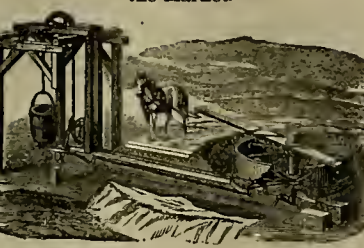

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

INCERSOLL  
ECLIPSE ROCK DRILLS.

The Most Economical Air Compressors in the Market.

MINERS' HORSE-POWER.

One Horse can easily belt over 1,000 pounds at a depth of 500 feet. The Power is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX,  
49 Fremont St., S. F.

Scientific and Practical Books  
on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,  
MINING ENGINEER AND METALLURGIST.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurates, and Gold and Silver Ores generally, with 120 Lithographic Diagrams, 1887.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver, 1880.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 155 pages, embracing illustrations of furnaces, upsmets and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, \$3.00 coin, postage free.

BUY LAND

Where you can get a crop every year; where you will make something every season; where you are sure of having a crop when prices are high; where you have a healthy place to live; where you can raise semi-tropical as well as other fruits; where you can raise a diversity of grain and vegetables and get a good price for them. Go and see the old Reading Grant (in the upper Sacramento Valley), and you will find such land for sale in sub-divisions to suit purchasers—at reasonable rates and on easy terms. Send stamp for map and circular to EDWARD FRISBIE, proprietor, (on the Grant), Anderson, Shasta Co., Cal.

BOILER COVERING

Wire-Bound Asbestos Boiler Covering and Agent for Reed's Boiler and Pipe Covering.

BRANCH OFFICE: 22 1/2 California Street.

OFFICE AND FACTORY: 314 Townsend St.

Cups for Engine, Machine and Shaft Bearings and Loose Pulleys. We furnish the Albany Compound (a solid), \$1 worth of which will last as long as from \$2 to \$10 worth of Oil, with no stop, and with ONE-TWENTIETH the ATTENTION required by the best Oil Cups.

If the Cups are not satisfactory, we will receive them back and make no charge.

Cylinder corrosion is not so much owing to impure tallow or oil as to the fact that these animal fats do not maintain their integrity under steam heat, but decompose and set free acids which attack and destroy metal.

The Albany Cylinder Oil does not contain fatty acids—is incapable of being decomposed and does not form insoluble soaps.

If it becomes mixed with boiler incrustation it diminishes its tendency to cling to the sides of the boiler, and thus exerts in this respect also a beneficial action.

THE ALBANY  
Cylinder Oil

Is now in use throughout the world, and we refer to nearly all first-class establishments on this coast for evidence of its efficacy.

The Cheapest and most economical Cylinder Cup. Can be instantly regulated to feed a few drops per minute, and the drops can be counted as they pass through the glass gauge.

Pure Winter Strained Lard Oil

By every vessel from New York.

ALBANY SPINDLE OIL,

Genuine West Virginia Lubricating Oil,

SIGNAL OIL for outside lights of vessels, etc.

The Albany Lubricating Compound and Cups, the Albany Spindle Oil, etc., can only be gotten from us or our agents. Send for catalogues.

Entirely different from other Saws. When dull, sharp teeth, which only cost a trifle, can be inserted in a few minutes, without taking the saw off of the mandrel, and no skill is required in doing it. Send for Catalogue showing their vast superiority. More of them are being sold than of any other kind, and we are altering all other kinds to the Chisel Tooth.

EXCELSIOR  
BLASTING POWDER

MANUFACTURED BY THE  
Excelsior Powder Company.

This is no so-called "safety" Powder, but a powerful explosive, and as safe to handle and use as any nitro-glycerine Powder on the continent. There is no headache or nausea in the use of this Powder, as the noxious fumes are entirely done away with. It is put up in cartridges of any size to suit consumers and is exploded with cap and fuse, the same as any other high explosive. The following testimonial is a sample of hundreds of the same tenor being constantly received:

GOLD HILL, August 17, 1880.

AGENT EXCELSIOR POWDER CO.—Dear Sir:—I have used your Powder in test cement and hard blasting rock, and find it superior to any Powder in use on the Coast. It does its work effectively, and does not leave the person using it with a severe headache, like the other Powders so to the majority of miners. In recommending it I would suggest, give it a fair trial and I am confident it will speak for itself. Wishing your Company success,  
I am respectfully yours, etc.,

GEORGE CLARK,  
Foreman Sierra G. and S. M. Co.

### California Brass Foundry,

No. 125 First Street, Opposite Minna.

SAN FRANCISCO, CAL.

All kinds of Brass, Composition, Zinc and Babbitt  
Metal Castings, Brass Ship Work of all kinds, Spikes,  
sheathing Nails, Rudder Braces, Hinges, Ship and Steam-  
boat Belts and Gongs of superior tone. All kinds of Cocks  
and Valves, Hydraulic Pipes and Nozzles, and Hose Cou-  
plings and Connections of all sizes and patterns, furnished  
with dispatch.  
J. H. WEED. PRICES MODERATE. V. KINGWELL.

### California Machine Works,

WM. H. BIRCH, Prop'r.

119 Beale Street, San Francisco.

General Mechanical Engineer and Machinist.  
Steam Engines, Flour, Quartz and Mining Machinery.  
Sole manufacturer of Brodie's Patent Rock Crushers and  
Steel-Faced Tappits. Agent and Manufacturer of F. A.  
Youse's Patent Steam Packing Rings for Steam Pistons.  
The best ever invented; can be applied to any Engine  
Piston and give entire satisfaction to those using. Steam,  
Hydraulic and Sidewalk Elevators. Repairing promptly at-  
tended to.

### STEAM ENGINES AND BOILERS

Of all sizes—from 2 to 80-Horse power. Also, Quartz  
Mills, Mining Pumps, Hoisting Machinery, Shafting, Iron  
works, etc. For sale at the lowest prices by

J. HENDY, 49 and 51 Fremont Street, S. F.

THOMAS THOMPSON. THORNTON THOMPSON.

THOMPSON BROTHERS,  
EUREKA FOUNDRY,

129 and 131 Beale St., between Mission and Howard, S. F.

MANUFACTURERS OF CASTINGS OF EVERY DESCRIPTION.

## CALIFORNIA Electric Light Company.

Owners of the Brush System of Electric Lighting for  
the Pacific Coast.

Apparatus for sale for Mines, Mills, Manufactories, etc.  
Plating Machines and Machines for treating Ore man-  
ufactured to order.

Electric Light furnished on all the principal streets  
the city.

Office—No. 119 O'Farrell Street,  
SAN FRANCISCO, CAL.

DODGE'S

UNEQUALLED

Concentrating Machinery

FOR CONCENTRATING GOLD, SILVER,  
LEAD and COPPER ORES.

Furnaces for Roasting and Chloridizing Ores, for Amal-  
gamation or Leaching.  
Plans, Drawings and Estimates for Working Ores by  
any Process.

PRESCOTT, SCOTT & CO.

## Pacific Iron Works.

Established in 1850.

RANKIN, BRAYTON & CO.

Office—127 First Street, San Francisco, Cal.

Builders of Engines, Boilers, all Classes of Machinery.

PLANTS FOR GOLD AND SILVER MILLS,

Embracing the latest and most Improved Machinery and Processes for Base and Free Ores.

WATER JACKET SMELTING FURNACES,

For both Galena and Copper Ores of the Most Improved Construction.

Having Built nearly every successful working Furnace on the Coast, we are prepared to guarantee the best results  
attainable in all classes of Ores.

HOISTING AND PUMPING MACHINERY,

Embracing all Known Improvements.

WHEELLOCK'S AUTOMATIC CUT-OFF ENGINE,

Beyond Question the most economical and perfect working Engine now made.

WALKER'S COMPOUND STEAM PUMPS,

The best in use. Will work with thirty per cent. less steam than any other Pump in the market.

Sole Agent for HOWELL'S IMPROVED WHITE FURNACE.

The only successful Chloridizing Furnace made. Over fifty of them in use on this Coast.

Parties Wanting any kind of Mining Machinery are requested to send for Illustrated Circular.

## DEWEY & CO.'S

Scientific Press

Patent Agency.

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old  
experienced, first-class Agency. We have able and trustworthy associates and Agents in Wash-  
ington and the capital cities of the principal nations of the world. In connection with our edi-  
torial, scientific and Patent Law Library, and record of original cases in our office, we have  
other advantages far beyond those which can be offered home inventors by other Agencies. The  
information accumulated through long and careful practice before the Office, and the frequent  
examination of Patents already granted, for the purpose of determining the patentability of  
inventions brought before us, enables us often to give advice which will save inventors the  
expense of applying for Patents upon inventions which are not new. Circulars of advice sent  
free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

A. T. DEWEY.

W. B. EWER.

GEO. H. STROCK.

## William Hawkins,

(SUCCESSOR TO HAWKINS & CANTRELL).

MACHINE WORKS,

210 and 212 Beale Street, bet. Howard and Folsom Sts., - - San Francisco.

Manufacturers of

IMPROVED PORTABLE HOISTING ENGINES,

FOR MINING AND OTHER PURPOSES.

Also of the HAWKINS' PATENT ELEVATOR HOIST, for Hotels, Warshouses  
and Public Buildings.

Steam Engines and all Kinds of Mill and Mining Machinery.

L. C. MARSHUTZ.

T. G. CANTRELL.

## National Iron Works.

Northwest Cor. Main and Howard Sts., San Francisco.

MANUFACTURERS OF

IMPROVED PORTABLE HOISTING ENGINES.

Stationary and Compound Engines, Quartz Crushing and Amalgamating  
Machines, Flour, Sugar and Saw Mills.

SOLE MANUFACTURERS OF

Kendall's Patent Quartz Mill, National Ore Feeder & Concentrator.

CASTINGS AND FORGINGS OF EVERY DESCRIPTION.

# STEEL CASTINGS

FROM 1-4 TO 10,000 lbs. WEIGHT.

True to pattern, sound and solid, of unequalled strength, toughness and  
durability.  
An invaluable substitute for forgings or cast-iron requiring three-fold  
strength.  
Gearing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Loco-  
motives, etc.  
15,000 Crank Shafts and 10,000 Gear Wheels of this Steel now running  
prove its superiority over other Steel Castings.  
CRANK SHAFTS, SHOES, DIES and GEARING specialties.  
Circulars and Price Lists free. Address

CHESTER STEEL CASTING CO.,

Works, CHESTER, Pa. 407 Liberty St., PHILADELPHIA

Corner Beale and Howard Sts.,

SAN FRANCISCO, CAL.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with  
Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when ad-  
visable.

STEAM LAUNCHES, Barges and Steam Tugs con-  
structed with reference to the Trade in which they are  
to be employed. Speed, tonnage and draft of water  
guaranteed.

STEAM BOILERS. Particular attention given to  
the quality of the material and workmanship, and none  
but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING  
MACHINERY made after the most approved plans.

Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size  
made in suitable lengths for connecting together,  
sheets rolled, punched, and packed for shipment ready  
to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and  
Water Pipe made by this establishment, riveted by  
Hydraulic Riveting Machinery, that quality of work  
being far superior to hand work.

SHIP WORK. Ship and Steam Capstans, Steam  
Winches, Air and Circulating Pumps, made after the  
most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City  
Water Works purposes, built with the celebrated Davy  
Valve Motion, superior to any other Pump.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER,

Several first premiums received  
for Quartz Mill Screens, and Per-  
forated Sheet Metals of every  
description. I would call special  
attention to my SLOT CUT and  
SLOT PUNCHED SCREENS,  
which are attracting much at-  
tention and giving universal  
satisfaction. This is the only  
establishment on the coast de-  
voted exclusively to the manu-  
facture of Screens. Mill owners using Battery Screens exten-  
sively can contract for large supplies at favorable rates  
Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

## HENDERSON'S COMBINED CATALOGUE OF SEEDS AND PLANTS

Will be Mailed Free to all who apply by  
Letter.

Our Experimental Grounds in  
which we test our Vegetable and  
Flower Seeds are most complete;  
and our Greenhouses for Plants  
(covering 3 acres in glass), are  
the largest in America.

PETER HENDERSON & CO.

35 Cortlandt Street, New York.

Rheumatism,  
And all CHRONIC and NERVOUS DISEASES.

**AT HOME.**

A Treatise on Compound Oxygen, giving the history of this new discovery, and a large record of most remarkable cures, will be mailed free to all who ask for it. Also, "Health and Life," a quarterly journal, containing much interesting information. Write for it. Address the proprietors, DR. STARKEY & PALEN, 1109 and 1111 Girard street, Philadelphia, Pa., or H. E. MATHEWS, 606 Montgomery street, San Francisco, Cal., from whom can be procured both information and supplies.

**L. P. DEGEN.**

MANUFACTURER OF

Also Water-Proof Leather Belting.

NO. 13 FREMONT ST., near Market, SAN FRANCISCO

**AMERICAN EXCHANGE HOTEL.**

Sansome Street, (Opposite Wells, Fargo & Co's Express), San Francisco.

This Hotel, under the management of CHAS. MONTGOMERY, has been thoroughly renovated, and being in the very center of all the Banks, Insurance Offices and Commission Merchants, it offers special inducements to Merchants from the Interior and Farmers.

Board, with Room, \$1.25 a day \$1.50 per day. Special rates by the week or month.

FREE COACH TO AND FROM THE HOTEL.

**\$1,000 CHALLENGE!**

**THE FRUE ORE CONCENTRATOR.**

Over 250 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal. Saves from 50 to 100 per cent. more than any other Concentrator in use, and the concentrations are clean from the first working. The wear and tear are merely nominal; the water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines. We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of \$1,000 each, and we mean business.

ADAMS & CARTER, Agents, Room 7, No. 109 California Street, S. F.

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS.

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive

**Judson Powder**

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. Triple Force Caps and all Grades of Fuse.

**BANDMANN, NIELSEN & CO.,**  
SAN FRANCISCO, CAL.

**"FRUE" ORE CONCENTRATORS.**

I have on hand and for sale, at LOW PRICES, a number of the above Concentrators, of the latest pattern and in perfect order.

**JOSHUA HENDY,**

Manufacturer of Quartz and Saw Mill Machinery

AGENT FOR "BAKER'S" ROTARY PRESSURE BLOWERS,

Hot Polished Shafting from the Akron Iron Company, Ohio. Also, "P. Blaisdell & Co's" Machinists' Tools. A Large Stock of New and Second hand Machinery at Machine Works.

Nos. 49 and 51 Fremont Street, San Francisco.

**J. S. PHILLIPS, M. E., ETC.**

May still be consulted by old friends. Address No. 1 Wall Street, New York.

**WIND MILL.**

One of the best made in this State for sale cheap on easy terms. Address, W. T., care of Dewey & Co., S. F.

**HUNTINGTON'S**  
Oscillating Stamp Mill

It has no Stems, Cams, or Tappets, and Adjusts itself to the Wear of the Shoes and Dies.

For Simplicity, Economy, Durability and Effective Working, it exceeds anything ever presented to the public, and will do the work of five stamps with one-fourth the power.

## A Novel Planing Machine.

We illustrate this week a novel planing machine, made by the San Francisco Tool Co., a machine so thoroughly a departure from common practice that it seems somewhat "revolutionary." Novelty is, however, no object in the design of this or any other machine tool of the company. There is a purpose in the arrangement throughout, which we will proceed to explain:

To meet the requirements of a small shop or where repair work is done, there is generally a shaping machine and one or more planing machines of the ordinary kind, and even with these there are often pieces to be planed that cannot be operated upon because of shape or dimensions.

The machine here shown is to meet such cases. It will perform nearly all kinds of planing on large or small pieces, and does not cost more or occupy more room than an ordinary shaping machine of similar capacity. The drawing is in true elevation, and shows clearly the method of construction.

The tools traverse parallel with the main frame, and adjust transversely 20 inches, or will plane over 24 inches wide, if required. The length of the stroke on the machine shown is from two inches to four feet.

There are two tables on which work can be fastened independently, or by placing a filling-in piece between a continuous table four ft. long is formed. For large pieces the two tables can be readily removed, and as the tools "overhang," almost any kind of a piece can be placed beneath and planed off.

The tools are driven by a strong steel screw, on which there are three separate nuts, making an aggregate length of 12 inches. One of these nuts adjusts so as to prevent backlash; and all are made from solid brass—not filled with type metal, as is common with the old screw-planing machines. There are no gear-wheels employed. The driving pulleys are placed directly on the end of the screw, so that the machine is noiseless—a feature that can be claimed for no other now in use.

In large works, where a "set" of planing and shaping machines are employed, there is less advantage from one having such a wide range of adaptation, but for present circumstances on this coast, and especially for repair work at mines or in large factories, such a machine tool cannot fail to meet the expectations of the company who have so boldly left the beaten track in deference to local requirements.

The company have a four-ft. machine ready for their own use, and are able to supply them of that or greater length.

For the cattle-car prize at Chicago 480 models and 243 plans were presented, 51 models and 81 plans coming from Illinois. There were eight ladies among the competitors. There have been 116 patents issued on cattle care by our Patent office.

TELEPHONES are received with favor in China, because a system can be carried out, which is impossible with the telegraph, owing to the peculiarities of the language and the difficulty of devising signs.

A STEAMER aground has checked the traffic of the Suez canal this week.

## The State Engineer.

It will be recollected that the Senate struck out of the appropriation bill the sum of \$30,000 for the salary of the State Engineer, and for the completion of the irrigation works of the State Engineer's department or a preparation of final report, with maps and illustrations. One afternoon of last week was devoted by the Assembly to the question as to whether or no it would concur on the Senate amendment which cut out this sum. The debate was largely a repetition of the arguments pro and con advanced at the time the House had the subject under consideration before. The Sacramento Bee says:

"Wasson, of Mono, attracted much attention by making his maiden speech of the session on the subject. He has always been regarded as a silent, hard-working member, who interfered with no one else's business and always attended to his own, looking all the while to the advancement of the interests of his constituents. He spoke strongly in favor of making the appropriation and against the Senate amendment striking it out. Said he: All the southern counties have been mentioned by previous

cal survey as yet, and that it had been cut off just where it should have been continued.

Other speeches were made, and the House refused to strike out the appropriations by a vote of 39 yeas to 33 nays.

## Montana Placer Mines.

A correspondent of the Press writes from Virginia City, Montana, and says that their mining season opened three or four weeks earlier than usual this year. He commenced sluicing March 19th, and has had little trouble with frost. November, December and January were cold and stormy, and large quantities of snow drifted and stored away in the mountains, and placer miners anticipate a steady supply of water, and consequently a more than ordinarily prosperous season.

Alder gulch miners depend almost entirely on the natural flow for water. Some lakes near the head of the gulch, which have a natural outlet in another direction, have for a number of years been utilized as reservoirs, and during three of the driest months of the season furnish nearly as much water as the natural flow of Alder gulch. Several projects to bring on wa-

## Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening, Prof. Davidson in the chair. Charles F. Crocker and L. E. Blockman were elected members. Among the donations to the museum were the following:

Two ribbon seals, fully mounted, from Capt. Lewis W. Williams, of the brig *Hidalgo*. Also the collection outfit furnished by the Swedish government to Dr. Gustav Eisen, and used in marine dredging on this coast. This was purchased by the Alaska Commercial Company, and by them presented to the Academy.

Mr. Dwight Whiting presented the tooth of a fossil horse, found 200 ft. below the surface, where it was picked up on the hard pan, in the workings of the Spring Valley hydraulic mine, at Cherokee Flat, Butte county, Cal. It is an exceedingly interesting and quite valuable fossil specimen, and very like some found in the breccia beds below Los Angeles. Mr. R. H. Stretch presented a rodent, called by the Indians swellel, a very rare animal, which cuts off plants and lays them up to dry like hay.

Four specimens of calcareous tufa from Soda springs, Mendocino county, Cal., by J. McNabb; specimens magnesite and specimen steatite, foothills back of Visalia, from C. Comcoe; two specimens gray antimony and specimen of lead ore from Mexico, by E. T. Cox; 4 specimens of gray antimony found 12 miles east of Hollister, San Benito county, by G. F. Beardsley. From J. C. Crocker, specimens of calcareous tufa, quartz, mica, schist, red jasper, chalcedonic quartz, gypsum, all from Coast range west of Buena Vista, Elough, Kern county. From A. O. Thoms, Bakersfield, specimens of

free-gold quartz and copper ores from Kern county, and silver and copper ore from Inyo county. From C. D. Gibbs, specimens of gypsum, water-worn stone, green marl, impure asphaltum, Kern county. From Foye Bros., specimen German black lead. From W. H. Wallace, garnets in matrix of micaceous schist, from Slicken river, Alaska. A specimen of stone adze from Arizona was presented. Mr. Redding thought it strange, that while these adzes were found in Alaska and in Arizona, none were found in this State. Prof. Davidson said he had seen them at Port Orford, Oregon.

W. G. W. Harford, Director of the Museum of the Academy, read a paper on "Seals," describing the different varieties, their peculiarities and habits.

Capt. A. E. Bruno delivered the second of his lectures, describing his adventures in the South Pacific islands, speaking, on this occasion, more particularly of the New Guinea. One of the natives of the New Hebrides islands, a boy about ten years of age, was with Capt. Bruno, and attracted much attention at the meeting.

THE Big Horn, Grey Bull, Yellowstone, Sun River, Wood River and Teton countries are described for the benefit of prospectors, in the book advertised in another column by J. A. Campbell & Co.

It is said that the Spanish free traders urge the Cabinet to negotiate a treaty of commerce with the United States in order to obtain special concessions for exports from Cuba.

COMPOUND PLANING AND SHAPING MACHINE.

speakers, except Inyo and Mono. It is for this reason, Mr. Speaker, that I desire the floor. I desire to state that the waters heading in Mono county and running through Inyo are greater than all which originate in San Bernardino, Los Angeles and San Diego. In that proportion the irrigable lands in Owen's valley are correspondingly great. I have favored the Drainage act throughout, and I have nothing in that connection to take back. Much has been said about the maps of the State Engineer—they were simply a necessary incident in connection with irrigation. It now resolves itself into the question—in connection with these maps—to furnish written reports describing the quality and quantity of land and the amount of water contiguous thereto. It is not a question of water already appropriated; it is a question of storing away of the water which runs off during the melting of snows and in the rainy seasons. The question of riparian rights and water already appropriated is a question of law—all the rest of the information which can possibly be gathered is of importance to the poor people who now live here, or who may desire to come. Owen's valley alone has land and contiguous water enough to support 100,000 people, but it is as unknown as if it was in the moon. If they say this information is not important on the part of the State to give to the world, then you might as well cut off the Census Bureau in the giving of its statistics on immigration and emigration, also the commissions which give information on the subject of horticulture, agriculture and mineralogy. He claimed that there was no geologi-

cal survey as yet, and that it had been cut off just where it should have been continued.

Other speeches were made, and the House refused to strike out the appropriations by a vote of 39 yeas to 33 nays.

Alder gulch is mostly held in large tracts by 11 different companies and individuals. These are, nearly without exception, composed of men who, with indomitable energy, have stood by Alder gulch through evil report and good report, and have finally been successful in securing a competence for old age.

It is fashionable just now in England to organize all the new companies, with £1 shares. Indian gold mining companies seem to have set the fashion. The English papers think the idea a good one, as it enables small capitalists to invest, and gets as many shareholders who will be likely to attend meetings of the companies.

With all the Indian gold mining companies organized of late in London, not one has yet paid any dividends.

The French have gained several victories over the insurgents in Tunis, and are continuing their forward march.

## CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eos

### Stirring Roasting Ore.

EDITORS PRESS:—I have just seen Mr. Knstet's communication on the above subject, in your issue of February 5th, referring to my remarks on "wheels instead of bars" in roasting furnaces. The subject is not an important one, as the various mechanical furnaces are rapidly superseding the reverberatory in this country, but the proposition advanced by me, namely that the single pivoted wheel, when attached to the front of the door-frame, reduces the angular range of the hoe, is a mathematical one, easily demonstrated by means of a simple diagram. To prove that I am not "ignoring facts," I will state a few.

The door frames with wheels, used by Mr. Knstet at Melrose, but rejected by Mr. Stewart, who built a new furnace, are now, or some of them, in a two-hearth furnace at the Chicago mine in Shasta county. This furnace was constructed under my direction, the lines for the walls being marked on the hearth to conform to the range of movement of the hoe, as directed in my book on "Leaching Gold and Silver Ores," the area of the hearth being several square ft. less than would have been the case had I used bars, or the common long rollers, instead of the wheels. I expected the wheels to work well, but the gentleman in charge of the mill does not like them, and intends to substitute bars. C. H. AARON.

### Climate of Tehama County.

Here as elsewhere, climate is affected by the following agents, viz.: latitude, proximity and access to the ocean and its currents, altitude above level of ocean, its position as regards mountain ranges, &c.

(1.) The latitude of the county, as well in fact of the whole State, tends to make the average climate a pleasing medium between the intense cold of the north and burning heat of the tropics. Our latitude is such that during the sun's greatest distance north, the currents of air caused at the solar vertical (by refraction) having turned to the north descend upon us as dry winds, we being within the second wind zone (from 32° to 43° north latitude) thus giving us a hot and dry summer. During the months of the sun's greatest distance south, the rain zone, on account of the position of the sun, is somewhat changed, thus bringing us within its range and giving us our wet season.

(2.) The elevation of Tehama county varies from about 300 ft. at the river to 5,000 or 6,000 ft. in the extreme west, and 8,000 or 10,000 in the east. The portion of the county included in the valley averages about 400 or 500 ft. above the level of the ocean. We therefore have a climate which is much affected by elevation. This, during the summer months, is taken advantage of by a goodly portion of the population, who, having prepared themselves with a camping outfit, leave behind them the oppressive heat and dust, the cares and perplexities of business, and, facing either eastward or westward, go up, up, up, through all the degree of temperature, from the most oppressive heat to a most enjoyable degree of coolness and healthfulness.

(3.) Some of the effects of the proximity to the mountains have been mentioned; one of the principal effects is caused upon the temperature of the nights, especially in the spring, by the melting of the snow.

(4.) We owe it principally to the warm currents of the Pacific ocean that our climate is such as places us below the snow limit, whereas a distance of 8,000 miles to the east must be traversed before we arrive at a point where this again occurs in the same latitude. True, the effect of these ocean currents, which strike this coast from Japan, is somewhat impaired by the Coast Range mountains, which form a great barrier; but this is compensated for by the fact that the two ranges of mountains (the Coast Range and the Sierra Nevada) close up the great caueway at the head of the valley, and inclose a body of air, which is in a measurable degree shut up by itself, and therefore tending to hold an even temperature.

MILL CREEK.—There is probably no camp on the coast, says the *Homer Mining Index*, that offers so many inducements to men of small means as Mill Creek. There is an abundance of water-power here during the greater portion of the year, and a great many small veins which will pay well in arastras. A few hundred dollars will build an arastra capable of reducing two and a half or three tons a day, and sometimes more. Along the west side of Lake canyon there is a large quantity of float quartz, some of it being very rich. In some places it is so plentiful that several hundred pounds may be gathered within an area of a few yards. There is enough of this float in sight to keep a number of large arastras going for a long time. The district is not half prospected, and there is every probability many good veins remain to be discovered.

## Copper Smelting—Its History and Processes.—No. 4.

[By HENRY HUBSEY VIVIAN, M. P.]

Now here we have it distinctly stated that Jochim Gans devised this manner of working after he was at Keswick, and it is plain that he did not bring the new "manner" with him. At the bottom of page 23 this passage occurs: "The number, nature and properties of which is full of humorous being wholly unknown to Mr. Daniell and his Sonne, or to any other of the Dutch workmen w<sup>ch</sup> have bin sent from Germany to the mines, that have bin in our copper ures, has bin the only cause of the unreasonable charge and long tyme spent before they could make of these ures perfect rough copper; which copper after the order used in tymes past by Mr. Daniell and his Son they never could, neither yet can make under xxii tymes passing thro the fire and xxii weekes doing thereof and sometyne more." "But now by Mr. Jochim's order of working we can—by once roasting and once smelting the ore (w<sup>ch</sup> shall be done in the space of three days), the same copper ore shall yield us black copper and copper stone, which neither Mr. Daniell nor his Sonne could or yet can do under xvi tymes passing through the fire and xvi weekes in doing thereof, and further in once roasting and once smelting the same black copper and copper stone again, which shall be done in two days after Mr. Jochim's order of working, I will bringe the black copper and copper stone into perfect rough copper, which Mr. Stemberger cannot make under xxii tymes passing through the fire and xxii weekes in doing thereof and sometyne more." Again at page 25, paragraph 4, we have the following, which distinctly proves reverberatory calcining, "hut hy stampinge the copper ore into powder and by roastinge the same powder after Mr. Jochim's order before it he smolten, and then letting water passe through the same roasted powder, the water doth not only carry the vitrial from the powder or ore, but also carries with it the burnt sinder of the sulphur." Now these extracts show the nature of the improvements introduced by Jochim Gans, and I know of no other way in which such effects could have been produced except by the reverberatory calciner and furnace. It must be observed that Nedham reports that by once roasting and once melting, black copper and copper stone (regulus) were produced in three days. Such a thing I believe to be only possible by using reverberatory calciners. Again he states that in once roasting and once melting, this black copper and regulus can be made into perfect rough copper in two days; this could only be done by the reverberatory furnace. Both these passages prove to me conclusively that the "manner" or "order" of working devised by Jochim Gans at Keswick was the reverberatory furnace process. He was doubtless a German, but he did not bring the process from Germany. I am not aware that there is any positive proof of the first use of the reverberatory furnace for copper smelting; but the extracts I have read contain such strong inferential proof that, until I hear something of a more certain character to the contrary, I shall give Jochim Gans the credit of having devised that most important "manner" of copper smelting at Keswick in Cumberland, in 1581-82, just 300 years ago. Jochim Gans at the same time proposed to wash out sulphate of copper from calcined ore, and Nedham, in his report to Lord Walsingham, devotes much space to this plausible proposal. The same idea has occurred to many a man since his time, and in each case

In Practice It Has Proved as Unprofitable As no doubt it did 300 years ago; for we hear no more of poor Jochim Gans or his sulphate process.

The next notice we have which I think it worth while touching upon is contained in a correspondence between Ulrich Frosse and His Right Worshipful Thomas Smith, Esq., Principal Customer of London, at his house in Fenchurch St., in London, 7th July, 1584, therefore two or three years later than the extract just given. Customer Smith was a holder of one-quarter part of a share of 1-14th in the "Mines Royal Society" in 1580-1-15th part. Ulrich Frosse is mentioned by a Mr. Carnsew as superintending a mine in Cornwall, and I infer that "he was a Cumberland man, because Mr. Carnsew proposes that he should take such men as he is now acquainted with of our countrymen, and work in competition with certain German miners whom Mr. Weston had introduced at Trewoorth, near Perin Sandes," Cornwall." On the 21st July, 1584, Thomas Smith writes to Ulrich Frosse, saying that Mr. Weston is going to Cornwall through Wales, and that he will take measures for transporting the copper ores to the "new melting-house at Neath, in Wales, which house, I understand, is ready, and we have taken order here that against he shall be ready to make copper he shall have from Keswick one of our copper makers, with an under melter and the Dutch carpenter, for a time, to serve and ready him in these causes." Now this fixes the exact date of the commencement of copper smelting in South Wales, namely, the autumn of 1584, and it shows that the skilled workmen came from Keswick. As the carpenter is especially called a Dutchman, I think it follows that the "copper maker" and "under melter" were not Germans. It is possible that the Dutch carpenter was a skilled millwright, as, later on, water power is mentioned, probably in connection either with blast or stamping machinery. In the latter part of the same letter, Ulrich

Frosse is told that "about Michaelmas next he shall go bye at Neath to take charge of our melting-houss and things there." Frosse writes to Carnsew on the 3d August, 1584, from Outbert parish, in Cornwall, a letter which seems to indicate that they had been trying to smelt in Cornwall, and had got the regulus and slag mixed up together. On the 9th June, 1585, Frosse writes from Neath to Mr. Carnsew. He advises having sent samples of their stones, or regulus, and copper, and complained he was waiting for more and richer ores from Cornwall, and wanted "to repair his water-wesre and furnaces." On the 4th July, 1585, Frosse writes to Dsham that they "had founde out a ways to mste 24 C of owre everye daye with one furnace, the Lord be thanked, and if we may have owre enough from yor side, we maye, with God's helpe, mste with tow furnaces in 40 weeks 560 tonnes of owre, having reasonable provision made for it; desiring yow from hence forward to sende such owres as yow have with as much speed as may be, not caring what owre it is." It appears, therefore, that, within less than a year after the works were started, Frosse felt master of the position, and was able to deal with whatever ore they sent him, but they had not yet refined copper. On the 7th March, 1586, Ulrich Frosse wrote to Mr. Carnsew: "Wee looke dayley for the copper refiner from Keswick, and have in readines as much copper roste and blake copper as will make a 20 tonne of good copper." He reported in the same letter that he "could melt in 7 hours 24c. of owre, with 8 or 9 seks of chare coles and 3 horslod of sea coles; melting many eorts of owres to gither ie the most profet and will emelt a greattall sonner." Now this passage shows that they had so increased their melting as to do upward of three tone per 24 hours, and that they could take any kind of ore, but, above all, it proves that they were

### Using Reverberatory Furnaces.

Because "sea coles" are suitable for such furnaces and not for blast furnaces. The charcoal was probably mixed with the coal to prevent its hindering too strongly, just as we now use "free" coal. The charge of 24 cwt. was curiously enough the same which was used by works up to a recent date. My object in giving these extracts is to show, not alone how copper smelting commenced in South Wales, which is of great local interest, but also how the South Welsh process of copper smelting, which may be said to be at this moment the ruling process of the world, began. The first introduction of copper smelting in Lancashire seems to have been in 1717, near Warrington. I think these extracts clearly prove that in 1581 Jochim Gans "devised a manner" of working copper ores at Keswick, which enabled him, by once roasting and once melting the ore, to produce black copper in three days from powdered ore, and I know of no other system than reverberatory furnaces by which that result could be attained; and we find Ulrich Frosse four years later, at Neath, with all the experience of Keswick, advising his employers that he had found out a way to melt a considerable quantity of ore per day in one furnace, "the Lord be thanked," and that he could deal with all kinds of ores, using sea-coal as fuel, which shows, beyond doubt, that he had improved Jochim Gans's reverberatories and was using them. This, I think, is the history of the invention by one man, and practical working out by another, of the South Welsh system of smelting copper. And now I naturally come to the consideration of that system, both in comparison with the European and Asiatic systems, and on its own merits.

### When I use the term

South Welsh System of Copper Smelting, I carefully avoid the term "principle" of copper smelting, because the same "principle" must be the base of all copper smelting. The ends are the same, but the means of attaining them are different. The difference lies in our use of reverberatory furnaces both for calcining and melting, while the other systems of the world depend (or perhaps more correctly depended) on roasting in heaps and melting in blast furnaces.

Let us then first consider the processes which must be gone through in either case to produce copper from its ores. Now, what are its ores? If you turn to a work on mineralogy or chemistry, you will find an infinite variety of ores and combinations of copper, 25 at least; but in practice copper occurs in nine cases out of ten in combination with sulphur. In by-gone times, large quantities of carbonates came to us from Anstralia and Chili. Even now, the latter sends us occasional cargoes of green ores, containing carbonates, silicates, chlorides, oxides, and other combinations of copper; but these ores unfortunately bear but a small proportion to the ore containing copper in combination with sulphur. The same is the case in other parts of the world, and we may therefore direct our attention almost exclusively to the smelting of sulphide of copper in combination with sulphide of iron, earthy matters, and every known and unknown metal and mineral in creation.

(TO BE CONTINUED.)

LUBRICATING GEARS.—Where a mill is driven by a mortise gearing, it has been recommended to use a mixture of pulverized chalk and linseed oil for lubricating purposes. It is said that this mixture is much better for wooden cogs than oil, tallow or flour. The chalk for this mixture should first be pulverized and then sifted with a fine sieve.

THE Brunswick and Woodworth mills, Carson river, will shortly be started up on tailings.

## Safety for Miners.

The burning of hoisting works over the shafts of mines is not of uncommon occurrences, and when such accidents occur they invariably prove fatal to all the miners underground at the time, if there be no other escape for the men than through the shaft over which the building is burning. The suffocation of four men in the Goodshaw by this means a few months since is still fresh in the minds of many. In that case the fire was attributed to the negligence of the engineer. But however careful an engineer or vigilant a watchman, and even with the best possible appliances for the extinguishment of fire, such an accident is liable to occur at any hour—by the explosion of a hoiler, etc. There are a number of mines in Bodie from the interior of which there is

### No Escape

Whatever, save through a single shaft covered by a building that is liable to burn down at any hour. The fire need not extend 10 ft. down the shaft to prove fatal to the imprisoned miners; the heat of the fire at the surface very soon exhausts the oxygen of the atmosphere in the mine, and the men are asphyxiated. Fatal results might be avoided in 99 out of every 100 such accidents by the following cheap and simple device, which the *Free Press* suggests for the consideration of mine superintendents and others having in charge the working of mines that have no connection with other mines through which miners might escape to the surface in case of the burning of a shaft house: Place strong and heavy iron drop doors in each compartment of the shaft, some distance beneath the surface, and let them be held up and open by a common hempen rope extending to the surface and so arranged about the top of the shaft that they will be burned in two at the first

### Approach of Fire,

Thus allowing the doors to close. To prevent them being raised by the tremendous draft caused by the heat above, they should be held down by a spring bolt. These doors would prevent the exhaustion of oxygen of the atmosphere of the lower levels for a long time; but by running a drift from the shaft to the surface, just below the iron doors, the atmosphere of the lower levels could never be materially altered by the heat above. This drift could be made to reach the surface at very little cost and at a safe distance from the burning building, and the men from below could ascend the ladders under the shield of the doors and escape through the drift or tunnel suggested. The doors might be placed within 20 ft. of the surface—thus lessening the danger of being broken by fallen timbers by lessening the fall of the timbers—and the drift run out under the waste dump. The whole arrangement would not cost more than \$250, and the suggestion is worthy the attention of mining men.—*Bodie Free Press*.

## A New Gravel Mining Enterprise.

De Groot, Birge & Co., of San Francisco, are opening up for the Massachusetts Mining & Investment Co., which recently formed at Boston for that purpose an incorporation called the Willow Creek Mining Co., a gravel claim on Willow creek, near the North Yuba, between Camptonville and Bullard's Bar, in Yuba county. The claim embraces what is known as Garden valley, which is one-fourth of a mile wide and one and a half mile long. Early in the fifties considerable placer mining was done there with very favorable results, the deposits of gravel being found quite rich in places. About 1853 or 1854, before the gold had been near all extracted, the big mines at Camptonville, Weed's Point, Railroad Hill and other places above there began to run their tailings into the valley, and as there was but little fall to the bedrock drove out the miners, and covered up the shallow but productive placer deposits which in the upper part of the valley are said to have been intact at the time. The bed of siltens is now from 12 to 20 ft. in depth. The Bostonians propose to work all of this ground to bedrock. H. De Groot has been there for six weeks past preparing to begin operations, and is about to let a contract for the construction of 475 rods of ditch, 250 rods of flume and 6,000 ft. of iron pipe, with a carrying capacity of 1,500 inches, through which to convey water to the ground. About 100 men will necessarily be employed by the successful bidders in doing the work. As there is no dump to permit of this vast mass of tailings and gravel being washed down and out of the lower end of the valley, it must be raised up out of the sink and carried away through flumes, 30 or 40 ft. above. For this purpose an improved elevator will be used. It consists of pipe inclined at an angle of 35°, the lower end resting in the claim. Into this a stream of water having a pressure of 400 ft. will be turned, and a little giant will be used to drive the tailings in front of the bottom orifice, where the stream will force it up through the pipe and into the sluices. After the work is once fairly inaugurated, six or eight men will be sufficient to do all the work around the claim. The projectors estimate that all of the dirt, including the wash from the mines above, will pay for working.—*Nevada Transcript*.

THE net profits of the Dunkin mine at Leadville for March are stated by Supt. Ford to be \$25,000.

## MECHANICAL PROGRESS.

## A New Silver Steel.

In seeking for an inoxidizable alloy, Mr. Peter de Villiers, M. D., of Silver Hill, St. Leonard's-on-the-Sea, England, has discovered that certain metals will not unite in certain proportions, and he has utilized this discovery to coat steel so perfectly that even the cutting edge of a knife blade is not blunted, or, rather, that the silvery surface remains uninjured when the knife is sharpened. In the first place, he makes an alloy of tin, 80; lead, 18; silver, 2=100 parts; or of tin, 90; lead, 9; silver, 1=100 parts. The tin is first melted, and when a brilliant whiteness of the surface of the metal indicates its thorough fusion the lead is added in a granular state, and the mixture is gradually stirred, preferably with a rod of very dry fir-wood. The silver, separately melted, is then added to and mixed in like manner with the compound. At this moment the fire under the melting pot or crucible containing the alloy must be quickly increased, till the surface of the metal has a slightly yellow tinge. It is then rapidly stirred, and run into molds to form ingots. When he has the choice between iron and steel for the manufacture of any article to be coated he takes the purest steel used for manufacturing purposes. The blade of a knife, for example, is immersed in a bath of a solution of muriatic or sulphuric acid—1 to 10 parts acid to 100 parts distilled water or filtered rain water, or weak aquafortis. When the blade is withdrawn from the bath it must immediately be plunged into pure water to be quickly and completely washed, and then it is wiped and dried as rapidly as possible with a piece of old linen, soft leather, or a very dry sponge. It is then subjected for about five minutes to a dry heat in a furnace or oven heated to 70° or 80° C.; it is then withdrawn and again wiped. The preceding operations have for their object the preparation of the iron or steel for impregnation with the alloy, the result being that the said iron or steel is perforated with a multitude of holes almost infinitesimally small. In iron, unless this metal is of excellent quality, the size of these holes is extremely variable, and sometimes there are defective parts which make the subsequent operations very difficult. In steel the difference of diameter of these holes is almost imperceptible, so that the subsequent operations are performed without difficulty. This is the chief reason of his preference for steel.

The knife-blade or other article, after its preparation as above described, is immersed in a metallic bath composed of the alloy made according to one or the other of the formulas hereinbefore given. The ingots are melted in a crucible of plumbago or refractory clay, and not in an iron vessel, as particles of the iron would mix with the alloy and render the same liable to oxidize in the open air, thus impairing the appearance of the impregnated knife-blade or other article. The iron or steel, previous to immersion in the metallic bath or alloy must be heated to a temperature of 50° or 60° Centigrade; the bath must be perfectly liquid, and stirred with a dry rod of fir-wood or poplar, and the surface of the molten alloy must present a fine, silver-white color, which is obtained by slow fusion and by stirring only when the whole of the mass is liquefied. If these precautions are observed the impregnation of the iron or steel will proceed rapidly, and the alloy will enter the artificially produced holes and the pores of the metal, which are slightly dilated by the previous heating of the said metal. For a knife-blade or similarly thin object an immersion in the alloy of a few seconds will suffice. A period of from two to five minutes will be required for pieces or articles of greater thickness, such as horse's bits, stable chains and the like.

When withdrawn from the metallic bath, the blade or other article of iron or steel is at once immersed in cold water, or is otherwise properly treated to harden or temper it, or to restore its temper as required. If left in the cold water for too long a time, the metal sometimes becomes brittle, and carelessness on the part of the operator will prevent any difficulty of this kind. The blade or other article having been wiped and dried without the application of heat, is polished in any suitable manner. It will then have the whiteness and luster of silver, and will have a ring or sound analogous to that of the latter metal, and may be considered unoxidizable under ordinary atmospheric conditions. But to obtain a more complete result, he gives it a second bath in an amalgam composed of mercury, 60; tin, 39; silver 1=100 parts. It is then either placed in hot molten silver, or has silver deposited thereon cold by means of electro-deposition, so as to obtain a new covering or coating to form part of the impregnating metal, as the latter forms part of the steel or iron.

The final operation consists in polishing the articles by rotating apparatus, suitable to the form of the blade or other articles treated, but the objects which are impregnated by means of the hot bath of molten silver are tempered again when taken out of said bath, and before they are definitely polished. The articles so prepared, whether originally made of steel, iron, bronze, German silver, or any other metal or composition capable of bearing the heat to which they will have to be exposed, according

to his invention became remarkably hard and sonorous, these qualities resulting from the impregnation above described. He has described the process with respect to knife blades as an example, but desires it to be understood that other articles or objects of many kinds may be treated thereby with great advantage; for instance the process may be applied with great advantage to many utensils in which inoxidizability is a valuable quality, and may also be applied for many industrial or manufacturing purposes. The process is not costly, and the difference in the price of articles so made, and that of well finished goods manufactured in the ordinary manner, is amply compensated for by the saving in time and wear in cleaning. Thus, a knife-blade made as above described only requires to be cleaned by means of soft linen or wash-leather to preserve its appearance and silver polish. It can, moreover, be sharpened, and will keep its edge for as long a time as a steel knife would do.

**MORE DAYLIGHT.**—The London *Building and Engineering Times* describes a system designed to give light in passages and portions of offices, stores and other parts of buildings where, from close packing and a want of space, sunshine scarcely penetrates. It consists in inserting semi-prismatic lens-lights in such positions as will allow refracted daylight to be admitted, even on a dull and cloudy day. These semi-prismatic lights are made in a variety of forms; they consist of cast-iron frames into which are glazed either rectangular or hexagonal semi-prismatic reflecting lenses made from clear crystal glass, so placed that the light is reflected through the lens at such an angle as to slope from the front to the back of wherever they are *in situ*. At the distance of 60 ft. from the front of the premises, we were able to read the smallest print, and the only source of light in a cellar used as a storeroom was that which passed through one of the pavement lights under notice. The same principle has been applied in an improved safety coal plate, in flagged or asphalt pavements, and these are being extensively used in the streets of the metropolis; also in the form of sloping boards instead of window sashes, and giving as much protection as unsightly iron railings, besides affording ventilation, while they reflect additional light into basements outside of which they are fixed.

**RAILROAD SYSTEM OF MEXICO.**—The St. Louis *Republican* publishes, on what it claims to be good authority, some important facts in regard to railroad construction in Mexico. It appears that the Mexican government has granted very liberal subsidies to a narrow-gauge railroad to be built, which will be a continuation of the Denver and Rio Grande road, to the city of Mexico, and from thence westward to the Pacific ocean, at or near Manzanillo. The work is to be commenced immediately at the city of Mexico, and to be pushed with all reasonable dispatch both north and west. The road, when completed, will be about 2,000 miles long, and will be known as the Mexican Central. The *Republican* also has information from a high official of the Denver and Rio Grande company that that road will be completed to Laredo within two years. The line is now finished to Santa Cruz, N. M., and being vigorously pushed southward. An incomplete road from Corpus Christi, Texas, at the mouth of the Rio Grande to Laredo has been purchased by the Denver and Rio Grande company, and a 40-mile gap in it will be finished as speedily as the grading and track laying can be accomplished. When this work is done it will afford connection between Laredo and Galveston, New Orleans, other Gulf ports, and be a great aid in the transportation of supplies of iron, etc., to the contractors on the Mexican line proper.

**INFLUENCE OF HARDNESS ON MAGNETIZED STEEL.**—It has been proved by Herren Strouhal and Barns, from experiments in which steel wire was treated so as to show all degrees of hardness between the glass-hard and annealed states, that the thermo-electric and galvanic properties of steel vary with the degree of hardness in a very sensitive manner. Their researches, which were published in Wiedemann's *Annalen*, throw some useful light on the nature of the annealing process, and on the magnetic behavior of steel in relation to its hardness and other properties, a subject which fully deserves the closest investigation.

**A CABLE-LAYING SHIP** possibly represents the highest development of marine engineering, for a hitch in the machinery may mean the failure of the expedition. An instance of the perfection which has been reached has been furnished by the cable-ship, *Kangaroo*, which ran recently from New Zealand to St. Vincent without once stopping the engines. The distance of 9,500 miles, supposing about 16 miles to be run every hour, represents continuous work for 25 days—a fairly sufficient testimonial to the excellence of the machinery.

**NEW USE FOR COPPER.**—It is proposed to make use of large quantities of copper in the production of phosphor-bronze, from which telegraph wires may be made. Prof. E. Bede, formerly of the Liege University, highly recommends phosphor-bronze for wires, it having four times the ductility of iron and being from three to four times as strong as steel. Aerial lines are easily inspected, but are liable to accident, while underground lines, while almost exempt from accident, are difficult of inspection.

## SCIENTIFIC PROGRESS.

## The Future Life.

Years ago, in the days of Bishop Butler, very much stress was laid upon the analogies in nature, illustrating and supporting the idea of a future life, and the treatises then written were models of intellectual power and patient research. A great impression was produced, not only upon uneducated, but educated minds. Since that period science has progressed with giant strides, and at every step has so largely added to the list of striking analogies or incidental proofs, that the illustrations of early date seem few in number and dwarfed in proportion and force. The idea of an unseen immaterial existence involves also the idea of unseen activities and correspondences in the rayless realm. The most stolid of such cannot fail to be impressed with the beautiful analogies which recent scientific discovery affords.

Do we not every day converse with unseen friends a long distance away? Do we not recognize their familiar voices in homes separated from us by rivers, woods and mountains? These voices come out of the darkness, guided by a frail wire which science provides as a pathway. Even the curtain of night is drawn about us, the voices are heard, and we have not the shadow of a doubt of their integrity and identity. And further, have we not analogies of sight which startle us by their significance? Is it not true that when abroad we are open to the view of unseen observers long distances from us, and our every act and movement known? The excellence of optical instruments is such that we have seen the motion of lips of persons in conversation while sitting on a house balcony three miles distant, the observed, of course, wholly unconscious of being seen by anyone.

If our friends in this life, dead to us (hidden as they are by the shroud of space), can be seen, and we can hear their voices, their shouts of laughter, the words of the hymns they sing, the cries of the little ones in the mother's arms, is it very absurd to anticipate a time when those dead to us by the dissolution of the body may, by some unknown telephony, send to us voices from a realm close at hand, but hidden from mortal vision? We have no proofs to offer that this realm of the departed of this home of the soul is close at hand, but it is certainly more reasonable to adopt this hypothesis than the popular one of a material world or place somewhere afar off in the depths of space. One view seems possible, the other absurd.—*Boston Journal of Chemistry.*

**A NEW METHOD.**—In a recent report to the British Parliament, Dr. Angus Smith claims to have discovered a new method of examining the atmospheric conditions of manufacturing towns. He expects to be able to show how much a town or country suffers loss of light, and to find "how much this loss affects the health of plants, and it may be of animals and of man." The test is a chemical one, and rests upon the fact that when iodide of potassium in solution is treated with a small quantity of nitric acid a change takes place when the mixture is brought to the light, and the amount of iodine that is set free can be measured with great exactness. This is the germ of a process for measuring light, which the scientists will call a photometric process, that may be developed in time into a valuable agent for the examination of climate. There can be, Dr. Smith suggests, no real progress in sanitary economy without the full knowledge to be obtained by the examination of the air. He has found ammonia upon every object he has examined, indoors and out of doors, in the towns and in the country. Ammonia, it is believed, may be an index of decayed matter. By suspending a piece of glass anywhere, and after a while washing the outer surface with pure water by means of a spray bottle, and applying a Nessler solution to the washing, the presence and quantity of ammonia are ascertained. This Dr. Smith hopes to make "a ready popular test for air, a test for sewer-gas, for overcrowding, for cleanliness of habitations, and even of furniture, as well as for smoke and all the sources of ammonia."

**NEW CONCLUSIONS.—THE PHOTOPHONE.**—The opinion is gaining ground, especially among French savants, that the musical sounds produced by Prof. Bell in disks of various substances, such as mica, India rubber, metal and wood, by holding them in the path of a rapidly interrupted beam of light, are really due to heat and not to light. Radiophonic notes, such is the new term, have been obtained by M. Mercadier from ordinary gas lamps without employing lenses to concentrate the interrupted beam, by simply bringing the receiving disk near the source. Even a plate of copper heated to a bright red heat produced very distinct musical tones, which gradually died away as the plate cooled to a dull red followed by obscurity. The fact that when the receiving disks were coated with silver on the side next the light the effects were feeble, and that when coated with absorbent lamplack they were strong, would seem to tell against Prof. Bell's conclusion that the sounds were due to light. It is a curious fact that when the radiometer was first brought out by Dr. Crookes he intimated his belief that its rotation was due to the impact of light waves; but heat is now known to be the cause of the motion.

## Pictures by Telegraph.

It certainly is a fact that, by a recent invention, pictures of all kinds can now be sent by telegraph. Colors can not be transmitted, but all pictures which result from combinations of light and shade, such as photographs, steel engravings, wood-cut prints, India-ink sketches, pen sketches and crayon pictures are reproduced in five minutes, at a distance of 100 miles, with astonishing accuracy. Checks have been so faithfully copied by this process that the copy has been honored at the bank without a question. New York newspapers have been reproduced in Philadelphia entire—the image being sent by telegraph, and every faintest dot and blemish brought out on paper. We should be glad to tell the readers of the *Queen* exactly how this is done, but it is by a chemical process so complicated as to defy explanation in ordinary terms. *Nature* (the recognized authority in science in England), comes as near as possible, perhaps, when it says:

"In the transmitter the image was focused on a revolving cylinder, to which a selenium cell is attached. At the other end of the wire a platinum point presses against the surface of sensitive paper prepared by passing it through a strong solution of equal parts of iodide of potassium and water. The arrangement is such that the selenium cell, by intercepting the current, causes a white spot to appear on the receiver corresponding in shape and size to the picture focused on the transmitting cylinder. The experiments are as yet crude, but full of promise." This is not quite intelligent to the average reader, because the facts of the case call for scientific terms, and cannot be expressed in popular phraseology. But the important fact is that the pictures are sent; that photographs are admirably reproduced at a distance; and that, if the promise of the invention is fulfilled, a New York paper will soon be reprinted in Chicago on the very day, and perhaps the very hour, of issue. So much that is incredible has been made a fact during the last half century that he must be a bold man who ventures to place a boundary to the possible achievements of scientific ingenuity in this wonderful age.—*N. Y. American Queen.*

**EGYPTIAN ANTIQUITIES.—IMPORTANT DISCOVERY.**—The *Egyptian Gazette* says: "At the last meeting of the Egyptian Institute, on the 4th inst., a letter was read from Brugsch Pasha describing the recent discovery at Sakkarah of some inscriptions in two ruined pyramids. It is well known that the means for identifying the royal personages for whom pyramids were built are extremely scanty, but the hieroglyphics in question preserve the names of Papy, of the sixth dynasty, and of his son Merenra. They include also the private name of Merenra, which it seems was Horemhaf, but there is a slight doubt as to the correctness of this reading. The ruins have little of the pyramidal shape left, having been opened and destroyed at a remote period. Although they figure on the maps, both of Perring and Lepsius, neither of those explorers seem to have thought them worth examining. Funeral inscriptions of the time of the pyramid builders have not previously been found, and these, which are so far unique, are of the highest interest in the history of the religion. A mummy, believed to be that of the younger king, was taken out, and, we hear, was safely brought to Boolak, the only mummy of a king of the pyramid period yet discovered, with the single exception of that of Mycerinus, which is in the British Museum. We hope shortly to be able to offer some further details of this remarkable archaeological event."

**PURIFICATION OF EXPENDED LUBRICATING OIL.**—It is found that the purification of expended lubricating oil is not only practicable as a scientific process, but may be made a matter of economical advantage as well. One of the means resorted to for accomplishing this is to procure a tube of about 16 gallons capacity, supplied with one spigot at the bottom and one about four inches above; into this are placed 6½ quarts of boiling water, and there are then introduced 2,000 grains of chromate of potash, 1,540 of soda, 1,920 of chloride of calcium, and 3,840 of common salt. To this are added 50 quarts of oil to be purified; stir thoroughly for five or ten minutes, and after standing perfectly quiet for a week in a warm place, the clear oil is drawn off by the upper spigot. This plan is found to produce on the whole the most satisfactory result by the most simple means.

**SUBMARINE PHOTOGRAPHY.**—Improvements are said to have been made in submarine photographic apparatus, by means of which views have been taken near Glasgow, at a depth of ten fathoms underneath the water. One of these views, taken in the bay of that city, shows distinctly a sandy bottom, with a large number of boulders covered with seaweed, and an old anchor; also, in the shade, three mooring cables, belonging to small yachts.

**HEADS DIMINISHING.**—British heads are gradually growing smaller. Within the last quarter of a century the dimensions of the head have shrunk on an average one-seventh of an inch—at least so says a paper recently read before the Bristol Naturalist Society.

**SAXIFRAGE.**—Messrs. Garreau and Machelart, Paris, have extracted from the stems of the saxifrage, tannin, starch and a new proximate principle, hergenine, which possesses valuable medicinal properties, and may rank between quinine and salicine.

**SPANISH FLINT MINES**—Cor. Georgetown Gazette, April 30: G. H. Roelke & Sons are making all necessary arrangements for working their mine, which is a good one. They inform me that their clean-up for last winter amounted to \$900. With the rig they have now, they will clean-up five times that amount next winter. We hear encouraging reports of the Gopher mine, near Kelsey. Another good mine is Mr. Jensen's claim. It is reported that this mine has been handed to N. D. Burlington and G. Alderman, for \$10,000, \$5,000 down. If the Cal. W. & M. Co. would bring in a ditch on the ridge, scores of claims could be located and worked in this vicinity. The Parsons mine is found east of the shaft of the Parsons mine is now extended to the 2d level, and the work of drifting begun. We learn from good authority that Alabama Bar, on Middle Fork is to be worked on an extensive scale. The Cal. W. & M. Co. has a force of 33 men at work enlarging the Pilot hill ditch from Fraser flat to I. E. Terry's. Armstrong, Lee & Clark will commence sinking on the Au-

next mine next week. This mine is in Garden Valley district.

**CHAPARRAL MINE.**—*Mountain Democrat*, April 30: The Thursday John James completed his contract for running 50 ft of tunnel into the Chaparral mine. The tunnel is now 125 ft, at which point the ledge is large and strong, beautifully "ribbed," and occasional striae, made as the tunnel progressed, have proven that its entire length has been run in good milling ore. A contract for another 50 ft has been let to Mr. James, who will keep light along, and as there is still a strong "couge" of black galena in the face of the tunnel, there is every assurance that he will still be able to make rapid headway. A short time he will make a test, crushing of 100 or 200 tons of ore from their "Big Chunk" ledge.

## MARIPOSA.

**MINE AND HORRITON.**—*Mariposa Gazette*: We learn that there were new men representing capital, who were negotiating several mines in this section. Messrs. Robinson and Bell are engaged in opening and developing the old French mine, later known by other names. It is situated near the road leading from Hornitos to Indian Gulch. We believe that they have applied for a patent on this mine. There is an abundance of quartz, and here can be no doubt but what it contains strata of pay ore. The Washington is said to have struck a big thing in the 1400 level.

## NEVADA.

**BEAUTIFUL NGORITS.**—*Nevada Transcript*, April 23: "Six-finger hand," a Mongolian who has two thumbs on his right hand, sold at the Citizens bank yesterday two of the finest gold nuggets ever brought into the camp. They were worth about \$300. One of them originally weighed some 15 ounces, but had been cut into several pieces as if to disguise its shape. The Chinaman said he found them in a canyon near Omega while crisscrossing the gold had formed in crystallized quartz that afterwards became decomposed.

**SARGENT AND JACOBS' MINE.**—*Transcript*, April 20: For 50 or 80 ft in the drift of Sargent & Jacobs' gravel mine at Indian Hill, has been passing over a bar in the channel, and as a natural result, had a moderate amount of gold been taken out in the meantime. Within the past two days, however, signs have been encountered that show the end of the bar to be close at hand.

**NEW QUARTZ MINE.**—*Wm. H. Smith* is erecting steam hoisting works on the old Gallows Flat claim, adjoining the new cemetery on the northwest, and will be ready to begin sinking within the next 10 days. Some \$50,000 has been taken out of this ledge—known by many as the Eagle—above water level by the former owners. The incline is now down about 75 ft; Mr. Smith will sink 100 ft more (the machinery has a capacity of 500 ft), then drift. The ledge is a small one, from 8 to 14 inches, but of high grade, often going upwards of \$100 a ton.

**RICH COPPER ORE AT SPENCEVILLE.**—*Grass Valley Union*, April 23: It is reported that copper ore has been struck at Spenceville, in the county of Nevada, in this county, that will smelt fully 40% in copper. The ore is a carbonate found in the mine have ranged from 5% to 8%, and the copper has been extracted by the leaching process, rendering the ore friable by burning it in piles of about 80 tons each, and then obtaining a copper solution by leaching the burned ore in vats containing water. The copper from this solution is precipitated by being placed in large rotating tanks, capable of holding 3,000 gallons each, and is marketed as cement, which resembles a powder. The process is a cheap one, and although the ore has been of low grade it could be manipulated at a profit. If the ore in the mine is now to assume as high a grade as 40% it cannot be worked by the leaching process, but smelting will have to be substituted, which would require the erection of suitable furnaces.

## PLACER.

**NEW REDUCTION WORKS.**—*Placer Herald*, April 30: We paid a visit the other day to the Placer County reduction works, recently erected by White & Maltman, near the Turnpike, about a mile below Auburn, and found them in full blast. They are at present running on a batch of about 70 or 80 tons from the Julian, and as soon as the ore is through they have a lot to come in from the St. Patrick. Their appliances seem to be complete, and everything seems to work to a charm. They guarantee 85% of the fine assayed, but usually save more. The works have a capacity of 25 tons in 24 hours, which is probably sufficient for all present demands. Mr. Maltman has personal supervision of the works, and that is a thorough master of the business is true.

**HILL TUNNEL.**—We paid a visit last Wednesday to the scene of the mouth of the projected big Duncan Hill tunnel, and only a glance at the work thus far done is enough to convince one of the contemplated thoroughness and permanency of the enterprise. The fine large open cut leading to the face of the tunnel, with its even granite walls, indicates that it is made to last, and the size of the tunnel just being started, shows conclusively that it is intended for extensive use. Mr. E. W. Roberts is superintendent of this enterprise.

**CRUTCHER'S MINE.**—Crutcher keeps steadily at work on the quartz seams in his garden, and every little while makes some remarkably rich strikes. Last Wednesday he struck some of the richest rock he has yet had, and took out several hundred dollars in a few hours. Thus far his finds have been in spots, though the spots have been remarkably rich. The rock seems to be nearly horizontal and from 8 to 10 ft deep. There is a big, well-defined ledge near by, though he finds the gold in what seems to be a kind of float rock.

**THE IRON WORKS.**—The idea of iron reduction works in Placer county is now a reality. The furnace near Clipper Gap, under the supervision of Mr. J. M. White, is turning out pigs by the cord, and has every prospect for a successful summer's work. We have a sample of the iron, and though not a judge ourselves, those who pretend to be pronounce it first-class. It seems certainly to have a very fine grain, and a toughness far beyond the average of pig iron.

## PLUMAS.

**NEW TUNNEL.**—*National*, April 30: Frank Vere in forms us that he will commence tunneling operations at Crescent hill during the next week, and is confident that he is on the right track for a big bonanza in gravel. Crescent hill is on the southern slope of the mountain ridge, between here and Middle Fork, and is within a short distance of the celebrated Claremont Hill gravel mines.

## SAN DIEGO.

**TEST.**—*Colton Semi-Tropic*, April 30: The Pinacate stamp mill made a test of 5 tons of ore the other day, and cleaned up out of the lot over \$400. An excellent beginning, and one that is intended for extensive use. Mr. E. W. Roberts is superintendent of this enterprise.

## SHASTA.

**COPPER CITY MINES.**—*Cor. Redding Independent*: Under the judicious management of Messrs. Potter & Hall the extra mill is paying well. The new power is working splendidly, and is sufficient for 40 stamps having 120 ft pressure, and 20 ft suction. The wheel makes about 1500 revolutions per minute. A climb to the mines occupied an afternoon. The Jennie June shows up well, but is worked at a great disadvantage on account of the necessity of one so many times being hauled over a short tunnel will remedy that. Work is being done on the Bully Hill and the mines are good, though no ore is being taken out at present. The finest tunnel in the hill is at Northern Light. It is greatly to be hoped that this mine may prove to be all that is anticipated, as a mill will be at once erected. Copper City is remarkably healthy. The two stores seem to be doing a good business. A reduction mill is being put out of the localities, and stopped at Furnaceville for dinner. It seems a pity that so fine a mill should remain idle. Furnaceville is almost deserted.

## SIERRA.

**GOLD BLUFF.**—*Mountain Messenger*, April 30: The gold mill cleaned up \$6,000 the last run, although working

to a great disadvantage. The owners are now in condition to get rock more advantageously and cheaply than before. It is, we learn, the intention to put up a larger mill very soon.

**THE WILBURN CON. CO.'S** shaft was down among large boulders, the last we heard, and in fine-looking gravel. It was supposed they were near bedrock. The quartz gravel is steadily becoming coarser, and is 9 ft deep in the shaft. One boulder was 5 ft thick. The prospects are now very encouraging.

**SUBSTR.**—All Bits and partner took out a very large piece of gold a short time ago in their diggings below the 21 mill.

Work is being prosecuted on P. Grant's claims in Cariboo ravine.

**BONDED.**—The Bush quartz mine, below Loganville, is said to have been bonded by S. V. Mooney for \$50,000. It is also rumored that work will be immediately commenced to develop it.

## TRINITY.

**HYDRAULIC ELEVATOR.**—*Trinity Journal*, April 30: Mr. John Yule, superintendent of the McGillivray mines, has returned from his recent visit to Butte county, where he went to see the improved hydraulic gravel elevator in actual operation. He is enthusiastic in praise of the machine, saying that it does his work easily and well, and is a great improvement on the old ones. The strong probabilities are that Mr. Yule will have an elevator at work in this county in a very short time; and if it works as well as reported, many will soon be introduced here.

**SPLENDID PROSPECT.**—From parties who recently visited the locality we learn that the recent strike made by the Gibson Bros., bids fair to prove an extensive one. The rock continues rich at a depth of 10 ft, and the ledge shows a width of 4 ft. All the rock taken out will pay to work, there being no waste whatever. The mine is on the Shasta county side of the Deadwood and French gulch divide.

## TUOLUMNE.

**CHLORINATING.**—*Tuolumne Independent*, April 30: The superintendent of the Olsen mine has gone to San Francisco for the purpose, it is understood, of negotiating for the putting up of chlorinating works for the roasting of the sulphuret ore developing in such large quantities in the mine. Gilkey, tired of hauling ore, has sold his buildings and retired to his home among the mountains. J. Olsen, with his magnificent teams, now does the hauling, and is capable of supplying them with 30 tons of ore a day, if necessary.

It is reported, on good authority, that the Ferguson mine has been sold to a company in London. The strike in the Rife mine is not so extensive (as yet) as the San Francisco man, whom Hunter gave a \$2 specimen to, made it out to be; but he hopes soon to come to the main body of gold. Chris Schultz has struck very rich ore in the Lynch mine, above Sonora, and upon which he is building a mill.

**NEW MILL.**—*Union Democrat*, April 30: Mr. H. H. Eames is erecting a 5-stamp mill on the Street & Groes mines, which he has bonded at Tuttle town. There is a lot of enterprise and thrift about Mr. Eames' works which betokens permanence. A new boarding-house and several dwelling houses are to be put up soon, which, with the half-dozen buildings recently finished, will make quite a town. The buildings are all neatly whitewashed, everything looks clean and workmanlike.

## NEVADA.

### WASHOE DISTRICT.

**SIERRA NEVADA.**—*Enterprise*, May 2: On the 2500 level winze No. 2 has been sunk and timbered 20 ft; total depth, 57 ft. The north lateral drift on the 2500 level has been extended 40 ft. During the week we have raised 194,400-2000 tons of ore.

**MEXICAN.**—On the 2500 level the joint Union Consolidated winze has been sunk and timbered 10 ft, and a hoisting engine has been placed at the top. The joint Ophir east winze has been sunk and timbered 6 ft and the 2500 level has been put in.

**GRINA.**—On the 2500 level the joint California winze has been sunk and timbered 17 ft, the joint Mexican east winze has been sunk and timbered 6 ft and the 2500 station set has been put in. A pump is being put in at the 2700 station. Repairing the incline at the 1900 station.

**CONSOLIDATED VIRGINIA.**—During the past week 414 tons of ore, assaying \$18.65, have been extracted and sent to the mills. On the 2500 level the progress in the Best and Belcher upraise was 17 ft. On the 2500 level the joint California west drift to the C. and C. shaft has been extended 28 ft, and the joint California east drift from the C. and C. shaft has been advanced 23 ft.

**UNION SHAFT.**—The shaft has been sunk and timbered 9 ft during the past week. Are repairing the shaft between the 1600 and 2500 stations.

**HALL & NORCROSS.**—The west crosscut on the 2400 level has been advanced 46 ft. Its face is a mixture of quartz and porphyry. A section of pump-rock has parted, but it will be repaired by to-morrow.

**UTAH.**—Since last report the incline has been sunk and timbered 12 ft; total distance below the 2150 level, 177 ft (on the slope). The South drift, on the 2150 level, has been extended 22 ft.

**UNION CON.**—On the 2500 level the joint Mexican winze has been sunk and timbered 10 ft, and a hoisting engine has been placed in position at its top. The joint Sierra Nevada winze has been sunk and timbered 18 ft.

**ALTA.**—During the past week have sunk and timbered the shaft 31½ ft; total depth, 1,971 ft. No change in the geological character of the ground and no increase of water. All the material for the bobsis received and most of it is in place.

**ALTA.**—During the past week 498 tons of ore, assaying \$18.55 per ton, have been extracted and sent to the mills. On the 2500 level the joint Con. Virginia west drift to the C. & C. shaft has been extended 23 ft, and the joint Con. Virginia east drift from the C. & C. shaft has been extended 23 ft.

### CANDELARIA DISTRICT.

**NORTHERN BELLE.**—*True Fissure*, April 30: The first and second levels look finely, and are producing the usual quantity of ore. The eleventh or adit level still continues to hold its own remarkably well. All the stops are yielding as well as ever, showing no diminutive either as regards quantity or quality of ore produced. There is now being extracted and sent to the mill 88 tons of ore daily. Both mills are running steadily. The bullion shipments for the week ending April 27, were \$98,407.37.

**MOUNT DIABLO.**—The north crosscut gives good ore from the raise, though mixed with waste. On the second level the west drift is in low grade ore, advance 10 ft. The winze from the ft of Callison winze will be connected with the west drift on the third level in a few days.

### ESMERALDA DISTRICT.

**WHAT IS GOING ON.**—*Herald*, April 30: The feeling existing here and abroad in regard to the mines of this camp is flattering indeed, and the growing interest gives us the greatest encouragement that the district is at last in a fair way to get what it has long needed and never had—a fair show, a thorough prospecting. The developments made in the Centennial and Cortez, and the appearance of ore from the Silver Hill, prove conclusively that the precious metal is here in abundance, and all that is needed to make Aurora bloom again is work and milling facilities. We are going to have the mills, and work is now being prosecuted from Silver Hill to New Esmeralda, a distance of 5 miles. For years the mines have lain almost idle, and of course nothing was developed, but a little work has made a vast change in the appearance of things. It is not till the mill gets up a mine that is second to none on this coast—the Cortez. It has proven the New Esmeralda a bonanza. It has shown the Centennial to be fabulously rich, and demonstrated wherever work has been done that fair to good milling ore abounds everywhere. Such being the case, we expect to see mines in active operation from one end of the district to the other before the summer is over.

## EUREKA DISTRICT.

**REMOVED STRIKE IN ALBION.**—*Eureka Sentinel*, April 23: A rumor has been afloat about the streets for several days of an important find by the Albion Co. As the story runs, the Richmond, just before mentioned, had discovered an immense ore body in a drift in what is known as Albion No. 1. Ascertaining that they had crossed over the Albion line, they withdrew and plugged up the drift. In making surveys for the purpose of the late trial, the Albion people are alleged to have discovered this blind drift and explored it to its full length, with the result already indicated.

### GRANTSVILLE DISTRICT.

**BROOKLYN.**—*Grantsville Bonanza*, April 30: In the Brooklyn a fine body of high grade ore has been developed. This is the same body of ore that was only broken into some time ago. The old stops are still as productive as ever.

**THE ALEXANDER.**—The Alexander stopes look bigger than ever, and a large body of ore has been uncovered in the back, between Nos. 5 and 6. The water has increased some during the past week.

**THE LEFFLER.**—Very fine indications are now appearing in the Leffler mine, with every prospect of uncovering a fine body of chlorite at any moment.

### OSCEOLA DISTRICT.

**WORK.**—*Pioche Record*, April 30: Work will be pushed ahead at Osceola this summer. Godhe & Hampton, who own 20 placer claims in that district, intend bringing water into their claims and working them.

### PIOCHE DISTRICT.

**ORK.**—*Pioche Record*, April 23: There was a rumor circulating around during the week that ore from the black ledge had been put through the furnace and that it proved good smelting ore and yielded well in silver. This is all a mistake. There was a ton and a quarter of base ore from the Raymond & Ely, which resembled the ore of the black ledge very closely, which was put through the furnace, and caused the report. There is now about 40 tons of black ledge ore at Bullionville, and 20 tons more in the ore-house here, but there is not any likelihood of the Bullionville smelting works touching it as long as they can get all the high-grade ore they can handle.

**BULLION.**—*Pioche Record*, April 30: \$6,288.74 in bullion shipped by Wells, Fargo & Co.'s Express during the week.

This mill of the Meadow Valley Co. is now running steadily and turning out considerable bullion.

The train made one trip to Bullionville during the week, bringing down a load of ore. This cleans up pretty much all the ore extracted by chloriders, and the cars will not probably make another trip for a week or two.

**DAY COMPANY.**—The work at the mine is being pushed and everything is being put in such shape that large amounts of ore can be extracted and hoisted at short notice. There are large quantities of ore and charcoal being piled on the dump of the furnace at Bristol.

## ARIZONA.

**CLOSE ITEMS.**—*Silver Belt*, April 30: Mr. Winn has made a very important strike, on a new ledge, within a short distance of the Emmazetta mine. He tells us that the ledge is large and well defined. J. C. Lennon has returned from New York with the intention of fixing up matters for the Nugget Co., and resuming work on the mine. The Old Dominion Copper Co. are going to erect a 30 ton smelter at once. The Supt. has secured one of the best furnace sites in the district. He has plenty of water the whole season, and wood is within three miles. The smelters will be so situated that the ore can be run in cars directly to them from the mines. George Scott, of this place, has sold to Thomas H. Mason, of Boston, the Interceptor Copper mine, one mile north of Globe, for \$7,000. George Scott will resume work on the Pioneer mine during the first of the coming week. The large mine is looking well, and the owners contemplate increasing their working force. The Mineral Creek mine is about to be handled properly at last. We know from others that there is a very large ledge on the property, and we are of the opinion, based upon our knowledge of the district, that careful prospecting on it would develop good paying ore. There are over 200 tons of ore now on the dump. It would seem from the number of new strikes being made that prospecting is only in its infancy in this district. We have recorded several this week, and the latest reaches us just as we go to press. Dr. McDonnell has struck a 6 ft vein of ore, on the Illinois location, that goes 50% in copper, and is rich in silver also.

**COPPER.**—*Tombstone Nugget*, April 30: The Clifton copper mines are reported to be increased in richness. Large quantities of very high grade ore have recently been shipped. The first of the coming week. The large mine is looking well, and the owners contemplate increasing their working force. The Mineral Creek mine is about to be handled properly at last. We know from others that there is a very large ledge on the property, and we are of the opinion, based upon our knowledge of the district, that careful prospecting on it would develop good paying ore. There are over 200 tons of ore now on the dump. It would seem from the number of new strikes being made that prospecting is only in its infancy in this district. We have recorded several this week, and the latest reaches us just as we go to press. Dr. McDonnell has struck a 6 ft vein of ore, on the Illinois location, that goes 50% in copper, and is rich in silver also.

**SILVER KING.**—*Bulletin*, April 30: The Silver King is pouring out a Silver current sure enough. She has shipped over \$75,000 worth of bullion during this month, and will ship over \$30,000 more before the month closes. Globe City, or rather Gila county, has been shipping extensively also. Altho George reports having discovered some valuable springs in the upper San Simon valley, about 25 miles from Cave creek, affording sufficient water for 1,000 head of stock, and that the region round about is entirely free from brush or shrubs and is eminently adapted for sheep.

### IDAHO.

**WOOD RIVER.**—The following notes are from an interview with Mr. Mute (just returned from Wood River), in the Salt Lake Tribune: The climate is all that could be desired for a northern country. The snow was off at Bellevue, and up the river it was clear of snow for 12 miles. As a mining country I think it is the best I ever saw in my life. It is not overrated as far as mineral wealth is concerned. The labor market is over supplied, but the field is great for good prospectors. The need of the country is capital. I think the mines will furnish ore enough to keep the smelters going. There is one smelter lying on the roadside at Bellevue awaiting lumber. It will be put up soon as the saw mills can furnish the material. There are merchants enough to do the business at present, and the opening is not good. Money is scarce and the business credit is a good deal tighter than it was. Smelters are built and the mines more fully developed. Bellevue is the leading town now, containing about 400 citizens and 100 or 200 houses. It will grow as fast as material can be procured. There are other towns up the river which have bright prospects, being nearer the mines than Bellevue. There is a big rush; about 400 have gone by the Kelton stage and about as many by the Blackfoot route. A great many are going in by their own conveyance. The people think the rush is too great for their present facilities. They expect a second Leadville as soon as they can accommodate the people. Capital is what the country wants to make it one of the finest mining regions on the Pacific coast. The mines are rich and they all improve at depth. I noticed a great deal of ore out, and shipments to Salt Lake City will begin in a short time. The roads are improving and Salt Lake can look for a large amount of rich ore from Wood River. Take it all in all, Wood River is a good country, and as a mining country is all that it has been represented.

### MONTANA.

**STRIKE ON THE MOULTON.**—*Inter-Mountain*, April 23: Yesterday the force of men employed in excavating for the Moulton mill, struck one of the largest bodies of ore ever opened up in the district. The ledge, which was

partly covered up by surface deposits, was to-day demonstrated to be a total width of 40 ft. It appears to be divided into two sections, separated by a porphyry horse about two ft. in thickness. The north section is a black manganese, the assay value of which is unknown at the present writing, and the other shows ore identical in appearance with that taken from above the water line in the Alice. The quality is exceptionally good. An assay made yesterday returned 388 ounces in silver and 14 ounces in gold—a total valuation per ton of \$532 40. The ore across the entire width of the vein is of good workable quality, and Superintendent Bowers has been ordered to strike it in the Butte, are in high splits. It is likely that a shaft will be at once started to prospect the bonanza.

## NEW MEXICO.

**SILVER IN A WELL.**—*Tucson Citizen*, April 29: The railroad company in boring for water at Lordsburg, New Mexico, made a mineral discovery of wonderful promise. The well was dug and cribbed for 90 ft from the surface, and quite a ledge of excellent ore was developed. From this point the 8-inch drill was set at work and run down 450 ft, bringing up at that depth in a vein of almost pure silver, a sample of which was sent to the Citizen office. The well was abandoned and privilege given to the railroad employees at Lordsburg to locate the singularly discovered mine, which they did not hesitate to do at once. The lucky boys fully expect to find an immense bonanza in the bottom of the well, and their spirits have correspondingly risen.

**BLACK RANGER.**—*Cor. Nevada Transcript*: I have been in the mines about six weeks and have examined all the principal locations. The claimed mineral belt lies in the foothills on the eastern slope of the Black Range—a range of tolerably high mountains some hundred miles or more long. The mineral belt is about 40 miles long and runs from one to five miles wide, and abounds in quartz ledges running to every point of the compass and dipping at every angle. The country is well watered by many streams, while the hills, mountains and valleys are covered with fair to good timber and a great abundance of firewood. The principal timber is yellow pine, spruce, juniper, black walnut, white ash and nut pine. The whole country abounds with fine grazing all the year. The climate is certainly excellent, with the genuine California nights. The mines? Well there is the rub. I have seen no mines since I came to this camp. Neither do I see any prospects that promise anything for the future. While many of the hill tops show ledges, the heads of the creeks show none, while the croppings show the lower workings are innocent of the contaminating lacer. But talk with a "wanderer" who is the happy possessor of some hundred locations, and Arapahoe and bluish for lack of proficiency and Alladin would be a pauper. Tell all the boys to come to the Black Range. There is some very good looking country south and west of here, and I have no doubt there are also some good mines there.

## OREGON.

**BLACKWELL.**—*Oregon Sentinel*, April 30: Barksdale & Cunningham have struck very rich quartz in their tunnel in the Blackwell district. The quartz, which is quite yellow with free gold, was struck in the top of the tunnel, is nearly a ft wide, and the owners feel sanguine that they have a valuable pocket. The rock just discovered yields, in a hard mortar, \$24 to the pound.

**PROSPECT.**—*Supt. Ennis*, of the Sterling hydraulic, has picked off about acres of very rich ore, and the present season, with a good prospect for over 2 months' more of a full head of water. Work on the ditch extension is going steadily on, and next winter 3 giants will be used.

**YELMINE.**—The claim of Saltmarsh, Klum & Co. is evidently yielding well, as last week; 2 pieces of gold were picked up in the ground sluice, one weighing \$14 and the other \$30. Work of cleaning up in the mine has not yet commenced.

**GOOD YIELD.**—The claim of Hosmer, Lance & Duffield, on Foot's creek, must have some rich pay in it. It will average 20 ft in depth, and every cubic ft will yield 25 cents. Only a quarter acre has been worked off, yielding over \$10,000.

**NOTES.**—Miners on Coyote creek have generally cleaned up, with fair returns for their labor. John Montgomery has cleaned up \$1,600 for the season's work on the ground leased from the Dean Bros. at Willow Springs. The large hydraulic mines of the Blue Gravel and English companies, at Galice, have discontinued piping on account of failure of water. The Schump tunnel is still being vigorously pushed ahead. It is yet in hard rock, with about 50 ft to run before the lode can be struck. Green Bros., of Galice creek, are still engaged on a new tunnel, but are continually washing quartz which yields from \$10 to \$50 per ton. Alex. Watts, of Williams, is working a new extension of operations for the season. He runs a small hydraulic, and averaged \$12 per day for the season. Sturgis & Beckner are now engaged in cleaning up on Jackson creek. Their ground is panning out well, and within the past 2 weeks they have picked up about \$300 on the hedrock. J. T. Layton, of Applegate, has sent for 1,500 ft of 15-inch hydraulic pipe, and will lay down the old belt. The new belt will be laid down in a new manner, and to be yielding very satisfactorily. A new tunnel to strike the Holman ledge, between the branches of Jackson creek, at a greater depth is spoken of. Were that hill in Nevada or California it would have been honeycombed with tunnels long ago.

## UTAH.

**THE CARBONATE.**—*Southern Utah Times*, April 23: From this mine we have a very favorable report, which is to the effect that the heat ore ever found in the mine has been taken out of the raise above west 4 on the second level during the past week. At the concentrating works of this company the new East Canyon concentrator is working very satisfactorily, according to President Bigelow's statement, is extracting 20 ounces silver and 10% of lead from the slimes which are too fine to work in the dry machines. By means of the saving process applied to the machine by Supt. Farnham, very little valuable water is wasted.

**SOME SHAUNTE MINES.**—Average samples of ore from the Gallinipper, Magnolia and Rose mines, owned by J. R. Lindsay, were assayed by Mr. A. S. Bigelow last week, and found to contain 100 to 150 ounces silver and from 5% to 6% lead. There is more than 125 tons of this ore on the dumps at these mines.

**NICKEL** plating of machinery is now becoming quite common, even with large pieces. In England, the other day three large cylinder covers for enclosed engines were nickel-plated and polished, the largest cover weighing 1½ tons, and being 6 ft. 6 inches in diameter.

**MILLING ORES.**—We are unavoidably compelled to omit from this issue the continuation of Mr. Rothwell's article on the cost of "Milling Silver Ores in Utah and Nevada." It will appear in our next.

**AMONG THE CITY OF CHESTER'S** steerage passengers Sunday, at New York, were 1,099 Irishmen and women. This is the largest number of persons ever brought from that country at one time, and by far the greater proportion of these are members of the Irish Land League.

The consolidation of the city and county governments at Virginia and Gold Hill, Nev., was effected on Monday without opposition. There was much talk of contesting, but all ended without any serious result. Taxes on all property (including mines) in this county will be less than heretofore.

### The Miner's Soliloquy.

To go or not to go; that is the question;  
Whether 'tis wiser in the honest miner  
To work persistently on fissure veins,  
Or load a burro and absquatulate,  
And by migration quit them. To go, to skip—  
That's all—and by yamooing say he strikes  
The trail that leads to wealth and fills his purse  
With glittering lucre; 'tis a consummation  
Too gorgeous to expect. To go, to skip,  
To toll, perchance to fall—aye, there's the rub;  
For in that untrodden field what woe may come  
When he has shuffled off the last red cent?  
What man would pay the gorgeous royalty,  
Or bear the pangs of minimum assays,  
When he himself might his own fortune make  
With pick and shovel? Who would those trials bear?  
To toll and wrestle with a doubtful lease,  
But that the fear of running out of funds,  
Before he strikes the contract, curbs his will  
And rather make him work the streak he has  
Than tackle one that may be twice as lean.  
Experience makes philosophers of all,  
And oft a little wholesome hesitation  
Bears fairer fruit than reckless resolution;  
Thus enterprise needs scarce and silver  
Are hurst in the bud. Soft, you now,  
Angelic reader. Nymph of the hush-house table,  
Be all my wants remembered!

—Tombstone Epitaph.

### Annual Expenditures on Claims.

The following facts regarding a recent dispute at Tombstone, Arizona, will be of interest to mine owners:

"The Boh Ingersoll claim was located September 10, 1878. The owners did \$100 worth of work in 1878, immediately following the location, but did not do any work in 1879, being under the impression that the work done in 1878 carried them through the year 1879. This would have been a correct conclusion for them to draw had not Congress passed an act on January 22, 1880, providing that \$100 worth of work should be done within each calendar year. As no work was done in 1879, this left the Boh Ingersoll ground open to relocation, a chance that was eagerly jumped at by certain parties in Tombstone, and the ground was located by half a dozen rival claimants. The Boh Ingersoll people contended that Congress had no power to pass a retroactive law; that their claim having been located in 1878 could not be effected by a law passed in 1880. The jumpers claimed that Congress had absolute power over the mineral domain; that the miners had only a possessory title, which could be defeated at any time by failure to comply with Congressional laws, and that as long as the title was in the Government, the Government could make any kind of regulation it chose in regard to the land. The matter was finally referred to the Commissioner of the General Land Office. A copy of the Commissioner's letter from the original in the hands of one of the lawyers in this case is as follows:

GENERAL LAND OFFICE,

WASHINGTON, D. C., February 23, 1881.

Sir: I am in receipt of your letter of February 8, 1881, in regard to the expenditures necessary to be made on the Boh Ingersoll lode. It appears that the Boh Ingersoll claim was located in September, 1878, and that \$100 worth of work was done by the locators during September, 1878. No work was done in 1879 by the locators or their grantees, nor in 1880, until December 11th of that year. Prior to that date, viz., during August and September, 1880, the ground was relocated by the Pinto, Moonlight and Midnight claims. On December 11, 1880, the locators of the Boh Ingersoll took forcible possession of the claim, and are now holding it. By the amendment to the mining act, approved January 22, 1880, it was provided:

SECTION 2. That Section 2,324 of the Revised Statutes of the United States be amended by adding the following words: *Provided*, That the period within which the work required to be done annually on all unpatented mineral claims shall commence on the 1st of January succeeding the date of location of such claim, and this section shall apply to all claims located since the 10th day of May, A. D. 1872.

Whatever work, therefore, is done prior to the January succeeding the location of the claim, cannot be considered or credited to the year following such January. In the present case no work was done during the calendar year of 1879, and, as just remarked, expenditures before that date cannot be considered. The mine then became subject to relocation on January 1, 1880. If it was actually relocated before the original owners resumed work, such relocation is good, and the claimants of the Ingersoll, in taking forcible possession of the claim, were trespassers, and would not, under the present rulings, be recognized by this office.

Very respectfully,

J. A. WILLIAMSON, Commissioner.

It will be seen by this letter that the Commissioner holds that the annual expenditure must be made within each year, commencing on January 1st, and any expenditures made before January 1st do not count. As this is the ruling by which the Department will be guided in the future, owners of all mines located since May 10, 1872, should be sure that their annual work has been done within each year. If it has not been done they should rectify the error at once by a new location.

It was supposed that the decision of the Commissioner would settle the question, and so it did in the minds of good lawyers. But the Boh Ingersoll people laughed at it, and announced their intention to contest the Commissioner's ruling in the courts, and put fighting men on their mine. After a few days of warlike threats better counsels prevailed, and they acknowledged the justice of the Pinto, Midnight and Moonlight claims, and settled with the owners, or, in parlance of the honest miner, "took them into camp."

### Volatilization of Gold.

It has been stated by some authors that there is never much loss of gold in roasting ores, unless the roasting is performed too rapidly, and that the addition of salt makes no difference in this respect. I differ with them on this point, even when the statement is supported by so formidable a name as that of Plattner. But I think that illustrious chemist would yield to the logic of a pecuniary loss of \$3,000, especially when hacked by other facts.

When I first entered on the business of gold chlorination on a large scale, I had a class of concentrations to treat which, while consisting chiefly of iron pyrites, and presenting no visible peculiarity, had nevertheless baffled many old operators, a fact of which I was not at the time aware. The ore was roasted in a three-hearth reverberatory furnace, with the addition of from 1% to 2% of salt, on account of the presence in it of a considerable quantity of silver.

I was surprised to find that although the assays of the tailings were satisfactory, the gold, when collected, fell alarmingly short of the results which I had guaranteed, and I was of course obliged to make up the deficit.

Relying on the statement referred to, which I found in the only handbook on the subject within my reach, and being then a novice in this branch of metallurgy, I did not dream that a serious loss was taking place in the roasting furnace, especially as I had an expert metallurgist in reduced circumstances employed on the roasting, who had no more suspicion of the truth than I had.

Finding that I was sustaining some loss by inadequate room for the gold solution, and having consequently to draw the liquid from the gold-tub too soon after precipitation, I thought that I should find the whole loss to be in the leaching and precipitating department, and each time that an improvement was made, expected better results, so that I was led on from trial to trial, until the total loss reached the sum named.

I am not quite certain that I should ever have discovered the truth, but for the following accident: One day, I so far checked the draft of the furnace as to cause some fumes to come through the air holes and working doors, and a yellow sublimate on the masonry attracted my attention. On examination I found the sublimate to be very rich in gold, although there was none too to be seen in it by the most careful washing. It also contained iron perchloride, and copper chloride, with some lead and other substances. This aroused my suspicion, and I at once did what I ought to have done sooner.

Knowing that the material could be roasted with little or no loss, if no salt was used, because some assays had been made in that way, I weighed two half ounces of a sample, and roasted them in the muffle side by side, under precisely the same conditions, except that to one of them I added 4% of salt. The roasting was purposely pushed to an extreme as to heat and time, and when the two tests were assayed, under exactly similar conditions, that which was salted was found to contain less than half as much gold as the unsalted one.

I then took some light fluffly sublimate from the due of the roasting furnace, an assay of which gave me a value of some \$600 per ton, chiefly gold. The quantity of this material was, however, very small, and the bulk of the matter in the dust chamber was not much richer than the average of the ore treated, a circumstance which indicates that the gold was actually to a great extent volatilized in some not easily condensable form. I also found that the ore sustained a loss of weight in roasting, equal to about 18%, consequently the roasted ore ought to have been more than 18% richer than before roasting, which was not the case.

If this is not considered to be sufficient proof that gold may be volatilized in the roasting of some ores with salt, the deficiency is supplied by the fact that, as soon as I made the necessary change by reserving the salt until the nearly dead roasting of the ore was finished, not only did the roasted ore assay 20% richer than when raw, but the yield overran my guarantee, while the tailings nevertheless contained considerably more gold than before.

The moral of this is, never to neglect any precaution in the way of tests and assays, nor to place implicit reliance on rules laid down, or inferences drawn by others who have worked under different conditions.

I afterwards found that a very small quantity of salt, not more than three lbs. to the ton, might be mixed with the crude ore without detriment to the gold, and with decided advantage to the extraction of the silver.—*Aaron's Leaching Gold and Silver Ores.*

### Altar, Mexico.

Considerable attention is just now being turned to the mines of Altar, Mexico, especially by people in Arizona. Altar is a mining town of about 2,500 inhabitants, and was formerly called Santa Gertrudis del Altar, and it is sometimes now called Guadalupe. It is watered by a small stream called Rio de la Asuncion, branching from the Altar or Magdalena river. The stream is insufficient for irrigation in the dry season. The town is situated near the banks of the stream upon a plain about 80 miles northeast from the gulf coast, and about 100 miles from La Libertad, which is located south-east on the coast. The plains on the west are dry and sandy, and are a part of the great Col-

orado desert, which extends down the coast near Lohos, about 50 miles distant in a southwest direction. The discovery of mines of gold and silver in the vicinity of Altar gave it a great impetus at one period in its history. It is mostly built of adobe houses. The town is garrisoned by a few soldiers, and the streets are irregular. East of the town are situated ranchos exceedingly fertile and abundantly watered. The place is distant from Santa Cruz about 120 miles, which lies in a northeast direction by way of Magdalena and Arispe. Santa Magdalena is about 70 miles distant. The latter town is also called San Ignacio, and is located due east of Altar in a beautiful valley. The number of inhabitants is about 3,000. The stage connects at Magdalena with Hermosillo on the southeast and thence to Guaymas, and on the north with Tucson by way of Tombstone and Benson, Arizona.

### Nitrate of Soda.

The discovery of nitrate of soda near Brown's station, Nev., may lead to results vastly important to the Pacific slope and to the country at large. This valuable salt has been found in extensive beds only in the province of Tarapaca, among the hills which skirt the coast of Peru. These beds extend over a territory of 150 miles. The hills are covered with a light, sandy marl, mixed with minute fragments of shell. When this covering yields and cracks beneath the feet, it indicates the presence of nitrate of soda. On digging a foot or two the salt is found, overlaid usually by a stratum of common salt. Portions of this nitrate of soda are of a pure sugar-like whiteness, other portions being colored reddish brown, lemon yellow and gray. A large portion of the provincials find employment in extracting and refining the salt, which is shipped from Iquique. In 1837 the exportation aggregated 120,000 quintals, England consuming two-thirds and France one-third. The nitrate mines have long been the chief wealth of that section of the country, and their importance can well be imagined, when it is remembered that the Peru-Chilean war grew out of disputes over the revenues of those fields.

Some time ago the State Mineralogist of California, Mr. Hanks, received samples of crystallized nitrate of soda from this county. Tests prove the salt to be of good quality and exceedingly valuable. Mr. Hanks advises prospecting the desert regions, where evidences of volcanic action are present, or where alkalies are plentiful. The test is simple and admissible of no mistake. The suspected crystal or salt should be reduced to a powder, and intimately mixed with an equal proportion of charcoal. This, when placed upon a heated iron, a red hot shovel for instance, will deflagrate—will flash like powder—the fire running from grain to grain in a similar manner. The compound is powder minus sulphur. Where it is suspected that the earth is strongly impregnated with the nitrate, take a kettle and fill it two-thirds full of the earth and the remainder with water. Heat it, stirring the while, and when thoroughly mixed and heated, so that the water will have become saturated with the salt, allow the solution to settle. The liquid poured off, the mud will contain the salt, which is secured by evaporating. The crystal is then tested as before. The test is accurate, and may be applied by any one without apparatus.

A good nitrate mine is more valuable than a gold mine. The cost of extracting the salt at Tarapaca, where it is principally secured by the process of lixiviation above described, is as follows: Reckoning for each 100 lbs., labor is set down at 62 cents; fuel, 38 cents; tools and powder when blasting is necessary, 12 cents; transportation to Iquique, 75 cents, a total of about \$1.87.

In quantity, the salt sells for about \$8 the hundred lbs. The profit is apparent. The uses to which nitrate of soda is put are numerous. It is substituted for nitrate of potash—saltpeter—to which it is closely allied, in preserving meats as in curing hams, pickling pork and corned beef, the manufacture of nitric acid and various other purposes. Owing to its delinquent properties, it has not been employed in the manufacture of gun powder, although it is not known but in some varieties of explosives it might be employed, if indeed it is not already. Careful search over the regions given over to arid plains and lava beds may result in the discovery of hitherto unexplored mines of wealth.

### Stockholders' Rights.

It is safe to conclude that when a mining company declines to make known the condition of its property or affairs to its stockholders, or to the public, there is something afloat that is not what it should be. A mining exchange holds the following sensible view of the rights of stockholders: "The stockholders of a mining or other stock company have just as much right to know all about the company's affairs as has the president, secretary or any other member of the organization. Every stockholder in a mining company is a member of the company, just as surely as is every owner in a commercial firm a member of that firm. It is true that the stockholder in a mining company votes for the officers of the company, and in doing so authorizes the officers to act for him in their several official capacities, but no further. The officers of a mining company properly are the servants of the company, and have no more right to know what is taking place at the mines, or in other departments of the company's affairs than has the smallest stockholder."

### Swelling the List of Preserved Products.

It is gratifying to see that the list of California preserved products is constantly increasing. There are a hundred things which form items in the great commercial wealth of the world, which can be produced here, and though the revenue from each may be comparatively small, the aggregate will be large, and our income as a State increased to that amount. Fortunately the day of small things is advancing in California, and the reign of the little economies will enrich the mass of the people far more than the era of great speculation through which we have passed. These remarks are suggested by an item in the Los Angeles Express, which gives information obtained from a representative of the San Jose Packing Co., who is now in the southern counties. It is stated that this house has been experimenting for the past five years on the preservation of the citron and other similar fruits of commerce, and they are now ready to put their products on the market. They have erected a building with tanks and apparatus at large outlay and brought a man from France to superintend this branch of their work. They will use citrons, pinalos, bitter oranges, Chinese lemons and that class of fruits which our horticulturists have been in the habit of considering worthless, paying therefor \$1 per hundred lbs. in Los Angeles. They also expect to manufacture *glace*, or candied almonds, walnuts, apricots and cherries. The almonds and walnuts are picked when about half matured—when they can be readily sliced through with a knife—and pickled, shell and all. The San Jose Co. have an order for 20,000 lbs. of these products to be shipped to London, and they expect to employ their new apparatus in this work almost exclusively during the coming season.

### Mining on Snake River.

Mr. L. B. Foster was in town on Saturday, and informed us that his company, composed of Charley Haines, formerly division agent on the overland road, J. W. Wilson, John Irvine and himself, have been mining on a bar on Snake river, four miles below the old Dorsey ranch, and were making \$25 per day to the hand. They let a couple of boys go on to a portion of the bar on the claim that was what they called a high bar, and rock five days for a little grub stake, and they took out \$40. The water they had been using was from an irrigating ditch, which belongs to Isaac Culp, the present proprietor of the Dorsey ranch, and he is now using the water, which lets their mining out in that place for this summer, but they have equally as good a bar on the other side of the river, below the mouth of Castle creek, where they are now going to mine, and will put in a larger machine for saving the gold than they had up at the Dorsey place, and expect to do better than they have been doing.

Mr. Foster says the gold is a little coarser than it is up at Salmon Falls, and they're trouble has been, in all the Snake river mining, to save the gold. He thinks that all the mines on this river have improved their machines for saving the gold, and they are doing better and will take out more gold this season than they have heretofore. The company will take water from Castle creek to work their lower mines, and will have plenty of it. They own a large bar claim of 160 acres on this side of the river, nearly opposite Castle creek, that will pay equally as well as the Dorsey claims.—*Idaho Statesman.*

### Silver Belt.

Prospecting in the vicinity of Iron City, about 40 miles north of the Reef, Utah, has been quietly going on for some weeks, and although reports have been frequently received from those who have struck prospects, but little attention has been attracted to the district, owing to the fact that it was abandoned some years ago. Recent developments, however, prove the old-timer's theory incorrect, and the most flattering reports are now being fully substantiated by specimens of the rock and the certificates of well known assayers.

From Mr. J. D. Hickox, who returned to the Reef yesterday, we learn that at a meeting of the miners and prospectors held last Saturday a new district was organized, to which the name of Silver Belt was given, and that Mr. Joseph Watson was elected Mining Recorder. Mr. Hickox brought with him specimens of rock taken from a ledge in which he is interested which assay from \$200 to \$600 in silver and which have not yet been tested for gold. He will return immediately, and the first shipment of ore from that district will probably be made inside of a week.

From Pinto district, hordinger on the Silver Belt, the most favorable reports are also received, and the development being prosecuted at present is said to be highly satisfactory to the owners of the properties. A boom may reasonably be expected in this section during the coming summer.—*Silver Reef Miner.*

CHLORIDING.—Chloriding is being prosecuted vigorously in different parts of the camp, particularly on the River reefs. Flattering reports come to us from the lessees on the Duffin, Toquerville and Giffried mines. Coffman & Rusk, Miller & Co., Westover & Co. and others on the Duffin have paying leases, and McGavin & Martin on the Toquerville and Burnett & Smith on the Giffried are reported to be taking out high grade ore.—*Silver Reef Miner.*

## Wood River.

From a letter in the Idaho Statesman, we take the following items: Hailey, this rival of Leadville, is beginning to loom up; 20 houses being in process of construction, and \$6 lots sold, with the proviso that buildings shall be erected on them within 60 days. This location is the best on Wood river for a town; being at the mouth of Croy gulch, in which are located the only developed mines, except the Falk, Wolters & Chase property, of the Lower Wood River country. The site is on the upland about one-fourth of a mile from the river, five miles from Bellevue and 12 from Ketchum. Its advantages are: central location, easy of access, available smelter sites, good water, and a reasonable show to get good title to the property bought. Already, one jobbing general merchandising, one drug, two hardware, four general merchandising and one clothing store have goods on the way, and will be ready for business within 40 days; two 25-cent saloons are in full blast, and one four-hit restaurant.

Hailey is the terminus of the Blackfoot & Wood River Stage line, and the Goose Creek & Wood River branch of the Kelton and The Dalles line. The Kelton (Goose Creek) route, is the best for persons coming here via the Central and Union Pacific railroads, being a much better road and as short as the Blackfoot route. From Boise City and eastern Oregon, for people coming by their own conveyance, take the route up the Malad river, which leaves the Overland road near Salmon Falls, on Snake river, and strikes the Goose Creek stage road at the Cottonwoods on Wood river 30 miles from Hailey.

## Smelters.

Only one smelter is located as yet, that of Mr. D. Falk, of Boise City. Mr. Falk stated yesterday that it would be in operation by the middle of May. It is being erected on Indian creek, two miles above Hailey.

## Croy Gulch Mines.

The Bullion, May Flower and Idahoan are all taking out ore, having nearly 200 men employed, and more good miners wanted; the bullion company having advertised at this place and at Bellevue this week for 40 miners. The practical miners now in this section prefer to take their chances prospecting rather than \$4 a day in the mines.

## Rich Strike.

One of the big discoveries since my arrival in the country, is that made by Mr. Owen Riley in Croy gulch last Monday. It shows eight feet of \$100 galena on the face of the ledge, and is said to give good promise of being one of the big mines of this section. This property is located about half a mile from Mr. Croy's ranch, three miles from here. Other good locations are being made every day.

## Building Material.

Boise lumber and saw-mill men could make a big thing by rushing into this country a million feet of building material, there being nothing here except cottonwood logs; not a bundle of shingles, nor a foot of lumber on the river. There is a saw-mill at Ketchum, but it is a rattle-trap affair, and not working.

## Grain and Hay.

Teamsters say it is almost impossible to get a sack of barley in any place on the river, and hay is selling at \$45 a ton, and little to be had at that.

## A New Quartz Mill.

Mr. M. F. Lockwood, of Centerville, Boise county, informs us that he has invented and secured a patent for a quartz mill that will be of great advantage to miners. It is a one-stamp mill built in parts or sections, so that it can be carried on pack mules over mountains where there are no roads, and no other means of conveyance. Mr. Lockwood claims that there are many miners in this and in other Territories who are not able to work mines which they have discovered, on account of the great expense in building roads and erecting mills of the old style. He claims to have overcome this difficulty by constructing a mill that can be put up in any place and at a small expense. He has so much confidence in the success of his mill that he offers to put it up on the installment plan, all ready to run, for those who wish to purchase. He sends the following description of his mill:

1st. The stem weighs 850 pounds, and runs 250 drops per minute, and revolves when the shoe and die come together, which causes it to grind as well as to crush. The motor has three discharges, and is made in sections, so as to be taken to pieces and packed on animals where there are no roads. The stem is the heaviest piece, but when naked weighs 600 lbs. and can be packed on two animals. The cam is so constructed as to operate the stem both up and down; by forcing it downward it makes it strike a blow twice the height of the stem. The drop is six inches, and only requires a five-horse power to turn it. It has a self-feeder, and will crush from 8 to 12 tons ordinary ore in 24 hours. Mr. Lockwood will also furnish a water wheel power, small and simple, that can be run by a common hydraulic, carrying 50 inches of water, with a 60 or 70 ft. pressure. Mr. Lockwood claims that his mill is a great improvement over any mill that has ever been built, both in a saving of expense and in its execution of good work. Persons who desire to purchase or want more full information, can address Mr. M. F. Lockwood, at Centerville, Boise county, Idaho. —Idaho Statesman.

## USEFUL INFORMATION.

**SALTING MEAT.**—Salted meat is far less nourishing than fresh, and far less wholesome. We will endeavor to explain why. The preservation of meat by means of salt has been practiced from time immemorial, and is one of the simplest methods for this purpose. It depends for its efficiency upon the desiccation or drying of the tissues, as the salt used for this purpose enters slowly into solution, deriving the moisture it requires for this purpose from the fluids of the flesh. Hence it is that when dry salt is strewn upon fresh lean meat, it gradually disappears in the form of a liquid brine. As the flesh loses its natural juice, the fibers contract and the meat lessens in bulk. The action of the salt, if a large quantity is applied, penetrates deeply, and as much as one-third of the natural juice of the meat is often forced out of it. The preservation of meat by means of salt, therefore, may be explained to depend upon the separation of water, upon the exclusion of air, and upon the saturation with salt of the juices remaining in the meat. But meat, though preserved in this manner against putrefaction, suffers a notable loss of its normal nutritive properties, inasmuch as the brine which gradually forms about it, contains probably one-third or one-half of the nutritive substances (albumen, kreatin, phosphoric acid, potash, etc.) of the flesh, which are extracted along with the juices. These are the very substances which are more completely extracted by digestion with water, as in making beef tea or broth; and in proportion as these constituents are extracted, they diminish the nutritive properties of the meat. The change in the constitution of the meat by salting has been shown by Leibig to be greater than that produced by cooking, and the loss of nutritive value considerably greater; for in cooking, the nutritive albumen, etc., is simply coagulated in the fibers and retained, while in salting, the extracted substances enter the brine and are lost. Not only does salting greatly diminish the nutritive value of meat, but those who are compelled to subsist upon it almost exclusively for any length of time, are generally afflicted with scurvy, a fact which proves its unwholesomeness, and which doubtless stands in close relation with the loss of the nutritive elements, as vegetable substances which are capable of supplying what the meat has lost, are found to be the best preventative of, and the best remedy against, the disease. —Manufacturer and Builder.

**CLEANSING ZINC, TIN AND LEAD.**—Zinc is cleansed by dipping for a few moments only (as the alkali quickly attacks the metal) in the hot potash-lye, rinsing and dipping into water containing about 10% of sulphuric acid for a few minutes. Rinse in plenty of hot water, and, if necessary, scour with pumice stone powder and a stiff brush, moistened with a weak cyanide solution or scratch brush. The last operation is especially useful when parts have been united with tin solder. Tin, lead, and the alloys of these metals are more difficult to cleanse perfectly than zinc or iron. Scour rapidly with the hot potash and brush, rinse quickly and brush, or dress with a piece of soft clean wood. It is very difficult to obtain a satisfactory deposit of gold or silver directly upon these metals or their alloys. The results are much better if a coating of pure copper is interposed.

**LIQUID WOOD.**—We are informed, says the Northwestern Lumberman, that sawdust can be converted into "liquid wood" and afterward into a flexible and almost indestructible mass, which, when incorporated with animal matter, rolled and dried, can be used for the most delicate impressions, as well as for the formation of solid and durable articles. To accomplish this, the method pursued is to immerse the dust of any kind of wood in diluted sulphuric acid sufficiently strong to affect the fibers for some days, the finer parts being passed through a sieve, well stirred, and allowed to settle. The liquid is drained from the sediment and the latter mixed with a proportionate quantity of animal matter, similar to that used for glue; the mass is then rolled, packed in molds and allowed to dry.

**PARAFFIN** as a preservative of wood has lately been highly recommended, especially with the view of preserving it against the destructive influences of dampness, acids and alkalis. For this purpose, it is suggested to immerse the well-dried wood in a solution of the paraffin in petroleum ether (benzene) or carbon disulphide. The wood absorbs a large quantity of the material, and the evaporation of the solvent leaves the paraffin behind in the pores of the wood. In employing this recipe, care should be taken to guard against the possibility of the ignition or explosion of the materials. A good preventive of combustion would be a thorough coating with a silicate paint.

**ASHES AS EMERY.**—A manufacturer whose business requires the use of large amounts of emery, has been trying an experiment with the ashes of anthracite coal, and he affirms that he has obtained good results from the use of ashes as a substitute for the finer grade of emery. He takes ashes and saturates them with water, the liquid being poured off after standing an hour or two, then being poured off again, and so until he obtains several grades, down to a substitute for emery flour. When dried, the deposit cuts readily and leaves a satisfactory surface.

**PREPARING FLOOR FOR DANCING.**—If planed well, paper the floor with sand paper, then wax it with beeswax and turpentine. To prepare it, melt in an iron pot two or three pounds of common yellow wax; when melted, take the pot of the fire and allow the wax to cool a little, then add one pint of turpentine for each pound of wax, well mix and wash the boards with the mixture, using a large paint brush; the wax must now be well worked in the boards by friction. The surplus wax may be wiped off with a stiff cloth; beeswax and turpentine, with friction, is the best plan extant; in fact, at the present day is still in vogue in many of the chateaux in the south of France.

**A NEW ART PROCESS.**—A curious device, whereby pictures of various kinds are burnt out on a piece of ordinary-looking rose-colored paper, has been brought out by a Berlin merchant, Herr Bergel. You apply a glowing match at two finely perforated points, and the sparks communicated then begin gradually to move over the paper, working out the picture. Neither leaves its proper path, nor injures the paper beyond, and when the end of the path is reached, the spark goes out. A negative and positive are thus obtained, after the manner of silhouettes. The contrivance proves highly entertaining, and may be employed for educational purposes.

**CEMENT FOR RUBBER.**—Powdered shellac is softened in ten times its weight of strong water of ammonia, whereby a transparent mass is obtained, which becomes fluid after keeping some little time without the use of hot water. In three or four weeks the mixture is perfectly liquid, and when applied it will be found to soften the rubber. As soon as the ammonia evaporates the rubber hardens again—it is said quite firmly—and thus becomes impervious both to gases and to liquids. For cementing sheet rubber, or rubber material in any shape, to metal, glass and other smooth surfaces, the cement is highly recommended.

**GROWTH OF TREES.**—As the result of observations, and from the testimony of reliable men, the following is about the average growth in 12 years of the leading desirable varieties of hard wood when planted in belts or groves and cultivated: White maple, 1 foot in diameter and 30 ft. high; ash, leaf maple or hox elder, 1 foot in diameter and 20 ft. high; white willow, 1 1/2 ft. in diameter and 40 ft. high; yellow willow, 1 1/2 ft. in diameter and 35 ft. high; Lomhardy poplar, 10 inches in diameter and 40 ft. high; blue and white ash, 10 inches in diameter and 25 ft. high; black walnut and butternut, 10 inches in diameter and 20 ft. high.

## GOOD HEALTH.

## Sneezing.

"God bless you!" is the common expression of Europeans when you sneeze in their presence; sneezing having been considered in ancient times the result of a demoniac possession, to avert the evil influence they invoke a blessing. But the true philosophy of a sneeze is set forth in an article in the Popular Science Monthly for April under the heading "What is a Cold?" The whole of it is worth reading, but we have only room to transcribe what relates to sneezing.

"Sneezing in catarrh is a method nature adopts to stimulate the prostrate nervous center, and thus enable it to reassert its proper control over the blood supply to the part; indeed, it will be found that the effects of being exposed to a draught of cold air are often completely destroyed by a succession of sneezes. Of course, nature does not always immediately succeed in these efforts; but, when she does not, the shock from which the nervous center suffers gradually passes away, and the blood-vessels again come under the control of the little nerves which regulate their caliber, and so the catarrh disappears in a few hours, or at most in a few days. It sometimes happens that the shock from the cold air acting upon the nervous center is of such severity that the consequent inflammation is intense enough to check the secretion of mucus altogether, and in consequence the mucous membrane is dry as well as inflamed, and the suffering very much intensified."

**FEAR ON DISEASE.**—It is said that while the plague was raging in Buenos Ayres the grave-diggers here charmed lives. Of the 300 men so employed, not one died of the disease. It has often been noticed that during the prevalence of pestilential diseases physicians, undertakers, nurses and grave-diggers, whose business compelled constant liability to infection, have usually escaped in a far greater ratio than their numbers would warrant. The "charm" of this immunity from the prevailing scourge is very simple. They are not scared. They are positive to the disease, and repel its attacks. Fear is a great ally of death. Whoever is afraid of disease is in a negative condition, and really invites its approach. And thus it is the world over. The brave die but once, while cowards die many times. Much unnecessary alarm exists in every community in regard to many diseases. We are, it is true, all liable to sickness and death. But if we are all sober, cleanly and brave of heart, we need have no fear of disease of body or mind.

**TOBACCO DISEASE.**—A writer in Boyce's Anvil testifies as follows respecting tobacco as a cause of disease: "For eleven years my right hand was sorely afflicted with a most loathsome disease. Its first appearance was shortly after my debut as a telegraph operator, and consisted of four or five very small, watery pimples. They increased in number, however, till they could hardly be counted, and each day became more and more troublesome. Instead of a thin, watery fluid, they now began to exude a thick, offensive matter, and the physicians called it an aggravated case of salt rheum. My hand and wrist became one mass of sores and scabs. I spent some \$300 doctoring with physicians and patent medicines, yet nothing seemed to give much relief; but in three months after tobacco was stopped, the disease began to disappear, and to-day there is not a particle of it to be seen about me."

**A NEW PORK PARASITE.**—A Berlin microscopist has recently discovered a new parasite in pork, which is described as "a small leech-like worm," which has not been heretofore known. The worms are found crawling about among the muscular fibers, sometimes moving very actively. A German microscopical journal of recent date contains a full description of the worms with illustrations. Notwithstanding, pork and beans still holds its place as a standard article of diet among the masses, and ham and sausage are in as great demand as ever. It is evident that the pork-loving world have become reconciled to a "diet of worms." We prefer to eschew the scavenger; let those who will, chew him.

**EARACHE.**—A remedy for this dreadful torture is recommended by a correspondent of the London Lancet, as follows: "In the course of practice you will often be called upon to attend a case of earache. This means, pathologically speaking, acute inflammation of the membrana tympani. Now, in such a case you may quickly subdue the inflammation, relieve the patient from the excruciating pain he is suffering, and save him, perhaps, from subsequent confirmed deafness. The treatment from which such a very desirable result may be obtained is similar to that which you will find so beneficial in analogous cases of eye disease; viz.: leeches behind the ear, hydrarg. c. creta and belladonna powders, with warm fomentations."

In searching for a vegetable remedy, Dr. L. D. Buckley suggests, in the New York Medical Journal, the gelsemium, the yellow (false) jessamine, the heartful climbing evergreen which produces the large, very fragrant yellow flowers, from the relief it affords as a nervous sedative to the skin, might be useful. He has experimented with it very successfully, and after prescribing it for two or three years, mainly on adults suffering from eczema, he feels prepared to advise it as a means for the relief of itching in certain cases. He has used the tincture of the drug only, giving it in 10-drop doses to begin with, and, when no relief was obtained, repeating the remedy in 12 or 15-drop doses at intervals of half an hour, until results were obtained or until a dram or so had been taken in two hours.

**TREATMENT FOR A FELON.**—Take of soft lye soap and flaxseed-meal, or corn-meal, a sufficient quantity, stirring the meal in slowly and thoroughly, so as to form a salve or poultice. Envelope the finger in this, applying snugly, to bring it in close contact. Renew the poultice every 12 to 24 hours. Don't try every prescription you may hear of. Depend on this. It will, if applied in time, absorb the disease; if adopted later, it will bring it to a small "head" (if too far advanced to be "scattered," when it may be picked almost painlessly. —Therapeutic Gazette.

**NEW REMEDY FOR PARASITES.**—Physicians are often troubled to give relief to the symptom of itching which so frequently forms a prominent feature in certain skin diseases, and the most varied local measures are often used with the result of aggravating the local irritation. The list of internal remedies used for allaying this distressing condition is a limited one, and from it chloral and bromide of potassium stand out almost alone; but the objections to the continued use of these are too obvious to require mention.

**THE CAT AS A PEST DISTRIBUTOR.**—The domestic cat is again charged with spreading disease, this time by the physicians of a district in Sullivan county, this State, where small-pox is epidemic. In several cases the proof is pretty strong that house cats carried the pest, and owners of cats have been warned to keep them from roaming about. —Exchange.

**A BEAUTIFUL COMPLIMENT TO THE PHYSICIAN.**—I dare not place any gift, however beautiful, or any success, however brilliant, above the talent or the skill which can relieve a single pang, and the self-devotion which lays them at the feet of the humblest fellow creature. —Oliver Wendell Holmes.

**THE LEMON VERBENA.**—The well-known lemon verbena is systematically gathered in Spain, where it is regarded as a fine stomachic and cordial, used in the form of a decoction. It is said that if it be used one need never suffer from flutulence, nervousness, diarrhoea or loss of appetite.

## TABLE OF CONTENTS.

**GENERAL EDITORIALS.**—A Novel Planing Machine; The State Engineer; Montana Placer Mines; Academy of Sciences, 289. Passing Events; Marine Dredging; Garibaldi South Mine; Brake for Hoisting Engines; The Mining Bureau Appropriation; The World's Fair, 295. Mount Shasta; Cleaning Drill Holes; High Explosives, 297-300. Notices of Recent Patents, 300. **ILLUSTRATIONS.**—Compound Planing and Shaping Machine, 289. Pneumatic Drill-Hole Cleaner; Mt. Shasta, 297. **CORRESPONDENCE.**—Stirring Roasting Ores, 290. **MECHANICAL PROGRESS.**—A New Silver Steel; More Daylight; Railroad System of Mexico; Influence of Hardness on Magnetized Steel; New Use for Copper, 291. **SCIENTIFIC PROGRESS.**—The Future Life; A New Method; New Conclusions; Pictures by Telegraph; Egyptian Antiquities—Important Discovery; Purification of Expended Lubricating Oil; Submarine Photography; Heads Diminishing; Saxifrage, 291. **MINING STOCK MARKET.**—Sales at the San Francisco Stock Boards; Notices of Assessments, Meetings and Dividends, 292. **MINING SUMMARY** from the various counties of California, Nevada, Arizona, Idaho, Montana, New Mexico, Oregon, and Utah, 292-93. **USEFUL INFORMATION.**—Salting Meat; Cleansing Zinc, Tin and Lead; Liquid Wood; Ashes as Emery; Preparing Floor for Dancing; A New Art Process; Cement for Rubber; Growth of Trees, 295. **GOOD HEALTH.**—Sneezing; Fear of Disease; Tobacco Disease; A New Fork Parasite; Earache; Treatment for a Felon; New Remedy for Parasites; The Cat as a Pest Distributor; A Beautiful Compliment to the Physician; The Lemon Verbena, 295. **MISCELLANEOUS.**—Climate of Tehama County; Copper Smelting—Its History and Processes—No. 4; Safety for Miners; A New Gravel Mining Enterprise, 290. The Miner's Soliloquy (poetry); Annual Expenditures on Claims; Volatilization of Gold; Alter, Mexico; Nitrate of Soda; Stockholders' Rights; Swelling the List of Preserved Products; Mining on Snake River; Silver Belt, 294. Wood River; A New Quartz Mill, 295.

## Business Announcements.

Water Wheel—L. A. Peltou, Camptownville, Yuba Co., Cal. New Mining Fields—J. A. Campbell & Co., Evanston, Wyo. Distillery for Sale—Geo. Johnston, S. F. Dividend Notice—Standard Coal, M. Co. Hoisting Works—Rankin, Brayton & Co., S. F. Deputy U. S. Mineral Surveyor—Thos. W. Reese, Oroville.

## Passing Events.

In looking over the exchanges of the week, the editor of this journal was very much impressed with the numerous "strikes" which are occurring in California. All over the State comes news of progress and advancement. Old mines are being opened. New mines are being found. But most important of all is the renewed proof that an economical era has set in, and that legitimate mining is being carried on as it should be, at the same expense, proportionately, as any other business. The good bullion producing mines of the State are being worked quietly and without any notoriety or fuss, but they are none the less prosperous for this.

Arizona, Wood River and Alaska are still attracting attention, particularly the Idaho district. Hundreds of men are going in there. A gentleman who visited the region not long since, tells us that there are some 2,000 claims in that part of the country already taken up.

Arizona is still attracting large numbers of men, and is producing bullion in a better proportion than it was last year.

New Mexico is scarcely prospected enough to say very much about yet. Bad reports come mixed with good ones. Some people write disparagingly of New Mexico, Wood River, Arizona and Alaska, but it probably depends very much on a man's luck what reports he sends back about any new region.

A CATHOLIC Congress will be held in Madrid in October, which will be attended by Catholic notabilities from every part of the world.

## Marine Dredging.

Dr. Gustav Eisen wrote some time since to Professor Davidson, President of the California Academy of Sciences, stating that he wished to sell the outfit for collections, which he had brought from Stockholm, in the expectation of being able to make dredgings along our coast.

Prof. Davidson at once called upon Mr. Gerstle, of the Alaska Commercial Co., and stated the case to him, and asked that he and his associates would purchase the outfit and present it to the California Academy of Sciences. This he agreed to do upon the condition that Prof. Davidson should personally examine the articles of the outfit, and decide upon the fairness of the price named. With Mr. Harford, the director of the Museum, he performed that duty, and, upon reporting to Mr. Gerstle, the money was immediately paid and forwarded to Dr. Eisen.

The outfit is very complete, and embraces dredges, trawls, large copper tanks for holding large and numerous specimens, with the larger tank full of alcohol; boxes with large numbers of specimen bottles of various sizes, tins for holding material for exchanges, soldering tools, etc., etc.

Most of this material comes very opportunely into immediate use in the work of the Academy. It is hoped that the dredging apparatus will also come into use before long. Neither our coast or bay has been dredged for specimens, which seems strange when we remember that the field is a fresh one. There is a good deal of room for scientific work all along the coast, and especially is it desirable that a scientific school of zoology should be instituted at some such locality as Monterey bay. That at Naples, visited by the President of the Academy in 1875, has become not only a model of its class, but has drawn to it students and investigators from all parts of Europe. Agassiz established the school at Penikese, but it failed at his death. John Hopkins' University is promoting the study at Baltimore, and the U. S. Coast and Geodetic Survey is studying the development and natural history of the oyster at Chesapeake bay. A number of small schools have been established along the Atlantic coast, where people go for a few weeks or more in summer and study natural history.

The Alaska Commercial Company, which presented the articles before referred to, to the Academy, deserve recognition for their services to science. They have interested themselves in collecting on the northern coasts, specimens of such character as they supposed would be of value here. Some magnificent specimens of the fur seal, male, female and young, were given by them to the Academy. Also numerous specimens of Alent implements and clothe. At their building they have a collection relating to the archaeology and zoology of Alaska, systematized by Captain Niebaum. This has been classified by one of our fellow-members, and it is understood will be presented to our Academy at no far distant day.

## Garibaldi South Mine.

The Garibaldi South mine, situated in Calaveras county, 10 miles above Copperopolis, has been opened by a tunnel 150 ft. long, crossing the vein at right angles; and a drift on the vein 80 ft. has been run, showing the vein to be 15 ft. wide, trending north 47° west, and dipping 45° north, lying between diorite on the foot and auriferous elate on the hanging wall. The average of the ore in free gold is from \$7 to \$9 per ton, with 2% to 3% of sulphurets, assaying from \$200 to \$250 per ton. Ore has been found in this mine assaying free gold over \$5,000 per ton, but the average ore is about \$10 per ton.

There are over 10,000 tons of ore above the drift ready to be stoped down. A water power sufficient to run 80 stamps belongs to the property, the water being free. There are 40 acres of land, a fine mill site, timber in abundance, lumber at \$25 per thousand, which, with other benefits, makes it possible to mine and mill at \$2.50 per ton.

The "auriferous slates" above the hanging walls are valued at \$12 to \$15 per ton. They are from 5% to 10% sulphurets, assaying from \$143 upwards per ton. The width of these slates is not known beyond 10 ft., as the crosscut has not shown the barren or country rock. Enough is known to warrant the erection of a 40-stamp mill.

**EXTINGUISHING FIRES IN MINES.**—At a recent meeting of the Engineers Club, Philadelphia, Dr. H. M. Chance described an attempt to extinguish the Kehley Run Colliery fire at Shenandoah City, by carbonic acid gas and nitrogen. The gas was generated in an open brick furnace with reversed draught, and forced into the mine through four 3-inch pipes by injectors supplied with steam at 60 lb. pressure. Each pipe was exposed to supply 1,500 cubic ft. per minute, or a total of 6,000 cubic ft. per minute. The attempt was entirely unsuccessful, and Dr. Chance attributes its failure principally to the impossibility of making the mine airtight, but also considers that the gas was delivered at too high a temperature, and that it was possibly mixed with carbonic oxide.

## Brake for Hoisting Engines.

Engene O'Neill, the accomplished chief draftsman of the Union Iron Works, in this city, is not only an expert at putting into proper shape the ideas and plans of others, but is an inventor or originator himself. He has perfected several different inventions, the best known of which probably is his cut-off motion and valve gear, which has been applied to so many of the big engines on the Comstock. His attention having been turned largely to mining machinery, it is natural that he should be bent upon improvements in that direction. He has just patented through the MINING AND SCIENTIFIC PRESS Patent Agency an improved hoisting machine brake, which is more particularly applicable to heavy mining machinery.

This invention consists in a novel means for suspending the brake blocks and shoes upon opposite sides of the wheel or pulley upon which they act, so that while swinging about their center of suspension, they act in radial lines toward the center of the wheel. It further consists in an adjustment by which the movement of the two opposing brakes, operated from opposite sides of the wheel by a single mechanism, may be regulated in their movements to and from the wheel.

The brake shoes are secured within the brake blocks in the usual way. These brake blocks have boxes at the rear, midway between the ends, through which pins pass horizontally and have their ends supported in the upper ends of links, so that the brake blocks may turn upon the pins and adjust themselves and the shoes to the face of the wheel when pressure is brought upon them. The lower ends of the links are supported on fulcrums, about which they move when the brakes are moved to or from the wheel. The brakes are supported so that their centers are below the center of the wheel, and the links incline outward from the wheel, so that when released, the brakes will fall away from the wheel by gravitation. The brakes are operated simultaneously by a T-headed lever, this lever being connected with an operating lever by a link, or actuated in any suitable way.

One of the arms of the T-head is connected with the center pin at the rear of the brake block upon the inner side with the lever, and the other is connected with the pin of the opposite brake block by connecting or side rods.

When the long arm of the lever is moved upward, one of the transverse arms will force its brake block against the wheel from that side, and the other one will, through its side rods, draw the opposite block against the wheel from the other side. The blocks move about the pivots of their supporting links in radial lines towards the center of the wheel, and by reason of being joined upon the pins at their center they will press evenly against the rim of the wheel. The weight of the brake block and the inclined position of their supporting links, will cause the blocks to fall away from the wheel, as soon as the pressure upon the lever is relieved.

To regulate their movement and make them fall back evenly and to an equal distance, Mr. O'Neill employs adjusting screws, which pass through nuts supported upon the stationary floor above the center of support of the brake blocks, and other screws which pass through a cross bar which extends between the links. Suitable plates or boppers upon the backs of the brake blocks strike against these screws, and the movement of the brakes is thus limited and the upper and lower portion move back equally.

**HYDRAULIC WELL-SINKING DEVICE.**—The assertion that "there is nothing new under the sun," is often discussed, but there is one thing sure at all events: Solomon never sank for artesian wells in the manner it is done now. One of the most novel and complete inventions to which attention has been turned of late is what might be termed a "hydraulic well-sinking machine," invented by George Vincent, Esq., of Stockton, and designed by Mr. C. V. B. Downing, M. E., of this city (patented through the MINING AND SCIENTIFIC PRESS Patent Agency). This device has been tried at Stockton lately, and we are told, with assured success. It is simply a hydraulic jack on stilts, for forcing one length of pipe after another into the ground until flowing water has been struck. For a new combination of old ideas to accomplish the purpose designed, and for a first trial, it has satisfied the originators perfectly. We are told it will send a 9-ft. length of pipe into the ground in half a minute, and that it readily crushed through a stratum of hard pan 8 inches thick. They hope to revolutionize the well business, and to supersede the old process of boring. We hope to be able to present our readers with a full description of the machine and its workings, accompanied by a cut, in some future issue.

We notice by an exchange, published in an adjoining county to this, that "croppings of petroleum are found to be so numerous and copious on the eastern side of the Summit from Drhams to Santa Cruz line, that, as this latter commodity is believed to flow only from coal beds, little doubt exists that prospecting for coal will ere long receive an impetus."

## The World's Fair.

The New York people who are throwing stumbling blocks in the way of the proposed World's fair, ought to remember that no exhibitions of the kind ever fail to be profitable. This is true either with international exhibitions or local fairs. All such enterprises pay very well. And they not only pay the projectors, but they pay the town in which they are held.

A little foolish matter about exact location ought not to break up the whole matter. Nor should any petty jealousy serve to block the wheels. Every one believes New York is the place to hold the exhibition, and the New Yorkers ought to be complimented at the selection. At all events, they ought to help the affair along in its inception, when it needs help. After it is once started it will work out its own salvation, and will very materially assist the city in which it is located.

California did not make much of a show at the Centennial exhibition, and some of the other States also failed to see the importance of that event till it was all over. They now see the mistake they made in not being well represented. They are anxious to come to the front at the next World's fair. Thousands of people who stayed at home before will go this time, knowing what an educator and instructor such an exhibition is.

We only hear on these the echoes of the grumbles and dissensions about the site, etc., which are taking place. But we do not want to hear even that. We want to hear that a peaceful solution of all the differences has been found, and that New York will graciously accede to the demands of the nation and not hold back like a spoiled child any longer. New Yorkers, though prosperous, can afford to be more so; and, being well to do, ought to desire to see what other places are doing. With an exhibition of the products of the United States gathered at one spot, now, the Centennial would be excelled. All the Pacific coast States and Territories would join with a will this time and would show the older communities what advancement they are making. Let us have this World's fair by all means.

## The Mining Bureau Appropriation.

We have already mentioned the fact that the Senate refused to concur with the Assembly in appropriating \$12,000 for two years to the State Mining Bureau. The bill was amended by the Senate striking out the appropriation altogether, thus leaving the Bureau with the small income only it derives from the taxes on mining stocks. Last week in the Assembly, consideration of the Senate amendment striking out the \$12,000 appropriation came up. McClure took the floor and vigorously and vehemently opposed the appropriation, to the surprise of all who had heard him at the regular session earnestly favor the giving of \$10,000 per annum to the Bureau, and also to have 1,000 extra copies of the State Mineralogist's report printed.

Wasson, of Mono, again took the floor and said with an animation which hushed the House into silence and attracted the attention of all: Will the gentleman from San Francisco (McClure) please explain to the House his consistency in now opposing the appropriation of \$6,000 per annum to the support of the Mining Bureau, when he at the regular session of this Legislature favored the giving to that same Bureau the sum of \$10,000 per annum. The support of this appropriation for the Bureau, said he, is recommended by the Governor in his annual message, and the Executive, in calling the extra session, implied, so far as words could possibly do, that this was a State institution, as much as is the State University, the insane asylums, etc. Then he vigorously urged a call of the roll, and amid much applause sat down. The House refused to concur in the amendment of the Senate to strike out the appropriation, by a vote of 47 yeas to 13 nays.

As the matter now remains, as we understand it, the question will be left to the Committee of Conference. It is probable that whatever is agreed upon by this committee will be carried out by both Houses of the Legislature. Mr. Wasson has made a good fight on this question, for which he deserves the thanks of the mining community. He has also been a strong advocate of continuing the State Engineer in office, at least until all the maps, etc., are finished.

**RICHMANN DRILLS.**—The Richmann Drill and Air Compressor Co., in this city, are making quite a number of their machines. One of the compressors is a very large one, with 16-inch bore and 20-inch stroke. They are also making a duplex—one with two cylinders—which is to be run by water power, on a California mine. The drill and compressor at the Barbee & Walker mine, Silver Reef, Utah, is working first-rate. There is one compressor and two drills at the Yuba mine, Nevada county; one at the Central Arizona mine, Arizona; one at the Florida mine, Calaveras county; and one at Silver Hill mine, on the Comstock. All of these are said to be giving good satisfaction. A compressor and two drills were shipped this week to a mine near Oroville, Butte county.

Mount Shasta.

The engraving on this page shows Mt. Shasta from a point of view different from that held by most who look upon it.

The noblest mountain in the United States is Shasta. It is said that Whitney is higher, but Whitney has for its base the Sierra Nevada, and the peaks around it dwarf its own tremendous height. But Shasta rises from the plain a single mountain, and while all the year around the lambs gambol at its base, its crown is the eternal snow. In the hot summer days, as the farmers at Shasta's base gather their crops, they can see where the wild wind heaps the snow drifts about his crest. The mountain is one of winter's stations, and from his forts of snow upon its top he never withdraws his garrison. There are the bastions of ice, the frosty towers; there his old hugler, the wind, is daily sounding the advance and the retreat of the storm. The mountain holds all latitudes and all seasons at the same time in its grasp. Flowers bloom at its base, further up the forest trees wave their ample arms; further still the brown of autumn is upon the mountain slopes, and over all hangs the eternal winter. Standing close to the mountain's base, the human eye and mind fails to grasp the immensity of the mountain. But as one from a distance looks back upon it, he discovers how magnificent is the sight. For days will the mountain fold the mist about its crest like a veil, and remain hidden from mortal sight, and then suddenly, as if in deference to a rising or setting sun, will roll back the vapors, and the watcher in the valley below will behold gems of topaz and of ruby made of sunbeams set in the diadem of white, and toward the sentinel mountain from a hundred miles around men will turn their eyes in admiration. Thus it frowns and smiles alternately through the years; it heils the incoming and outgoing centuries, changeless amid the mutations of ages; forever anster, forever cold and pure. Of all American mountains it has the most sovereign look; it leans on no other height; it associates

Cleaning Drill Holes.

J. L. Prentiss, of Canyon City, Colorado, has devised a means by which drillings may be easily and quickly removed from drill holes,

Pneumatic Drill-Hole Cleaner.

and which is simple in construction and convenient in use. A good many miners will find this a useful device, especially in certain kinds

In the lower end of the tube *F* is placed a ball valve, as shown in the drawing. The tube *F* is made of less diameter than the hole to be cleaned, and its lower edge is notched to allow the drillings to enter the tube readily.

In using the instrument the metal tube *F* is lowered into the drill hole until its lower end rests upon and is embedded in the drillings. The bulb *A* is then compressed, forcing the air out through the hole in the connection piece *B*. The hole is then closed with a finger, and the bulb *A* is released and allowed to expand, and the atmospheric pressure will force the drilling into the lower end of the tube *F*, to take the place of the air which passes up into the bulb *A* when the pressure upon the bulb is removed. By compressing the bulb *A* two or three times, all the drillings will be forced from the drill hole into the tube *F*, and the device may then be removed from the drill hole. The ball valve at the lower end of the tube is forced up with a finger and the drillings allowed to flow out. If desired the rubber bulb may be replaced by a bellows suitably formed to produce a vacuum.

High Explosives.

(Written expressly for the MINING AND SCIENTIFIC PRESS, by M. EISELES.)  
Number Five.

Dynamite or Giant Powder.

No better illustration can be given of this material than by repeating Alfred Nobel's, the inventor's, own descriptive words, which are as follows:

"My invention relates to a new and useful combination or mixture of nitro-glycerine with some absorbent substance, whereby the condition of the nitro-glycerine is so modified as to render the resulting explosive compound more practically useful and effective as an explosive, and far more safe and convenient for handling, storage and transportation than nitro-glycerine in its ordinary condition as a liquid. The invention consists in combining or mixing

or absorbent substance with which it is mixed, and then assuming the altered form of a powder or paste remains in the bore hole in which it is placed, without leaking through the seams of the rock. Another advantage over liquid nitro-glycerine is, that this mixture can be made to fill the bore hole more closely than a cartridge case will, owing to the irregularities of the shape of the hole, which greatly increases its efficiency. The liability of fluid nitro-glycerine to accidental explosion from agitation or concussion renders its handling and transportation very dangerous. This danger is, however, almost entirely obviated by the use of the compound, because, when mixed with a suitable absorbent the nitro-glycerine is far less sensitive to shocks than when in a liquid condition, so it may be handled in mass either loose or in packages with impunity. This invention then, consists in mixing liquid nitro-glycerine with some solid substance, which will absorb and retain a sufficient amount of nitro-glycerine to form an efficient explosive. The substance which is believed to be the best adapted for this purpose is a kind of silicious earth found in various parts of the globe, and known by the various names of silicious marl, tripoli, rotten stone, kieselguhr. The peculiar variety of this material best suited for this use is homogeneous, has a low specific gravity and great absorbent capacity, and is generally composed of the remains of infusoria. So great is the absorbent capacity of this infusorial earth, that, when in a pulverized condition, it will take up three times its own weight of liquid nitro-glycerine, and still retain the form of a powder. Other porous substances, even though they have less absorbent capacity may be used, but in this case the explosive strength of the powder will be diminished, owing to the smaller proportion of nitro-glycerine contained therein. Chalk, for example, will absorb about 15% of nitro-glycerine and retain its powdered condition; and porous charcoal, although of greater absorbent capacity, has less elasticity of particles, so that nitro-glycerine is apt to squeeze out of it. Any of the various vegetable or mineral substances susceptible of pulverization or comminution, and which will retain nitro-glycerine by absorption, may be substituted for infusorial earth. The

MT. SHASTA—SUMMIT 14,440 FEET ABOVE THE SEA, AS SEEN FROM THE OREGON AND CALIFORNIA STAGE ROAD.

with no other mountain; it builds its own pedestal in the valley and never doffs its icy crown. The savage, in the long ago, with awe and trembling, strained his eyes to the height, and his clouded imagination pictured it as the throne of a deity, whence issued the snow, the frost and the wild wind from their hewing place on the mountain's top. The white man with equal awe strains his eyes upward to where the sunlight paints with purple and gold the mimic glaciers of the height, and is not much wiser than was the untutored savage in trying to comprehend how and why the mighty mess was upheaved. It is a glory in itself. It seizes the clouds with icy arms and compresses them until their contents are dropped upon the thirsty fields below; from its base the Sacramento starts on its way to the ocean; despite its frowns, it is a merciful agent to mankind, and on the minds of those who see it in all its power and splendor, a picture is painted which will last as long as the gift to admire anything magnificent is left.

of ground, where the drillings are hard to remove.

In the engraving *A* represents a rubber bulb four inches (more or less) in diameter, and with which is connected a short tube or connection piece *B*, provided with a hole in its side for the escape of the air when the bulb *A* is compressed.

In the outer end of the connection piece *B*, or in the coupling *C* that connects the said connection piece *B* with the rubber hose *D*, is placed a valve, *E*, opening upward. The valve *E* prevents the air from being forced into and compressed in the rubber hose *D* and the tube *F* coupled to it, when the bulb *A* is compressed.

The end of the metal tube *F* may be reduced in diameter to receive the rubber hose *D*, or the hose can be connected to said tube by a coupling, in order that the hose may be readily detached and replaced with a longer one or a shorter one, as the depth of the drill hole to be cleaned may require.

with nitro-glycerine some porous or absorbent substance, which, being free from any quality which will cause it to decompose, destroy or injure the nitro-glycerine, forms, in combination with it, an explosive compound possessing certain marked properties of great practical utility, which not only increases its efficiency, but also obviates many of the serious practical objections to the employment of nitro-glycerine as an explosive. Some of these peculiar properties of this mixture will be briefly stated: Nitro-glycerine being a liquid, it is usually necessary in exploding it as an explosive for blasting purposes, to place it in cases or cartridges formed of paper, metal, or other substance, which must, of course, be of somewhat smaller diameter than the bore holes, as, if not so enclosed, the nitro-glycerine would permeate the seams of the rock, and prove highly dangerous to the miner, on account of its liability to explode in subsequent drillings; but by means of my invention, the nitro-glycerine, being held in combination with the porous

relative proportion of the ingredients used in making this non-explosive compound will vary according to the absorbent capacity of the substance mixed with the nitro-glycerine, it being preferable in all cases—and this is the only limit—to use so much only of the liquid nitro-glycerine as the absorbent substances will retain without liability to subsequent separation by compression or leakage. Where the absorbent used in a powdered condition is infusorial earth, a thin paste or semi-fluid condition of the mixture is to be avoided.

"The method of manufacturing this explosive compound with infusorial earth is as follows:

"The earth being thoroughly dried and pulverized, is placed in any suitable vessel, and the nitro-glycerine is then gradually introduced, and thoroughly mixed with the powdered earth, which is effected either by stirring with the naked hand or by means of any suitable wooden instrument, worked either by machinery or by

### MOREY & SPERRY,

MANUFACTURERS OF

Gold and Silver Grinding and Amalgamating Machinery

HOWLAND'S PULVERIZER Takes the Place of the Cumber-  
some Stamp Mill and can be put up in one day ready for work.

IT HAS BEEN FULLY PROVED AND TESTED.

It weighs complete, 7,000 pounds. It costs \$1,500 ready for the belt. Will crush one  
per hour of hard quartz that will pass through a 40-mesh screen. The wear is less  
in the stamp mill. Its wearing parts are plain castings and can be dropped into  
position in a few moments, as shown by the letters A, B and C, no  
bolts or keys are required; it can be set upon the floor of a mill  
with no expense for foundations, and can be used to crush and  
work in charges or continuous. It will amalgamate either gold or  
silver ores, making a simple, cheap and effective mill, it requires  
twelve-horse power.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating  
Pans and Separators for Gold and Silver Ores, Ohio  
Furnaces, Retorts, Rock Drills, Air Com-  
pressors, Steel Shoes and Dies for Stamps, and every  
description of Mine and Mill Snags. Iron Work  
complete for Wood Frames, also

**SPERRY'S  
WROUGHT IRON FRAME  
FOR STAMP MILLS.**

Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to  
put upon the foundation. We construct Mills with Stamps weighing from 550 to 900 pounds for Gold and Silver Ores.  
Wet or Dry Crushing Mortars.

### A Card from Architects.

**The California Architect and  
Building Review.**

Office, No. 240 Montgomery Street, San Francisco, Cal.

It is with pleasure that we publish the following from

prominent Architects in this city.

Believing that a journal of its kind is a necessity on this

coast, and judging from what has appeared in the "Quarter-

ly Architectural Review," we are led to believe that the

CALIFORNIA ARCHITECT AND BUILDING REVIEW

will be worthy of generous support and encouragement. We

therefore pledge our cordial sympathies, personally, and hope

that the enterprise will receive kindly recognition and liberal

support from all Architects and Builders and the public gener-  
ally. (Signed) David Farquharson, Wright & Saunders, S.

## PATENTS AND INVENTIONS.

### List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," U. S. and Foreign Patent Agents.

FOR THE WEEK ENDING APRIL 19, 1881.

240,354.—WHIP—J. W. Allen, Canyon City, Or.  
240,303.—PRESS—L. A. Comins, San Jose, Cal.  
2,879.—HANGING DOORS—C. N. Earl, Los Angeles, Cal.  
(re-issue)

240,242.—BELLOWS—J. Fletcher, S. F.  
240,261.—DRSTROYING PHYLLOXERA—E. H. Lindeman, S. F.  
240,329.—HOISTING MACHINE BRAKE—E. O'Neill, S. F.  
240,330.—LIGHTING JACK—A. H. Parks, Bloomfield, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DREW & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

### Notices of Recent Patents.

Among the patents recently obtained through DREW & CO.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

**BALING PRESS.**—Lucy A. Corning, San Jose, Santa Clara county, California. Patented April 19, 1881. No. 240,303. This invention relates to certain improvements in that class of machines known as horizontal baling presses, and it consists of a horizontal box having four chambers and two feed spaces so arranged that each feed space can be employed to feed two chambers, while two followers or baling heads are united by bars which are attached upon each side of the press by cranks upon the end of a shaft, so that they are moved back and forward in the press box simultaneously, each pressing two hales as they are wound alternately backward and forward. These followers, in their forward motion, press the end of two hales, and in their backward journey, two others. It consists, further, of a belt or clasp, acting with a lever, by which the doors of the press chambers are fastened; and on peculiar crank-wheels which serve to actuate the followers on a frame, and also as stops at the end of the measurement in each direction. The object of this invention is to make one machine do the work of four single ones, with the same motions, and to provide a machine which can be easily operated, and of such simple construction that an ordinary blacksmith and carpenter can build it.

**DITCHING PLOWS.**—Alfonso Haskies, Davieville, Yolo Co., Cal. Patented April 12, 1881. No. 240,127. This ditching plow has a coulter, wheel, made adjustable, and a shoe secured to the standard. The shoe is of considerable length, narrow, and flat upon its bottom, so as to run on the bottom of the trench and smooth and level it like a plane. The point is formed or received on a bar or plate which has its upper end secured to the standard, and extends down to the front of the shoes, thus forming a support to the shares, which may be held to it. The shares conform to the outline of this bar, and are made narrower and flat at their lower front end, so as to receive the earth from the point. This flat surface extends upward and backward, widening slightly up to the point where the shares begin to curve outward. The surface of this portion is nearly on a straight line from the point, and brings the earth up to the flaring portion of the shares, which then take it and throw it outward upon each side and entirely clear of the trench. By this means trenches may be formed of any desired depth, and having a perfectly smooth, flat bottom, suitable for laying cement or other pipe. The plow is specially adapted to the formation of ditches in which irrigating pipe is laid, and which is formed and laid at one operation from the plastic material.

**FLUSHING SEWERS.**—Peter Burke, Virginia, Nev. Dated April 26, 1881. No. 240,655. This invention relates to a novel means of flushing and cleaning sewers and it consists in the employment of a series of water pipes which are suitably supported or hung from the apex of the sewer, and are provided with a series of nozzles standing at such an incline that they will discharge a jet of water into the deposit at the bottom of the sewer irregularly, and in the direction of the flow, so as to loosen up the deposit and cause it to move on through the sewer. These nozzles and supplemental pipe are connected in sections with a main water pipe exterior to the sewer, and have cocks near the curb, so that water may be turned into any one or more sections at one time, and thus flush that part of the sewer. As a considerable portion of the gas generated in sewers is soluble in water, this invention will have the effect of taking up some of this gas and reducing the pressure on the sewer, thus preventing in a great measure the evil effects caused by this pressure, and the escape of gas into buildings which are connected with the sewer.

A PROMINENT diplomatist at St. Petersburg reports that the Czar and his counsellors are disposed to adopt the rigorous oppressive measure, having no example in Russian history.

### High Explosives, etc.

(CONTINUED FROM PAGE 297.)

hand. Where infusorial earth is used, the proportions may be conveniently varied, from 60 parts by weight of liquid nitro-glycerine and 40 parts by weight of infusorial earth; or 78 parts by weight of nitro-glycerine and 22 parts by weight of infusorial earth; the former proportions forming, at ordinary temperatures, a dry, pulverulent mass, and the latter a pasty mixture. Let it be here observed, that the explosive force of the mixture is increased when a larger proportion of nitro-glycerine is employed, and that, when the mixture is to be used in a cold climate, a larger quantity of nitro-glycerine may be safely employed than when it is to be exposed to a warmer atmosphere.

"For ordinary practical purposes a mixture of 75 parts by weight, of nitro-glycerine, and 25 parts, by weight of infusorial earth, gives a powder sufficiently dry at ordinary temperatures, and which is susceptible to compression to a specific gravity nearly equal to that of pure nitro-glycerine. When the ingredients have been intimately mixed, and thoroughly incorporated by stirring and kneading, the powder is then ready for use, and may be packed in bulk in boxes, or compressed into cartridge cases made of paper, of such convenient sizes as may be most in demand for blasting purposes.

"In using this improved explosive compound for blasting, it may be inserted into cartridge cases, as above stated, or without any inclosure or wrapping as may be preferred. For the best effect it should be pressed firmly down so as to fill the bottom of the bore hole, always using a wooden rod for the charging of the hole. (Every miner is aware of the importance of having his charge of powder firmly set in the bottom of the hole). It is easily and efficiently exploded by means of an ordinary fuse inserted into the open end of a percussion cap, the metallic edges of the cap being compressed or crimped tightly and firmly around the fuse, in close contact with the fulminate in the percussion cap. The capped end of the fuse is then inserted into the explosive powder, which is pressed closely around it in the bore hole, and a tamping of sand or other suitable material may be placed above the charge of powder and pressed down upon it. The fuse thus applied is fired in the ordinary manner; and when the fire reaches the percussion cap, it explodes, which effects the immediate explosion of the charge of explosive compound."

Nobel's invention consists, therefore: "In the combination of nitro-glycerine with infusorial earth or other equivalent absorbent substances." Kieselguhr or guhr is found in Hanover, Germany. It is a soluble variety of silicious earth, is a white, mealy substance, composed of the silicious armor of a species of shells (*Diatomeen*) that form a multitude of small cells which possess considerable hardness and, looked at through a microscope, show their perfect state of preservation. This guhr possesses, as has been shown above, an immense absorbing capacity, and owing to the peculiar form of these infinitesimal small shells, every small particle of nitro-glycerine is, so to say, surrounded by it, and lies (is stored away) in a small cavity of this porous material in such a manner that these particles of guhr prevent the propagation of the vibration caused by a comparatively strong concussion. It can be said that each particle of nitro-glycerine is packed away separately in each particle of guhr in which it is retained by capillary attraction, and consequently the great objection against the liquid is in this way obviated.

At first the new blasting agent made but slow progress, owing in a great measure to the strong prejudice existing against its chief ingredient. But gradually it has grown into favor and numerous dynamite factories have sprung up all over Europe and America, and not less than a dozen were under the inventor's control, and what is more are on a paying basis.

It was not long after its introduction to the practical and scientific world, that it was universally adopted in both hemispheres, as it became an absolute necessity to the engineer and miner. During the last two decades, which are so eminently marked for the great advancement in railroad building, this material has been an immense aid in cutting the path for the great reformer of our modern age—the iron horse. And certainly the greatest credit is due to the inventor who has furnished us the means of accomplishing results, which might have been delayed for years had it not been for the excellent material which he has put into our hands.

The great success of dynamite has given rise to numerous other nitro-glycerine compounds, of which the most known are the Lithofacteur, Dualine, Hercules, Vulcan, Warren, Excelsior powders, which have entered into successful competition with Nobel's dynamite. The remark will be made here, that the object of these articles is not to say which is the best nitro-glycerine compound, but to impart to the reader the knowledge of what they are, as the miners on this coast are too intelligent a class of men to be told which is and which is not the best of these powders. Let everyone use his own judgment on that subject. It is self-evident that that compound which holds absorbed the greatest amount of nitro-glycerine in a pure and neutralized condition, will make the strongest, and consequently, the best powder. In some cases, where the absorbents used do not possess the great absorbing capacity of kieselguhr, the admixture of meal powder is resorted to, to add to the strength of the compound, be-

sides acting also as a vehicle to carry the nitro-glycerine.

The strength of dynamite, No. 1, is set down for equal weights to be as one to five, as compared with black powder, although in practice, some authorities set it lower, and some higher.

Dynamite forms a fine grain, somewhat pasty and fatty substance of gray brown color, which has, under the ordinary pressure employed to form it into cartridges, a specific gravity equal to liquid nitro-glycerine.

Against fluids and solutions it compares itself in the same manner as nitro-glycerine, only it must not be permeated by water, because it separates the oil from the guhr. Against heat it bears the same relation as nitro-glycerine. Dynamite burns in an open flame or on live coal with a quiet development of gases, but it must not be confined, and only when wrapped up in paper or other light substances, like wood; but in that case even there is danger of its being heated to the exploding temperature. Especially in storing large quantities, like in magazines, it can happen that during a fire an explosion can take place, as the mass may become heated to 380° before the same is burnt up. Such an accident happened in the dynamite factory at Hamburg on the 12th of July, 1866.

Against moderate strokes and concussion, such as may happen during transport, like the running together of the heavy box cars on railroad trains, jolting of freight wagons, dropping of case, the material is insensible, and although an instance is on record where during a collision a box car containing dynamite was all broken up, the boxes smashed and the powder split without explosion, it must be recommended to always handle this material with due precaution.

Some experiments as to its safety in regard to percussion are of interest:

A strong wooden keg containing 10 lbs. of dynamite put up in cartridges, was thrown from a height of 100 ft. against a rock, and the keg and contents remained intact.

To a flat stone weighing 200 lbs., a cartridge of dynamite was tied and then the stone dropped from a height of 20 ft. The cartridge was all smashed to pieces, but it did not explode. In spite of these reassuring results, which show the insensibility of the material against heavy percussion, we have on record some very distressing accidents, which have for causes the reckless handling of the same; and therefore let it be again repeated that although dynamite is a very safe substance when handled with ordinary care, it must not be forgotten that it is the highest explosive known, and that it ought to be treated accordingly.

In its frozen condition it is hard to explode, but even then it is to be recommended not to employ any pointed instruments for breaking it up, and in thawing it out to follow the ordinary rules which are known to every miner. It is very hard to explode frozen dynamite, consequently accidental explosions with the frozen stuff ought certainly be easily avoided.

It is hardly to be presumed that we will reach such a point in the manufacture or handling of explosive substances, as to dynamite, he it gun cotton, or be it gun powder, where claim can be laid to an absolute safety, as some accidental combination of circumstances will lead to explosions, and it is therefore the question, that under ordinary circumstances these accidental combinations should be avoided, which can be done by the exercise of care, prudence and precaution, and also by a perfect knowledge of the properties of the material, by the parties who handle it.

Dynamite has been in use in this country some 13 years; it has been shipped and transported over thousands of miles, been distributed in thousands of parcels in different parts of our Territories, under different atmospheric and climatic conditions, and, so far, spontaneous explosions of magazines are not on record as yet. Numerous distressing accidents have occurred, but from different causes, and consequently we presume the theory of scientific men, that dynamite does not explode spontaneously, to be correct, as the particles of nitro-glycerine are finely distributed through the kieselguhr, and if, during a storage of long duration, the nitro-glycerine decomposes the decomposition takes place slowly and gradually and does not lead to disasters.

I adopt the theory of scientific men that dynamite does not explode spontaneously, not because scientific men say so, but because practice has proven it up to this date, and it is to be hoped that future experience will bear out this theory.

As yet, I cannot consider the different dynamites as the perfect ideals of modern blasting agents, as they possess some disadvantages, which, no doubt, science will overcome in time.

1. The easy separation of the nitro-glycerine from the absorbents through water, which necessitates that it has to be put in water-tight cartridges when used under water for any length of time.

2. It gets hard at a comparatively high temperature; it freezes.

3. A more complete neutralization of its fumes, so as to make them less obnoxious.

THE iron giants of the Pennsylvania railroad company will be built this summer at Altoona. They will be much larger and more powerful than the ordinary passenger engines, and are to be built for the particular purpose of making up time in portions of the road where there are long stops.

### Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. F. OSBORN—San Francisco.  
A. C. KNOX—Sonoma, Napa, Lake and Mendocino counties.  
G. W. MCGREW—Santa Clara county.  
M. P. OWEN—Santa Cruz county.  
J. W. A. WRIGHT—Merced, Tulare and Kern counties.  
N. E. BORN—San Bernardino Co.  
JARED C. HOAG—California.  
B. W. CROWELL—Tehama and Butte counties.  
D. W. KRELLER—Santa Barbara, Ventura and San Luis Obispo counties.  
A. LEONARD MEYER—Utah, Idaho and Montana Ter.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals are of good vigor. A day at Woodward's Gardens is a day well spent.

A gentleman just arrived from Colorado who is thoroughly posted in the treatment of refractory ores, and who has been a director for 3 years in the Austrian Government Reduction Works in Europe, would like to engage his services to a Mining and Reduction Company, either as Superintendent or Assistant, or to take charge of the Assay Department. Address H. S., this office.

How to STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond this time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

THE State Mining Bureau, No. 313 Pine street, is open to the public from 10 o'clock A. M. to 5 o'clock P. M. daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

## Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

### DIVIDEND NOTICE.

OFFICE OF THE

Standard Consolidated Mining Company.

SAN FRANCISCO, MAY 2, 1881.

At a meeting of the Board of Directors of the above-named Company, held this day, Director No. 23, of Seventy-five (75) cents per share, was declared, payable on THURSDAY, May 12, 1881, at the office in this city, or at the Agency of the Nevada Bank of San Francisco in New York.

WILLIAM WILLIS, Secretary.

Office—Room No. 29, Nevada Block, No. 309 Montgomery street, San Francisco, Cal.

### NEW MINING FIELDS.

Prof. Hayden's Geological survey of the northern wilds, comprising his explorations in the Big Horn, Gray Bull, Yellowstone and Sun River Countries, Wind River, Teton and Little Rocky and Bear Paw Mountains. Their geology and physical features. Where the survey found "paying prospects," going from 6 to 25 cents in gold to the pan. Immense gravel bars prospecting 8 and 10 cents per pan. Water abundant for hydraulic mining. Extensive gold and silver bearing quartz lodes, one mammoth ledge as yielding \$15.90 in free gold per ton, from surface croppings. The classes of country rock peculiar to each section, which interest the miner, as being the most congenial for the existence of rich veins and placers. A valuable work (with map), forming a complete intelligible, systematic guide and companion for miners and gold hunters, desirable of prospecting in the northern Rockies and localities mentioned. Terms, \$5 per copy; 5 copies for \$20. Address J. A. CAMPBELL & CO., Evanston, Wyo. Ter.  
Box No. 119. [Mention this paper.]

## INGERSOLL ECLIPSE ROCK DRILLS.

The Most Economical Air Compressors in the Market.

## MINERS' HORSE-POWER.

One Horse can easily hoist over 1,000 pounds at a depth of 600 feet. The Power is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX,  
49 Fremont St. S. F.

## HUNTINGTON'S Oscillating Stamp Mill

It has no Stems, Cams, or Tappets, and Adjusts Itself to the Wear of the Shoes and Dies.

For Simplicity, Economy, Durability and Effective Working, it exceeds anything ever presented to the public, and will do the work of five stamps with one-fourth the power.

Price, 900-Pound Hammer, . . . \$500.  
Double Mills, . . . \$950.  
Price, 1200-Pound Hammer, . . . \$600.  
Double Mills, . . . \$1150.

## ST. DAVID'S, A FIRST-CLASS LODGING HOUSE

CONTAINS 113 ROOMS.

715 Howard St., near Third, San Francisco.

This House is especially designed as a comfortable home for gentlemen and ladies visiting the city from the interior. No dark rooms. Gas and running water in each room. The floors are covered with holly Brussels carpet, and all of the furniture is made of solid black walnut. Each bed has a spring mattress, with an additional hair top mattress, making them the most luxurious and healthy beds in the world. Ladies wishing to cook for themselves or families, are allowed the free use of a large public kitchen and dining room, with dishes. Servants wash the dishes and keep up a constant fire from 6 A. M. to 7 P. M. Hot and cold baths, a large parlor and reading room, containing a Grand Piano—all free to guests. Price single rooms per night, 50 cts.; per week, from \$2.50 upward.

R. HUGHES, Proprietor.

At Market Street Ferry, take Omnibus line of street cars to corner Third and Howard.

42 years' practical experience; 14 on Pacific Coast.

## HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - - San Francisco, Cal.

## \$1,000 CHALLENGE!

## THE FRUE ORE CONCENTRATOR.

Over 250 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institutes of San Francisco, Cal.

Saves from 50 to 100 per cent. more than any other Concentrator in use, and the concentrations are clean from the first working.

The wear and tear are merely nominal; the water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of \$1,000 each, and we mean business.

ADAMS & CARTER, Agents, Room 7, No. 109 California Street, S. F.

## GIANT POWDER

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS.

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive

## Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. 1/2 Triple Force Caps and all Grades of Fuse.

**BANDMANN, NIELSEN & CO.,**  
SAN FRANCISCO, CAL.

## "FRUE" ORE CONCENTRATORS.

I have on hand and for sale, at LOW PRICES, a number of the above Concentrators, of the latest pattern and in perfect order.

JOSHUA HENDY,

Manufacturer of Quartz and Saw Mill Machinery

AGENT FOR "BAKER'S" ROTARY PRESSURE BLOWERS,

Hot Polished Shafting from the Akron Iron Company, Ohio. Also, "P. Blaisdell & Co.'s" Machinists' Tools. A Large Stock of New and Second hand Machinery at Machine Works.

Nos. 49 and 51 Fremont Street, San Francisco.

FOR SINGLE OR DOUBLE SHAFTS, TO WORK TO ANY DEPTH, OF LATE AND IMPROVED DESIGNS, SUPERIOR TO ANY OTHER MAKE; ADAPTED TO THE REQUIREMENTS OF PRACTICAL WORK AND EMBRACING ALL THE IMPROVEMENTS AND SAFEGUARDS THAT EXPERIENCE HAS PROVED VALUABLE IN THIS CLASS OF MACHINERY. MINING CAGES, CAR AND BUCKETS, ALSO MILL AND MINING MACHINERY OF EVERY DESCRIPTION. SEND FOR CIRCULAR. RANKIN, BRAYTON & CO., PACIFIC IRON WORKS, SAN FRANCISCO, CAL.

J. H. WYTHE, M. D.

Residence: 955 West Street, Oakland. Office: 759 Market St., San Francisco.  
Before 10 A. M., after 5 P. M. From 11 A. M. to 3 P. M.

TUBBS & CO.,

611 and 613 Front Street, San Francisco

## THE PELTON WATER WHEEL.

(Patented, Oct. 26, 1880.)

This water wheel has been thoroughly tested with the Dynamometer, and utilizes 78% of the theoretical power; and underheads of water of 75 to 800 ft is guaranteed to give better satisfaction than any Turbine or other wheel ever offered to the public. The above per cent. is due to the peculiar shape of the buckets used. They do not reduce the water to a spray, but divide and deflect it outward and backward, in such a manner that a part of the impact and the whole reactionary force are utilized, without any part of the water coming in contact with the bucket following. Furthermore, the per cent. of efficiency remains constant through great variations in the amount of water used. These buckets can be taken off in transportation, and can be replaced by new ones when worn out by sand in the water; also can be applied to wooden wheels when desired.

SEND FOR CIRCULAR.

Orders can be filled at short notice by addressing the undersigned,

L. A. PELTON,

Camptonville, Yuba Co., Cal.

## EXCELSIOR BLASTING POWDER

MANUFACTURED BY THE

Excelsior Powder Company.

This is an so-called "safety" Powder, but a powerful explosive, and as safe to handle and use as any nitro-glycerine Powder on the continent. There is no headache or nausea in the use of this Powder, as the noxious fumes are entirely done away with. It is put up in cartridges of any size to suit consumers and is exploded with cap and fuse, the same as any other high explosive. The following testimonial is a sample of hundreds of the same tenor being constantly received:

GOLD HILL, August 17, 1880.

AGENT EXCELSIOR POWDER CO.—Dear Sir:—I have used your Powder in wet cement and hard blasting rock, and find it superior to any Powder in use on the Coast. It does its work effectively, and does not leave the person using it with a severe headache, like the other Powders used to the majority of miners. In recommending it I would suggest, give it a fair trial and I am confident it will speak for itself. Wishing your Company success,  
I am respectfully yours, etc.,

GEORGE CLARK,

Foreman Sierra G. and S. M. Co.

Address all orders to

**Excelsior Powder Company,**

Room 40, Merchants' Exchange,

SAN FRANCISCO, CAL.

## EXOTIC GARDENS.

Mission Street, opposite Woodward's Gardens; Branch, 1029 Sutter St. These Gardens have been Newly Stocked with a First-class assortment of the very best and most select plants for Conservatories or Open Grounds.

Prices have been reduced to suit the times. Bouquets, Funeral Works and Cut Flowers furnished at short notice.

J. POUYAL, Proprietor,

All are invited to examine our stock.

Scientific Press

Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old  
experienced, first-class Agency. We have able and trustworthy associates and Agents in Wash-  
ington and the capital cities of the principal nations of the world. In connection with our edi-  
torial, scientific and Patent Law Library, and record of original cases in our office, we have  
other advantages far beyond those which can be offered home inventors by other Agencies. The  
information accumulated through long and careful practice before the Office, and the frequent  
examination of Patents already granted, for the purpose of determining the patentability of  
inventions brought before us, enables us often to give advice which will save inventors the  
expense of applying for Patents upon inventions which are not new. Circulars of advice sent  
free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

# "THE \$1,000 CHALLENGE"

## Ore Feeder for Quartz Mills.

OVER 800 ARE NOW IN USE, GIVING ENTIRE SATISFACTION.

Awarded First Premium at the Tenth and Twelfth Industrial Fairs of the Mechanics' Institute.  
Twenty Per Cent. More Ore Crushed with Fifteen Per Cent. Less Wear of Iron than by Hand Feeding.

The accompanying cut illustrates the recently introduced Grip, and also the Spring Attachment, which replaces the Weight heretofore used, and which are obvious improvements.

It is now fully demonstrated, after careful and long continued experimentation and practical use, that the plan upon which a perfect Ore Feeder must be constructed is that of a carrier, and not that of a shaking-table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Jerky or spasmodic contrivances will not answer the purpose for wet or sticky ores.

The Challenge Ore Feeders are now in use in the following Mills, besides many others:

Superiority of the "Challenge" Ore Feeder Demonstrated!

At the "Christy" Mill, Uintah County, Utah, the "Eclipse" Feeders, (conceived by E. Coleman) were introduced, but not carrying a regular supply of ore for the crushing capacity of the stamps, were replaced by the "Challenge," which are now running and the stamps crushing forty (40) per cent. more ore than was done by the "Eclipse."

The "Harshaw" or "Hermosa" Mill, of Patagonia District, Arizona, was also originally fitted with "Eclipse" feeders, but after a few weeks trial they were pronounced inadequate to the work, discarded, and the "Challenge" dopted.

The "Silver King" Mill of Arizona, also removed the "Eclipse" Feeders to give place to the "Challenges."

The "Sola" Mill, of Brown's Valley, Yuba County, Cal., was fitted with "Victor" Feeders, manufactured by E. T. Steen, but proving insufficient, the "Challenge" Feeders were substituted.

Four of the "Victor" Feeders, manufactured by E. T. Steen, were also placed in the "Alexander" Mill, at Grantsville, Nevada, but after a fair trial were discarded, and Hendy's Feeders fitted, and four others of the same pattern added when the second twenty stamps were erected.

These cases are simply cited from among many similar instances, in proof of the vast superiority of the "Challenge" Feeders over all others.

Mr. H. W. GREENWELL, of the Tingman Mine, El Dorado Co., or any other person can make \$1,000 by disproving the acknowledged superiority of my "CHALLENGE" Feeder, in a competitive trial, side by side, with any other Feeder, on wet or sticky ores from any mine, and I will give \$100 to any one who will procure the acceptance of this challenge, and arrange for a fair and impartial test on merit.

I mean business, Gentlemen, "either put up or shut up."

## JOSHUA HENDY,

## Emery Wheels.

The growth of mechanical invention is a wonder of this wonderful age. In every sphere of industry the application of labor-saving tools is the dominant ambition, and the wise artisan carefully calculates the possibility of employing machinery in the production of his goods so as to reduce to a minimum the actual cost in time and labor. The tools of a quarter of a century ago are even now so far eclipsed, in many departments, that with their use it would be impossible to keep abreast of requirement. This is especially true of sharpening, shaping and grinding tools. What a ridiculous absurdity the file is, compared with a Tanite emery wheel! How pitiful it is to reflect that men were compelled to devote days and weeks of exhaustive labor with a clumsy rasp, to what may now, by easy manipulation, be more neatly and satisfactorily accomplished with an emery wheel in a few minutes.

The emery wheel is a king among inventions. It is emphatically "the Jack of all trades," and "master" of them as well. With the aid of a diamond tool the Tanite emery wheel can be turned in a very few moments to fit any desired shape—convex, concave, beveled, etc., etc.—cutting the exact reverse of its own, so as to meet any possible requirement. The failure to add this universally applicable tool to a well-stocked mining plant is more than unfortunate.

In mines remote from manufacturing centers, it will save inconceivably in time and annoyance. Suppose some part of the machinery breaks, as the best-made machinery will do—the hoisting gear give out, the pumping apparatus get out of order, the rock drills need repairs, or what not—having one of these wheels at hand, it is not necessary to send the broken shaft, or wheel, or valve, or pulley, or whatever, to a distant machine shop, and have the works shut down for several weeks, till duplicate pieces can be furnished or the broken ones repaired;—it is a machine shop in itself. With a diamond tool, the cost of which is a bagatelle, it is quickly put into shape, and any desired result is speedily effected on the spot without the annoyance of any perceptible delay; a saving of time and money miners will appreciate.

In the development of Mexican mines, where hitherto only the crudest appliances have been employed, the very best machinery is now being used. This is notably so of the Rosario mines, operated by an organization of New York capitalists, of which the Governor of New Jersey is President. But as these mines are so far inland, the neglect to furnish the costly and magnificent plant, provided by the enterprising company, with a full outfit of these wheels and grinding machinery, would seem to be almost unpardonable. Even in close proximity to machine shops these wizard wheels are an absolute necessity, and save incalculably in time and labor to the intelligent operator; but in cases like that just suggested, it is foolhardy to be without them.

What is thus significantly true of these wheels in mining districts is more than ever true in the great lumbering regions of Washington and Oregon. C. T. Doxey & Co., of Anderson, Ind., write: "When we break several teeth out of our saw, we can cut them all off and cut new teeth in the saw in less than eight hours, and at a cost of \$2.50; whereas it cost us from \$10 to \$12 before we commenced using the Tanite emery wheel. Besides it would take from three to six days to get it done, as we would have to ship it off and await its return. We have seen many a time that we would have lost from \$50 to \$100 had we been without them, in the way of losing time."

John Heuxhurst, of Alexandria, Va., writes: "Our former practice was to file the teeth so as to simply keep them sharp, and when they became too short, send the saws to the manufacturers and have them gummed. When the saw was in constant use this would occur once in about two months and a half, at an expense of from \$15 to \$20, including express charges. By the use of a Tanite emery wheel this is not required, and much is saved in files. There is also a gain in the amount of work by their use. When the saws are sent to manufacturers we have the teeth made as long and slender as they will bear, to save files and time in

filig, and they are not in the most efficient condition till partially worn, and they are also used some time after the teeth are too short to cut easily. By the use of an emery wheel, saws may be kept constantly in their most efficient condition." This is the experience of practical sawyers in the vicinity of manufacturing towns. The advantage of an emery wheel in the hands of an expert sawyer in those western wilds is simply incalculable. It is undoubtedly the indispensable belonging of the modern sawmill plant.

The Tanite company also manufacture grinding machines for the efficient application of their wheels, and are constantly inventing and constructing new styles for specific uses, to meet the ever increasing demands of the various industries.

Their extensive works are located at Stroudsburg, Monroe county, Pa. They conduct their business, however, in their own name under the management of their agents, the well known gentlemen, H. P. Gregory & Co., whose establishments are at 43 Front street, Portland, Oregon, 2 and 4 California street, San Francisco, and 11 Pitt street, Sydney, N. S. W., and who

THE TANITE CO'S REVERSIBLE-REST SINGLE-WHEEL GRINDER.

from these centers can supply the entire Pacific coast and Australia.

We give on this page an illustration of one of the Tanite Co.'s machines. It is a reversible-rest, single-wheel grinder. This machine stands on the floor, to center of arbor 37 1/2 inches. It is especially designed to meet the requirements of machine shops where only one wheel is desired, and also adapted for sharpening and gumming saws.

The last party of government surveyors who came through this part of the country, says the *Virginia Chronicle*, made a scientific examination of the Comstock lode, and after microscopic inspection gave the principal rocks their true names. The footwall, or western wall of the vein, they call diorite, and the hanging, or eastern wall, diabase. The vein matter is pronounced to be a mixture of diabase, diorite and quartz. Hereafter the Comstocker who desires to be strictly correct in his language must bid good-bye to such old-fashioned expressions as bird's-eye porphyry, propolyte, syenite and the like.

It is reported that the late strike in the Horn Silver, Utah, is very rich, the ore assaying 450 ounces silver.

## Re-Locations and Expenditures.

The status of re-located mining claims, forfeited because the required expenditure was not made, is rapidly being determined. There have been many questions connected with these re-located claims; questions plain enough when applied to original claims, but difficult to answer when applied to the re-located ones. In another column we give a decision which determines that any one of a company can re-locate for himself alone a claim abandoned by the company. But the commissioner decides, also, that the labor performed or improvements made by an original locator cannot be claimed by him as part of the expenditures necessary to entitle him to patent for the re-location.

Such a re-location being decided to be valid, the question was, could the re-locator claim the amount of money actually expended by himself for work on the original location as part of the expenditures required by law to entitle him to receive patent for the claim so re-located.

The commissioner very properly rules that

## The Railroad Commission.

The May meeting of the Railroad Commissioners, at which certain important matters were expected to transpire, has been held and there is no change in the condition of affairs. General Stoneman is at open variance with Messrs. Cone and Boerstecher, and as the latter constitute a majority of the commission they propose to proceed to carry out their plans, which is to recommend the schedule of rates arrived at by some kind of consultation between the commission and the railway managers. It does not appear that the new schedule is based upon anything but generalizations, and the essence of the reduction seems to be in the fact that the railway managers will accept it, and thus the public will be saved the cost of law suits.

But it does not appear that the commission is able to agree. There is often some inharmonious spirit to disturb the pathos of the sweetest scene, and intruding upon the betrothal between the commission and the railroads, with such grating words as these:

I believe in a vigorous and persistent policy, lawsuits or no lawsuits. Certainly if the Constitution contemplated a purely peace policy it would not have directed us to go to the courts to enforce our decisions, nor would the Legislature have furnished us with a fund to fee attorneys. I have stated repeatedly that in all probability we should have to go into the courts to enforce any decision made, and I presumed it would take time to carry them into effect. President Stanford told us very frankly and plainly that he would not obey us, and I presumed he meant what he said. But is this Commission to be deterred from the performance of its duties by any such threat? I have also often remarked that the first thing to be decided was as to the possibility of subordinating railroad corporations to control, and until that question was settled and decided we of course were powerless to do anything, and that I was in favor of having the question settled at the very earliest possible period, and that we should avail ourselves of every means placed at our disposal to carry out the law.

How rude to speak of control and subordination so close to the altar. Surely Gen. Stoneman could have withheld his insinuation that either party to so sweet a contract could dream of controlling the other until the wedding bells had ceased their clangor. But the deed is done, and, though the union will be duly proclaimed, there will still be some people who will look for disaster to follow so cruel an omen.

But, in all seriousness, the result of the work of the commission is altogether unsatisfactory thus far, and comes far short of the task set before them by the people. Nothing is settled which is at all essential to the question. The majority of the commission argue that the railway managers show fitting appreciation of the rights of the people. They have reduced their charges before and will reduce them again as fast as the growth of the country warrants reduction by increasing the traffic. Now it does not make the slightest difference in the world whether this is true or not. It might have made a difference before the commission was created, because then the framers of the Constitution might have thought a commission unnecessary, but now, that the commission is ordered and equipped, it makes no difference whether the railroads are enterprising or not. Unless all the evils which the people complain of are removed it is the duty of the commission to investigate them, to arrive at the best possible conclusions, and then take measures to enforce them. If they stop short of this, leave their strength untried and merely accept what is given them irrespective of whether it is a right or a favor, they have fallen short of their duty.

We do not advocate any summary proceedings or measures adopted without due reason. We should not propose any unintelligent chiseling of rates or fares. Such action would work hardship perhaps to the companies, and thus would result in public detriment. But it has been shown that there are ways of arriving at what is fairly due a transportation company for certain services, and it is the public right that such measurement of values really earned should be applied. If the companies deny the right of the people to exercise this control over their operations, then the question of superior rights must be tested. This is what the commission was organized for; and if the present members of the commission do not discharge the duty entrusted to them, their successors will, or the people will know the reason why.

DISCOUNT ON BULLION.—The Sheriff has advertised for sale the Arizona Mining Company's property, at Unionville. This property was at one time valued at \$1,000,000, and the mine produced in a few years some \$3,000,000 worth of bullion. It is said by practical miners who have worked in the Arizona mine, that it is yet valuable, and that there is good ore in sight in the mine. The discount on bullion was the principal cause of the failure of the company, as in the past few years it amounted to over \$40,000.

## Copper Smelting—Its History and Processes.—No. 5.

[By HENRY HUSSEY VIVIAN, M. P.]

In all copper smelting, the first object must be to lose as little copper as possible in the slag, and to make the fusion easy. To this end, the copper smelter anxiously considers the varying nature of his ores. Some contain large quantities of sulphide of iron; these he takes care to roast or calcine highly, in order to obtain oxide of iron wherewith to flux the silicious matter of other ores and to produce a regulus sufficiently rich in copper, his standard in that respect being from 30% to 35%. Some ores containing much earthy matter he finds will not pay for calcining; that is, if he has plenty of ores of the first-named class at his command. The extent to which he calcines his ores depends on their nature and the proportion which one sort bears to the other, his object being to produce in his first melting a regulus, that is, a combination of copper, iron and sulphur, of not less than 30% or more than 35%. Not less than 30%, because if less, the subsequent processes are rendered more costly by the increased quantity which has to be treated; not more, because each pill which is held in mechanical suspension in the slag is richer in copper, and thus increases the loss, while there may even be some danger of getting oxide of copper into the slag. Now, whether this process is conducted in a reverberatory calciner, in a Gerstenhoffer, in a muffle (of which more hereafter), or in heaps as before explained, the objects to be attained are the same in all cases. The merits of the different systems of calcining or roasting may be shortly stated thus: The most ancient, namely,

### Roasting or Burning in Heaps,

Is the least costly, provided the ore is sufficiently rich in sulphur or bituminous matter, as in the case of the Mansfeld Kupferschiefer; but it is not applicable to ores poor in sulphur, and in any case it is very tedious, occupying weeks, or even months, and therefore necessitating enormous stocks of ore in comparison with the quantity treated. The South Welsh calciner, on the other hand, is rapid in its action, never exceeding 36 hours, and for ordinary ores 12 hours, while the quantity treated is considerable and the cost of coal and wages consequently small. Our large calciners at Hafod treat 14 tons each charge, the time of course depending on the nature of the ore we are operating on. It is, I may assume, well known to all whom I am addressing that calciners are long and wide reverberatory furnaces; ours are 28 ft. long by 13 ft. wide (inside measurement), with a comparatively small fire-grate at one end; that the ore is spread evenly over the bed of the furnace, and is occasionally stirred or "padded;" that is, lifted with a flat, spade-like tool, so as to expose fresh surfaces to the action of the flame, which passes in rolling waves along the roof, a stratum of atmospheric air intervening between it and the ore, which supplies the necessary oxygen to combine with the sulphur, arsenic, and other volatile minerals, which are thus enabled to form their respective acid combinations and to pass off in the gaseous form, while the iron and other metals become oxidized. This calcining furnace is simple and under complete control. Any ore can be treated in it, and the process can be arrested at or pushed to any desired point. In this furnace, the sulphur gases are wasted, because they are diluted by the excess of atmospheric air present in the furnace, and they are at the same time rendered impure by admixture with the products arising from the combustion of the coal used for heating the calciner. It has, therefore, never been practicable to utilize the sulphur gases of ordinary calciners for the manufacture of sulphuric acid. In some copper works, calciners with double beds are used. I have tried them, but have found no advantage to arise from them, while they are more costly both in erection and repairs. I have now to notice

### Calciners

Adapted to the production of strong and pure sulphur gases for conversion into sulphuric acid. These are of three kinds, namely: Kilns in which the material is burnt in pieces of the size of road metal; the Gerstenhoffer calciner, in which it is burnt as powder; and the Muffle calciner, which is worked by transmitted heat. I believe other systems have been proposed, but I am not aware that they have been proved to be of practical value.

The Kiln system of burning is applicable only to material very rich in sulphur, say 20% and upward, and in a rough state. It is the system universally adopted in alkali and sulphuric acid works for the treatment of pyrites rich in sulphur and iron and poor in copper. I cannot state the exact limits within which this system is applicable; but I know of instances in which ore as low as 23% of sulphur has been burnt. This system is at once the cheapest and most complete wherever it is applicable.

I next come to the beautiful

Invention of Mr. Moritz Gerstenhoffer, And now known by his name. This invention was brought to my notice by the late Mr. Hermann in 1865. I at once saw its practicability, and caused two experimental furnaces to be built. They were found successful. We purchased the patent, and shortly afterward erected 43 calciners, more than sufficient to treat all our ores and regulus which were sufficiently sulphurous to admit of being thus dealt with. After 15 years' experience, I can say Mr. Gerstenhoffer's invention is still a success. The principle upon which it is based is the same as that of the alkali-maker's kiln, namely, that

the heat of the furnaces should be maintained by the combustion of the sulphur of the material under treatment, and that no more atmospheric air shall be admitted than is necessary to maintain such combustion without fusion of the material, while the resulting sulphur gases shall be strong enough to be available for the sulphuric acid chamber. The alkali-maker was limited to the use of rough material. Mr. Gerstenhoffer solved the problem of using fine material. He constructed a vertical furnace 14 ft. high, 4½ ft. wide, 2½ ft. deep (inside measurement); he placed across it fire-brick bars of triangular form, presenting one flat surface to the horizontal plane, and so arranged in rows above each other that the edges of the higher triangle should coincide with the center of the triangle next below. He heated his furnace to a good red heat by a coke fire temporarily lighted in the lower portion, and when at full heat he withdrew the coke and fed mechanically, through slits in the top, a constant and regular stream of the sulphurous material under treatment which, falling on the highest rows of cross-bars, formed a cone on each, and then fell to the next bar beneath, and so on until each bar of the 70 contained in the furnace received its full charge, while the sulphur in both the falling material and that which lodged on the bars became ignited and burnt by aid of the atmospheric air admitted through holes in the front of the furnace, arranged just above the top of each cone of ore, thus keeping up the heat by the combustion of its own sulphur, and giving off pure and strong sulphur gases, sulphurous with some sulphuric acid. By this simple and beautiful arrangement, the problem of burning fine sulphurous ores and regulus, which had puzzled many a wise head, was successfully solved. I hope from the description I have given that the operation will seem plain and clear to the minds of my hearers, probably far simpler than we have found it in practical working; for I may say that we have only just arrived at what I consider satisfactory working; and when I say "we," I desire to acknowledge the zeal and intelligence which Mr. William Morgan and his son, Mr. William Edward Morgan, have displayed in perfecting this system. For example, I see that when I gave evidence before the Commission on Noxious Vapors, in April, 1877, I produced figures showing that we had during the previous year condensed and made into sulphuric acid 37.93%, say 38%, of the sulphur contained in the whole of the ores we treated; while from figures just furnished me by Mr. Morgan, based on calculations precisely similar to those contained in my answer (10,906), I find that during the year ending July, 1880, we condensed and made into sulphuric acid just 47% of the sulphur which was contained in all the materials treated at the Hafod Works, showing an improvement of about 25%. Again, in that evidence I stated our consumption of niter at 4.53% upon our oil of vitriol, whereas it has now been reduced to 3.3%, mainly by the use of the Glover and Gay-Lussac Towers. I remember when it was 7%; and when our then manager, upon my complaining of this excessive consumption, assured me, and proved by abstruse chemical calculations, that it could not be reduced, my reply was: "Never mind chemical formulae; if you can't reduce it materially I shall take it in hand myself." We are still a long way off the niter consumption of kiln-made acid, which does not exceed 1.3%. I despair, however, from various causes, of ever reaching that low consumption. When I state that we condensed last year 47% of our sulphurous gases, and lost 53%, it must, of course, be understood that I refer to the whole products we treated, many of which are unsuited to the Gerstenhoffer, or any other close calciner. That loss is chiefly due to the melting furnaces and to the last process of roasting white metal into copper. That metal melts at so low a temperature that it is extremely difficult to calcine without running it together, unless an excess of air is present. In a lecture of this nature, which is intended to give a general and popular rather than a scientific account of copper smelting, it will not, I think, be expected that I should dwell at greater length on this or any other single process. Those who desire to see an account of the Gerstenhoffer calciner in more detail, will find it in the evidence I gave before the Noxious Vapors Commission in 1877. It may be interesting to state that we last year condensed 3,666 tons of oil of vitriol (concentrated sulphuric acid), which would otherwise have gone into the atmosphere, and been wasted.

I now come to the third and last system of calcining furnaces adapted to the manufacture of sulphuric acid from copper ores or regulus, namely,

### The "Muffle Calciner,"

Which, in external appearance, is very much the same as an ordinary copper calciner of the old form; internally, however, it differs considerably, since the material under treatment is inclosed in a chamber of fire-brick, constructed by arching over the inner space in such a manner as to cause the products of combustion to pass over and under the ore-bed, and transmit the heat through the fire-brick. By this means, the sulphurous gases are obtained free from admixture with the coal gases, and no more atmospheric air is admitted than is necessary for the production of sulphurous acid and the oxidation of the iron, etc. I have no practical experience of muffle calciners, because I never thought well of them, owing to the expense of fuel consequent on working with transmitted heat, and the dilution of the sulphur gas when the door is taken down for stirring.

(TO BE CONTINUED.)

## The Cost of Milling Silver Ores in Utah and Nevada.—No. 2.

[Read before the American Institute of Mining Engineers by R. P. ROTHWELL, M. E., New York City.]

[Mr. Rothwell now goes on to describe the Stetefeldt furnace and feeders, etc., but as most of our readers are familiar with this, we omit the description. We also condense the remainder of Mr. Rothwell's paper.—EDS. PRESS.]

The following table gives the average cost per ton in labor and material for treating Ontario ore. These figures are kindly furnished me by the superintendent of the company:

ACTUAL RUNNING EXPENSES OF WORKING ONTARIO ORE, ESTIMATED FROM A PRODUCTION OF FIFTY TONS PER DAY.

No. Men	Occupation.	Per day.	Per Ton
1	Foreman.....	\$10.00	20
1	Assayer.....	6.00	12
3	Machinists (4).....	12.00	24
2	Carpenters (4).....	8.00	16
2	Blacksmiths (4).....	8.00	16
2	Engineers (4).....	8.00	16
2	Foremen (8½).....	7.00	14
9	Dry floor (3½).....	81.50	63
3	Battery (4).....	12.00	24
6	Boastmen (4).....	24.00	48
12	Cooling floor (4).....	48.00	96
4	Carmen (4).....	16.00	32
4	Amalgamators (4½).....	18.00	36
1	Retorter (4).....	4.00	8
1	Melter (4).....	4.00	8
4	Laborers (2½).....	10.00	20
4	Watchmen (3).....	12.00	24
3	Ore floor (3½).....	7.00	14
3	Clerks (4).....	12.00	24
66		\$257.50	\$5.15

### SUPPLY.

	\$5.00	\$30.00	\$1.60
Salt, 10 tons.....	.50	87.50	1.75
Quicksilver, 175 lbs.....	4.50	67.50	1.35
Wood, 15 cords.....	8.25	99.00	1.50
Coal, 12 tons.....			.25
Castings.....			.25
Oil and waste.....			.25
Sundries, chemicals, etc.....			.40
Hauling from mine.....			.40
Charcoal, assaying & melting.....			.25
			\$9.87

The above items, aggregating \$15.02, are not, however, the total expense of milling; there is general superintendence, office expenses, repairs, insurance, etc., to be added to this.

### Cost of Milling Silver Reef Ores.

I will cite an example of what are probably the easiest milling silver ores in this country, viz.: those of Silver Reef, Utah. These ores are silver-chloride impregnations of sedimentary sandstones, which crush so easily that a 750-pound stamp will crush through a 40-mesh screen an average of from seven to eight tons per 24 hours. The mills in the Silver Reef district are all small, containing only 5 and 10 stamps, and though they contain as much as 12 pans, with a capacity of 1½ tons to the head of stamps, the battery capacity is in all cases greater than that of the pans. Some of the mills have averaged the month through 8½ tons to the head of stamps; nor does that appear to be a maximum limit. The ore under the stamp disintegrates and passes rapidly through the screens as fine sand; indeed it seems probable that Cornish rolls would crush this ore fine enough for amalgamation, and would do so with wonderful rapidity. As the ore is also remarkably pure, no impurity except a little copper, which occurs in a few of the mines, is found in the hullion. The cost for chemicals is also extremely low. Considering the fact that the mills are so small, and that some of the items are therefore necessarily high, the cost of milling is the lowest of any silver ores in this country:

	LEWIS CO. in 1878.	STORMONT CO. in 1878.	CHURCH M. AND M. CO. in 1878.
12,000 tons.....	\$2.20	\$2.20	\$2.20
9,000 tons.....	\$2.20	\$2.20	\$2.20
14,240 tons.....	\$2.20	\$2.20	\$2.20
Per ton of 2000 lbs.....	2.1	2.1	2.1
Labor and salaries.....	1.22	1.22	1.22
Bluestone.....	.55	.55	.55
Mercury.....	.31	.31	.31
Salt.....	.12	.12	.12
General supplies.....	.41	.41	.41
Incidental.....	.12	.12	.12
Hauling.....	.84	.84	.84
	\$5.12	\$5.12	\$5.12
	2.00	2.00	2.00
	\$7.12	\$7.12	\$7.12

Stormont mill is driven by water-power.

The tailings vary greatly in richness according to the character of the ore milled. From sandstone ore they will carry \$3 per ton, while from the shale ore they may run \$10 or more.

### Milling Comstock Ores.

There has always been a great difficulty, not to say impossibility, in getting reliable figures as to the cost of milling Comstock ores.

The following particulars, though not taken from the books and not "official," are still, I believe, so near the inaccessible "bottom facts" that they may be of interest. The data were collected with care, both during a visit to the mill and afterwards from well-informed sources.

The California mill, Virginia City, is one of the finest in the world and is admirably man-

managed; it contains 80 stamps, which fall 7 to 8 inches, and make 90 to 100 drops per minute. The ores are very easily crushed, and the full capacity of the mill is estimated at 360 tons per 24 hours, or 4½ tons per head of stamps per day; probably the average work is 320 tons a day or 4 tons per stamp; the stamping is done wet. The stamps are fed automatically, and the total number of men employed in the stamp mill per 24 hours is 12, namely, 2 engineers, 4 feeders, 2 firemen, 2 repairers, and 2 binmen.

From the stamps the ore runs through a trough to the pan-mill, situated at some distance down the canyon. In this there are 40 pans running on ore and 4 pans on tailings. The average charge of pane is 3600 pounds of ore worked in 5 hours; the millers run about 90 revolutions, and bear on the bottom or grind. From 12 to 24 lbs. of salt, and about one-third as much bluestone (sulphate of copper) is added to the charge, and after 3 hours grinding 350 lbs. of mercury is added. These quantities vary with the richness and character of the ore. The average loss in mercury is from 2 to 2½ lbs. per ton of ore. The settlers (20) run about 18 revolutions and 2½ hours, and their tailings run into the agitators and thence over the blanket sluices. The labor in the pan-mill per 24 hours is 6 amalgamators, 20 tank shovellers, 2 pan shoers, 2 amalgam-men, 2 engineers, 2 firemen, 5 woodmen, 3 repairers, 3 oilers, 1 retorter, 1 extra roustabout, 1 lamphoy, 2 night watchmen, 2 foremen, 1 superintendent—total, 54 men.

The tailings form about 10% of the ore and are reworked in the tailing-mill, and then run over blanket sluices; this requires 2 amalgamators, 4 shovellers, 1 cartman, 7 blanket-men, and 1 horse blanket-man—15 men. Total in stamp, pan and tailing mills, 81 men per 24 hours; the wages are from \$3 to \$4 per day. The fuel consumed per 24 hours in the battery mill (360 tons) is 80 to 90 cords, and in the pan and tailing mills (360 tons) 38 to 40 cords; total 120 to 130 cords at \$10 per cord.

There are two sets of blanket sluices, each of 6 tables, 300 feet long, with a grade of about 2½". In the first set ¾ of all the tailings recovered is caught, and ¾ in the second set. About 8% of the stamped product is saved in these sulphurets, which assay sometimes \$20. These blanket tailings are mixed with from 3 to 10 pounds of salt per ton, exposed to the air, and then mixed with the tailings of the settlers in the agitators, and the mixture averages, I am informed, about \$7 per ton.

### Gathering Eucalyptus Seed.

EDITORS PRESS:—I would like some information through your paper about the seeds of the Australian gum tree, where they are to be found, what they are to be gathered, etc. We have some trees that are about six years old, and one of them has blossomed during the last two years. There is something that looks like seed on the ends of the fine down of the blossom, and there is something which looks like seed in the little cup under the blossoms. Please give me some information on this subject.—SUBSCRIBER, Sand-Cut Station.

EDITORS PRESS:—I scarcely consider myself competent to fully answer the above, and do it intelligently, as the genus eucalyptus comprises a great many species with which I am not acquainted except through the writings of scientists. Supposing your correspondent has the species more generally known here, *E. globulus*, or blue gum,—the seed may be found, not on the ends of the tasselled flower, but within the seed cup, and resembles black onion seed. The seed cup has four and five cells, running longitudinally from the lower end of the cup up to the stem, and as the seed approaches maturity the opening of these cells gradually expands, the chaff drops out, and lastly the black seed, which is usually in the upper ends. The seed matures the season following the season of flowering; therefore it requires one year to form and ripen the seed before it is fit to gather.

As to the time to gather the seed, much depends on the season. If a cold one it will not be fit to gather before June; if a warm one, in April. It must be remembered the cups always shed or drop the seed before they dry and drop off, and any that do drop off before the cup is containing the seed open are worthless. All the cups do not have seed in them. Usually those of four cells are the most certain, and contain finer seed and more of it. Some trees have little or no seed on them, though full of flowers. In others every cup will contain from 20 to 100 seed. Again on some trees none but the four-celled cups will contain seed; on others both the four and five-celled will have them.

There are sections of the eucalyptus family that are quite different in many respects to the blue gum. The red, the iron bark, the white, the weeping, and many others have seed very fine, so small that no attempt is ever made to separate it from the chaff, and the best way to test the point in these fine-seeded varieties is to gather the little cups, place them in a warm place on a paper, and soon the chaff and seed, if there is any, will shake out together. Now take a piece of white flannel, wet it thoroughly, scatter the chaff over it, fold it up and lay it in a sunny window. Keep it continually moist—dripping wet. In three or four days the little seed will germinate. Look sharp, for in some of the species the tiny seed germ is so very small, the least speck, that it takes a keen and practiced eye to know it.

To answer your correspondent's question fully would require several columns in the PRESS. I have been as brief as possible, but if in my brevity I have failed to be clearly understood, will cheerfully give further explanations.—W. A. T. STRATTON, Petaluma, Cal.

## MECHANICAL PROGRESS.

## Driving Tubular Piles.

It is well known that there is great difficulty in driving tubular piles, but Le Grand & Sutcliffe, of Banhill Row, London, have introduced a new method by which the piles are driven internally at the bottom instead of externally at this top. The system is described in the *Building and Engineering Times*:

The piles are applicable as foundations for heavy structures, or they may be used for the lightest, such as posts or railings. The blow is delivered exactly where it is wanted, being at this point; this is effected by inserting into the tubular pile one end of a cylindrical driving monkey. This is then raised two or three ft. and then allowed to fall upon the flat head of the solid point, the pile itself forming the guide for the driving weight. Almost any length may be used; and in the case of wells, when a great length of pile is often required, they can be lowered through the water length by length, connected together by screwed sockets, until the solid ground is reached. When it is used for poles, posts or columns, the process of driving it into the ground occupies but a few minutes; and when this pole to be bolted to it is made of iron, all that is necessary for fixing is to bolt it to the flange of the pile. For wooden posts an iron socket must be used specially adapted for the purpose into which the wooden post is driven and screwed. These piles may be adapted to numerous purposes, such as telegraph poles, signal posts, flag staffs, tent poles, scaffolding, fencing, lamp posts and the like.

**SPENCE'S METAL.**—This metal compound, having a variety of advantages in non-liability to oxidation, cheapness, etc., is of especial utility to builders, and is described in the *Building and Engineering Times*: It will very probably be long entirely superseded for packing and cementing purposes. This metal fuses at a very low temperature, and can be melted in an iron pot or kettle over an ordinary fire in a few minutes. It is advisable that such a pot or kettle should be a closed one, as the metal, being a compound of sulphur, is liable to catch fire if due precautions are not taken. When heated to the proper temperature of first fluidity, the metal may be poured with ease, and need for the cementing hermetically of pipe joints, the setting of iron railings into stone, and for similar purposes. A great advantage this metal has is that it expands at the moment of solidification, and thus entirely and hermetically fills any recess into which it may be poured. This property of high expansibility at the moment of solidification renders it of great value for obtaining sharp impressions from intricate molds, and the most perfect casts of busts, statues, medals, has reliefs, etc., are thereby obtained in it. It may be colored to resemble bronzes, and consequently produces a most artistic effect. It is recommended also for repairing and even covering roofs instead of asphalt or lead flashing, as it is perfectly waterproof and water-tight and very light. It is not liable to oxidation or corrosion in the least degree, and may therefore be extensively adapted to the lining of tanks and the making of acid bottles, etc.

**GAMGEE'S MOTOR.**—Prof. Gamgee's "zero motor" has been exciting considerable attention at Washington, and scientific men are inclined to set a high estimate on its value. One of the examiners in the Patent Office tells us he regards it as the most important patent since telephone. If it succeeds at all, however, it will be of far greater consequence than that of any invention of recent times. Briefly stated it is designed to utilize the expansive force of ammonia gas as a motive power. In Chief Engineer Isherwood's report on the subject to Secretary Hunt, a document which has called particular attention to the invention, he declares the plan as devised by Prof. Gamgee as "far from chimerical." It is based on well-demonstrated thermo-dynamical principles. The whole is definite and precise, both in theory and mechanical detail, nor can it be shown, *a priori*, that there is not a fair prospect for success. The motive power, practically, being water as against coal, it is needless to say the new engine, if found practicable on experiment, must work a revolution in mechanics, superseding the steam engine, as that has taken the place of less economical mechanical powers. Prof. Gamgee is sanguine of complete success, and from his standpoint of prophetic vision, steamship and railroad companies and manufacturers are menaced with a rival more portentous than hangs over the gas monopolies; for the new force is the foe to all monopoly. —*Coal Trade Journal*.

**PULVERIZED COAL.**—The experiments of the Alexander Steamship Company in burning pulverized coal, or culm, continue to be very satisfactory, and are regarded as promising entire success. They will persevere until they feel warranted in introducing the process on board their steamers. The experiments, as we are informed, are directed chiefly to two points; one relates to this construction and position of the retort or lining of the furnace; the other, to the force of the blast used in atomizing the coal. When the latter is rightly graduated, there are neither ashes nor smokes. If it is not strong enough, a part of the coal dust falls unconsumed.

**A RACE AT NAIL FEEDING.**—The *Wheeling News Letter* of April 3d says: This nail-cutting contest between the Belmont and Top mill factories came off last week and resulted in a victory for the latter. At the Top mill the total amount of nails cut was 7,061 kegs. The men worked 11 hours each day and 110 nail machines were employed, several of which, however, were idle at times during the week. The largest previous output of the factory in one week was 6,876 kegs, working on the 12-hour system. The following will show that the boys put in their time to advantage: Bernard Bart, on 30d., cut 265 kegs; James Kenney, 20d., 222 kegs; Thomas Tagg, 8d., 85 kegs; Robert Ditty, 12d., 125 kegs; Joseph Siple, 10d., 113 kegs; Daniel Crimble, 6d., 53 kegs. Each of these is said to be above the best week's work ever done before in the city on the same grade of nails on the 11-hour system. The Belmont feeders enter a decided protest against any statement which engaged them in a contest last week. They say they only worked along as usual, without notice or knowledge of the extraordinary efforts being put forth by their would-be contestants. The exact number of kegs turned out by the Belmont was not learned, but it is known to be several hundred less than the number made at the Top. One of the Belmont attaches informed the reporter yesterday that their factory turned out on an average, over 6,000 kegs of "good nails" a week when running full, and claimed that this was a better showing than that of any other establishment of equal facilities in the city.

**FREAKS OF CASTINGS.**—Castings, says a contemporary, seem to manifest peculiar freaks and irregularities for which it is difficult to find a cause. They occur sometimes in the sand, sometimes in the venting, and often with wrong facings. For instance, the quality of facing sand must always be graded, according to the casting to be made, heavy or light, deep or shallow in the mold. Again, inferior coal in facing sands is detrimental. Possibly the dealer in foundry facings has been grinding inferior stock, instead of getting a carbon in the form of coal dust to stand the iron pouring against the mold. There has been dirt and elate ground in with the coal. This is a cause of scabby castings, together with too fine a sand or a sand without a body, which all molders dread except for very light work. If molders could only have good sands, good irons and good facings, and the same stock supplied each time, there would be little need of complaint; but the geology of our country is not such as to admit of digging molding sand at every back door, when molding sand costs from \$40 to \$50 a car delivered in a foundry yard, as we know it does in many instances.

**INCREASING THE TENACITY OF IRON.**—*La Charbon* says that M. Leguin, of Paris, has patented a process for increasing the resisting power of iron goods to tension bending, or torsion, by immersing them wholly or partly in hot diluted sulphuric or hydrochloric acids, or in a mixture of one part of turpentine in five or six parts of water. In the acid process, the metal is raised to cherry red heat, and then dipped in a solution of equal parts, by volume, of sulphuric acid of 66° strength, and of water. In this turpentine method, the mixture must be kept constantly stirred, lest the spirit should float upon the surface and take fire, on the introduction of the glowing metal. In either process, the metal is held in the solution till it has sunk to the temperature of the latter, and is then quickly thrown into cold water. The various implements, such as hooks, levers, beams, etc., subjected to this process, need only be partially immersed in the solution, the portions selected for treatment in each case being, of course, those which will necessarily be subjected to the greatest strain when in actual use.

**A MECHANICAL TRAIN ENUNCIATOR.**—A new device, the invention of a Canadian named Chasse, which, it is thought, will attract attention in railroad circles, consists in a new mechanical train enunciator. A common wire is stretched the length of the track, a little on one side of it, and a short distance above this cab. This wire is swept by a metallic fan while the train is in motion, thus keeping up a communication along the line. In each cab are a gong and a dry battery with a ground wire running to the axles of the locomotive, while at the distances of every mile the rails are grounded with a ground wire. In every depot are two gongs, which automatically ring when a train approaches within three miles in either direction. Two trains approaching each other also break the circuit, causing the bells in each cab to ring an alarm. A recent trial of the device at Chillicothe, Ohio, was very successful, and elicited the favorable verdict of the railway officials present. A practical and reliable mechanism of this character must add very materially to the security of railway travel.

The capacity of the steel works of the world at the present time is estimated at about 3,000,000 tons per year. The Bessemer works of the United Kingdom with 120 converters contribute to this total from 750,000 to 800,000 tons; the United States, with probably half as many converters, but said to be superior plant and management, produce 750,000 tons or more. Germany has lately increased her capacity for steel production, and at present can produce about 500,000. France produces 275,000; Belgium, 150,000; Austria, 250,000; and Sweden and Russia about 150,000.

## SCIENTIFIC PROGRESS.

## Eucalyptus Leaves and the Atmosphere.

H. N. Dreper writes for *Chambers' Journal* an article concerning the eucalyptus in the Roman Campagna. We take therefrom two paragraphs which will interest growers of the tree everywhere, both in showing how rapidly the trees exhaust moisture from the soil, and the influence of the leaf-exhalations upon the atmosphere:

The question of how and why the eucalyptus exercise sanitary changes so important as those which have been effected at this little oasis in the Campagna, may be best answered when two remarkable properties which characterize many of the species have been shortly considered. The first of these is the enormous quantity of water which the plant can absorb from the soil. It has been demonstrated that a square meter—which may roughly be taken as equal to a square yard—of the *Eucalyptus globulus* will exhalate into the atmosphere, during 12 hours, four pints of water. Now as this square meter of leaves—of course the calculation includes both surfaces—weighs two and three-quarter pounds, it will be easily seen that any given weight of eucalyptus leaves can transfer from the soil to the atmosphere nearly twice that weight of water. M. Valles does not hesitate to say that under the full breeze and sunshine—which could necessarily form no factor in such accurate experiments as those conducted by him—the evaporation of water would be equal to four or five times the weight of the leaves. One ceases to wonder at these figures, on learning that it has been found possible to count, on a square millimeter of the under surface of a single leaf of *Eucalyptus globulus*, no less than 350 stomata, or breathing-pores. And it now begins to be intelligible that, if such an enormous quantity of water can be transferred from earth to air, it may be possible that an atmosphere, which without such aid would be laden with malarious exhalations, may be rendered pure by this process of leaf distillation; the putrescent constituents of the stagnant water are absorbed by the roots, and become part of the vegetable tissue of the tree.

But this is not all. Like those of pine, the leaves of all species of eucalyptus secrete large quantities of an aromatic essential oil. It has recently been shown—and this statement has been impressively put by Mr. Kingzett—that under the combined action of air and moisture, oils of the turpentine class are rapidly oxidized, and that, as a result of this oxidation, large quantities of peroxide of hydrogen are produced. Now, peroxide of hydrogen is—being itself one of the most potent oxidizers known—a very active disinfectant; and as the leaves of some species of eucalyptus contain in each 100 lbs. from three to six lbs. of essential oil, we can hardly avoid the conclusion that the oxygen-carrying property of the oil is an important element in malaria-destroying power of the genus. Moreover, the oxidation of the oil is attended by the formation of large quantities of substances analogous in their properties to camphor, and the reputation of camphor as an hygienic agent seems sufficiently well founded to allow us to admit at least the possibility of these bodies playing some part in so beneficent a scheme.

**THE OCEAN LEVEL.**—M. H. Trautschild, of Moscow, lately sent in a paper to the Geological Society of France, maintaining that the level of the ocean was not invariable, in which he expressed the following conclusions: 1. The level of the sea has fallen, as parts of the earth's crust have risen from the bottom above its surface. 2. The surface of nearly all the continents has once been at the bottom of the sea, and has risen from the waters, partly in consequence of upheavals, partly in consequence of the retreat of the ocean. 3. When the continents have been formed, a part of the waters of the sea is carried away from them, and held on the land as lakes, rivers, eternal snows and as a constituent of organic matter—thus the quantity of water in the ocean has been constantly diminished, and its level has fallen. 4. As the earth cools, ice accumulates near the poles and on the mountains, water is soaked down more deeply into the crust of the earth, and mineral hydrates are formed everywhere. It follows that the level of the sea has been gradually falling ever since water has existed as a liquid upon the earth.

**THE DISCOVERY OF URANUS.**—One hundred years ago, the 13th of March, 1781, in the garden of a small house in Bath, England, an amateur astronomer was, by the means of a 20-ft. reflecting telescope, hard at work on his catalogue of stars in the constellation Gemini. His attention was attracted to one he had never seen before and not registered. Quickly applying a high magnifying power to the mysterious visitor from parts unknown, it presented a sensible disk, and proof was soon found that it changed its place among the fixed stars. The astronomer was Herschel; the unknown star was Uranus. Plain Mr. Herschel of Bath, the musician-astronomer, became famous, and honours clustered around him during his peaceful life, till in his 84th year he joined the majority.

**BEEGERITE, A NEW MINERAL.**—Prof. George A. Koenig describes, under this name, a new metallic mineral occurring at the Baltic lodes of the Geneva mining company, in Park county, Colorado. It is a sulphide of lead, copper and bismuth, having the composition (Pb Cu)₂ Bi₂ S₃, and is therefore related to the minerals cosalite and schirmerite, described by Dr. F. A. Genth from American localities. The following characteristics describe the new mineral, beegerite: The mineral occurs massive and crystalline; in the former condition it is light gray, and in the latter dark gray in color, and with strong metallic luster. This crystallization is isometric, with orthorhombic habitus. The crystals are mostly small, but as one was large enough to be measured, the cosmetic symmetry was fully established. The prevailing combination appears to be the cube with octohedron; cleavage cubical, eminent; specific gravity=7.273. Dissolve slowly in cold concentrated hydrochloric acid, but rapidly when heated. The same author describes a new locality for jarosite, in Chaffee county, Colorado, and states as the result of his investigation that this mineral is identical with alunite, the two being identical in form and structure, and forming, in fact, one species, in which Al³ and Fe² may enter singly or in any proportion, replacing each other.

**DISINFECTION OF SHIPS.**—San Francisco is, like most seaport towns, particularly liable to small-pox epidemics. It is, in fact, in a worse condition in this respect than most cities, since it is here that the Chinese immigrants first touch our shores. Our quarantine laws, though good in themselves, are not always administered so much to the satisfaction of the citizens as to the passengers on the steamers. The steamers are disinfected, or supposed to be, as soon as the passengers leave, for they must be ready for the return trip in a few days. In this connection it will be a matter of interest to know the system of disinfection for ships adopted by the medical experts of the Australian government, which we take from the *Scientific American*. It is as follows: Sulphur to the extent of 12 grains per cubic meter of the space to be disinfected was first burned in an earthenware vessel or basin, placed in the center of a mass of sand to prevent all risk of fire; every article of clothing, all the linen, etc., were hung across the cabin, the latter being then hermetically closed for three hours, and afterward exposed to the strongest possible drafts of air for 12 hours; finally, the walls, floor, ceiling, etc., were washed with one kilogramme of lime, or one-half kilogramme of chloride of zinc, to every hundred litre of water.

**PYRAMIDAL SECRETS.**—A Cairo (Egypt) despatch of May 3d says: "Maspero has just opened some more pyramids of the Sakkaro, enclosing the tombs of the kings of the fifth dynasty. The mortuary chapels of each contain about 60 square meters of the smallest and most closely written texts, giving precise details of the religious belief of that age. It is a complete *coup de grace* to the Ostris Masmic theory, and all previous conceptions are entirely upset. Except the finding of the Rosetta stone in 1799, no discovery in Egypt equals this in scientific value. The entrance passage is difficult and dangerous on account of the loose blocks that encumber it. An American Egyptologist and a correspondent are the only persons allowed to visit the interior with Maspero. The latter explorer returns to Paris next month, and will publish the discovered texts. All the Sakkaro pyramids, about 60 in number, will be opened as soon as possible.

**INTERESTING ARCHAEOLOGICAL DISCOVERY.**—A recent freshet of the Coosa river, Georgia, washed away the surface soil from a large tract of land. After the water had subsided the washed land was found to be an ancient battlefield and burying ground. Part of the territory consisted of mounds, evidently fortifications. These were strewn with implements of aboriginal warfare, beads and earthen vessels. The remainder of the ground was covered with skeletons, all perfectly exposed, and all in good preservation. A press dispatch from Rome, Ga., dated April 2d, says: "This place is attracting crowds from all directions, and it is almost impossible to prevent vandalism from seriously impairing what will undoubtedly prove to be one of the richest 'finds' ever made on the American continent. Among the countless number of Indian pipes found, is one of great size and exceedingly fine workmanship, the bowl of which is carved with great skill into the form of a human head."

**PHOTOGRAPHING A LIGHTNING FLASH.**—A very distinct photograph of a lightning flash was taken by Mr. Crowe, of Liverpool, during the severe thunder storm which visited that city on July 17, 1880. The flash, which has been made to photograph itself by its own light, appeared over St. Philomen's church at this instant the bell tower was shattered to pieces. It exactly resembles the zigzag spark of an induction coil, and is estimated to have been about 51 inches broad.

**A CURIOUS INSTANCE OF THE DEODORIZING OF ILLUMINATING GAS** was cited by Prof. Renson in a recent lecture on "Coal Gas." In Dresden a quantity of gas escaped from a pipe outside of a dwelling and passed through the earth into the house, with its odor entirely gone. It was breathed unconsciously, and several deaths occurred in consequence.

## MINING SUMMARY.

CALIFORNIA

**NYO.**  
**BEVERIDGE MATTERS.**—Inyo *Independent*, May 7: The Mexican owners, comprising the Keynote Co., have just effected arrangements to have their ore reduced at T.

tal stock, \$10,000,000. Directors—George Schultz, W. C. Walker, Henry Mill, Jesse W. Brown, Wallace King

**MEARIMAC M. Co.**—May 11. Location, California. Capital stock, \$10,000,000. Directors—George Schultz, W. C. Walker, Henry Mill, Jesse W. Brown, Wallace King.

IN northern Sonoma work progresses at the Mount Jackson quicksilver mine, and E. G. Hall is now engaged in refitting the furnace. The new Burleigh steam drill works well, doing the work which formerly required several men. The Great Eastern mine is about free from water again, and is prospering as usual.

tal stock, \$10,000,000. Directors—George Schultz, W. C. Walker, Henry Mill, Jesse W. Brown, Wallace King.

## An Important Mining Decision.

### The Richmond-Albion Suits.

The following is the text of the decision filed in the Richmond-Albion suits: Sixth District Court—Richmond Co., of Nevada vs. Albion Con. Co.; Richmond Co. vs. Albion Co.; E. H. Rose *et al.* vs. Richmond Co., of Nevada. The cases were heard upon rules to show cause for an injunction *pendente lite* between the respective parties, and for the purposes of the decision were consolidated. The property in controversy is situated upon Ruby hill, Eureka mining district, and is a limestone formation, containing well-defined boundaries of quartzite and shale. The ore bodies are found by crosscutting in the limestone from wall to wall, at varied and uncertain distances from each other. In the case of the Eureka Con. Co. vs. the Richmond Co., the character and nature of this mining ground was determined by the Circuit Court to be a vein or ledge within the meaning of the Act of Congress of 1872. The United States Supreme Court has recently affirmed this decision.

The testimony introduced upon the hearing of these cases before me established the same state of facts. Therefore, the ruling of the Circuit Court upon this issue is followed and adopted. The Richmond company claim the disputed ground by virtue of the Virginia and Poor Man locations, the St. George patent, and several other claims, but which are subordinate to the Uncle Sam. The Albion company bases its ownership to the same premises upon the Uncle Sam location which it owns. The cases were so ably and thoroughly tried and presented to the court by the learned counsel engaged, that I deem it unnecessary to express my opinion, though I shall do so as concisely as possible as to the merits of some of the asserted rights. The Richmond Co. is the owner of the Tip-Top patented claim, which is the northerly one of the series of claims owned by the Richmond. It was a seriously contested point where the westerly or northerly end of the Tip-Top should be established, the Richmond claiming it to be the line as defined in the patent, the Albion contending that the Tip-Top location was originally made and the stakes placed at positions 12 ft. southerly from the patent line. As announced during the trial, the westerly or northwesterly course as described in the Tip-Top patent will be adopted and fixed as the extreme limit of the Richmond Co.'s ground, horizontally and vertically, and as the line which must control as applying to the injunction to be issued. Northwesterly from this line lies the ground in contention. The Virginia is a prior location to the Uncle Sam, having been made about December, 1869. The Richmond Co. claims that this location contains 1,400 ft. in length, and to extend 298 ft. over and upon the disputed territory; that the notice of location was placed at what was called the iron shaft, running northerly, while the Albion insisted and proved the fact that the Virginia location was made only to cover any vacant ground that there might be between the Lookout and Richmond claims, and was of the length only of those claims.

### The Virginia Notice of Location

Calls for the Mayflower as one boundary and the Champion as the other. The Champion lies to the southerly and the Mayflower to the northerly of the Richmond and Lookout locations. The boundaries are called for in the notice will control the limits and extent of the claims, especially when the testimony as to where the location was really made is conflicting. From that and other testimony adduced upon the question, I conclude that the Virginia claim, as located, does not include or embrace any of the ground in controversy, and that the Richmond company has no right or claim to any part of this property by reason of the Virginia claim. The Poor Man was located in 1869, and is a claim nearly at right angles with the other locations, and its side lines would become the end lines. The Poor Man covers only a portion of the ground, but so far as appears its boundaries were never defined or fixed. Some work was done upon the claim until 1874. Among other serious and fatal objections urged against the validity or vitality of the claim is the one that upon the application for a patent having been made which affected the Poor Man ground, the

### Poor Man Co. Having Failed to Protest,

It resulted that any adverse right claimed by the Poor Man company would thereby be forfeited. The Uncle Sam was located January 14, 1872, by Rose and two other associates. The claim was made for 800 ft. on the ledge by 200 ft. wide. The act of Congress of 1866 gave to each locator 200 ft. on the vein, and an additional claim of 200 ft. for discovery. The location having been made for 800 ft., it is contended by the Richmond company that it is invalid, because 200 ft. of ground was taken in excess of that allowed by law. It was shown that Rose did work on this ground some six months before the location was made, and discovered what he claimed to be a ledge. He considered it a discovery. Subsequently he made this location for 800 ft., claiming the additional 200 ft. for the discovery, although the notice itself does not so mention. The evidence admitted was competent and sufficient to satisfactorily explain why 800 ft. instead of 600 ft. had been appropriated, the fact established being that the additional 200 ft. was for discovery, and I am aware of no rule of law which would require that fact to be stated in the notice or operate as a forfeiture of the location if not done. The proof is ample to sustain the validity of the Uncle Sam location for 800 ft.

by 200 ft. wide. It was insisted that the Uncle Sam company had claimed

### Different Lines for their Claim at Different Periods.

Upon making the location, Rose selected the place where he had first done his prospecting, a small hole, then in the center of his claim. After the location, he commenced a shaft at this point, and the work done on the claim afterward was in sinking this shaft to a considerable depth, which is called the Uncle Sam shaft. This is a known point, a prominent object, and being the initial point, must govern in defining the proper limits of the claim. The ground which the Albion company is entitled to possess by virtue of the Uncle Sam location is that taking this shaft at the center and extending therefrom with the ledge 400 ft. each way, with a surface width of 200 ft. The St. George claim was located in 1872, subsequent to the Uncle Sam, and occasions the material conflict in the case. The St. George company applied for a patent, to which application the Uncle Sam company protested. It is urged that the protest filed by the Uncle Sam owners is fatally defective. I have carefully examined the objections made to the protest, and have been unable to find any material omission or departure from the requirements of law which would vitiate it. The affidavit of the claimants, accompanied by the diagram of the ground, sufficiently manifested the nature and extent of the conflict. I am convinced that the protest, in all essential particulars substantially conforms to

### The Requirements

Of the law, and is perfectly available for the purposes intended. Rose *et al.*, the protestants, in October, 1873, commenced the action above, entitled Rose *et al.* vs. Richmond Co., averring title to the Uncle Sam ground. Issue was joined by the defendants in the case pleading the St. George location. The case was placed once upon the trial calendar and continued at the request of the Richmond Co. It was proven that some time in the spring of 1874 Mr. Corrigan, President of the Richmond Co., while upon a visit to Eureka, represented to Rose, and Rose to his attorneys that the Richmond Co. did not desire any litigation with him in regard to the Uncle Sam mining claim, that being the prior one. A tacit understanding was arrived at whereby the Richmond Co. would not interfere with the Uncle Sam ground, and litigation between them should cease. The case was not therefore, again placed upon the calendar, but remained pending, and was permitted to repose without prosecution. About October, 1876, the Richmond Co. procured from the County Clerk of Eureka county a certificate to the effect that the case had not been placed upon the calendar for trial for several terms of court, and filed this with the Receiver and Register, who thereupon recommended that a patent issue to the Richmond Co. for the St. George mine. Upon this the Commissioner of the Land Department decided that the case had

Not Been Prosecuted With Such Diligence As the act of Congress requires, and issued the St. George patent May 7, 1877. The important question presented is whether the Albion Con. Co. can assail this patent in this case by way of an equitable defence, or whether a direct proceeding must be resorted to to cancel the patent. The action of the Richmond Co. vs. the Albion Con. Co. is in the form of ejectment to recover this ground, relying upon the St. George patent as title. The Albion Co. has fully answered, setting up the claimed equities, and asking that the Richmond Co. be decreed to hold the St. George patent in trust. Under the code of this State, law and equity are blended, and the defendant may avail himself by answer of as many defences as exist. The Richmond Co. is seeking to recover this property from the Albion by force of this patent. It is the muniment of title, and I can discover no sufficient reason, upon principle or authority, for denying the defendant the right to assail this patent in this action for the same causes and upon the same grounds that it would assign originally to a Court of Equity to obtain the same relief. I cannot conceive of any forcible or tangible objection that can be opposed to this proceeding, the State having full jurisdiction.

### To Afford Equitable Relief

In all properly presented cases. The United States Supreme Court has sanctioned this right and practice in several cases. I therefore conclude that the Albion Con. company, being the equitable owners of the Uncle Sam ground covered by the St. George patent, is not compelled to resort originally to a court of equity, but that it can obtain the desired relief from the effects of the patent in this action upon the trial of this case. The succeeding question is, Did the commissioner exceed his power in determining that the suit of Rose vs. the Richmond company had not been presented with diligence? Upon this question there can be no doubt. The act of Congress provides that when a protest is filed to an application for a patent, that the party protesting shall commence an action in the State court to determine the contest, and that thereupon all proceedings shall be stayed in the Land Office. Upon the commencement of this action, the Land Department is divested of all further jurisdiction of the subject matter until the court shall have finally determined the controversy between the parties. The court acquires and possesses the exclusive jurisdiction of the entire matter. The question of whether the action is prosecuted with diligence is one for the court to

decide, and not the commissioner. To hold otherwise would be to allow the commissioner at all times to deprive the court of its jurisdiction and of determining questions which the court alone has the right and power to adjudicate. I must pronounce the action of the commissioner, in deciding that the Rose case had not been prosecuted with diligence, as wholly without power, and his act of issuing the St. George patent while the action was still pending in courts undetermined as lawful, entirely without jurisdiction or authority, and of committing a wrong which equitable interference alone can redress. From the foregoing, while it is already demonstrated that the Albion company will be decreed to be the owner of the disputed ground, and of the Uncle Sam claim, unaffected by the St. George patent, still there is no power in court upon this hearing to grant the relief which it is so assuredly entitled to, and I can only express my convictions as to what must be the evident result upon the merits. I should not hesitate to dissolve the injunction against the Albion company, except for the reason that the legal title to the Uncle Sam ground, covered by the St. George patent, stands in the name of the Richmond company; and as the Albion company can only obtain the relief which it is so eminently entitled to from the operation of this patent by decree at the trial, until that shall be accomplished I shall consider it to be my strict duty, in the endeavor and anxiety to do

### Exact Justice and Equity,

That in the meantime the rights of both parties should be scrupulously protected and the mine preserved, which is represented to be valuable. For this reason alone I am persuaded that all parties should be prohibited from invading or destroying the substance of the property. It is therefore ordered that the restraining order heretofore issued in each of the above entitled actions will be continued in full force, taking the Tip Top line, as indicated in the boundary line, until the further order of the Court. Bonds to be fixed by the District Court.

RICHARD RISING, District Judge presiding.

## Summer Resorts in Tehama County.

The celebrated Tuscan springs are located east of Red Bluff in the foothills of the Sierras. They are reached by a pleasant ride of eight miles from the Bluffs. Good accommodations are furnished by Mrs. Bradley, who is proprietress of the springs and the accompanying hotel. There are many walks and drives constructed in different directions, in such a way as to add pleasure and comfort to health seeking. The climate is very desirable, owing to the fact that the site of the springs is at just such an elevation as to give a medium temperature, somewhat removed from the heat of summer and still warm enough to be enjoyable in winter.

In the adjoining mountains and valleys are afforded the finest of opportunities for fishing and hunting, but the principal consideration is the medicinal qualities of the waters of the springs, for they strengthen for active life those who are weak and ailing, either in mind or body. In 1854 a learned scientific man, Dr. Veech, discovered that the waters of these springs possess medicinal qualities of great value. The waters are pronounced by the best chemists and most learned physicians to possess qualities equal to almost any waters in the United States. For the cure of rheumatism, dropsy, neuralgia, liver complaint, paralysis, dyspepsia, catarrh, etc., these waters are unsurpassed on the Pacific coast.

### Toome's Camp.

This is a beautiful summer resort, situated about 35 miles southwest by west of Red Bluff. Its elevation is about 5,000 ft., and consequently clear above all effects of the oppressive heat of the summer months in the valley. To this camp there is a good wagon road, comparatively easy of ascent. The sighing of the magnificent forests of evergreen, rippling of mountain streams, beauty of flowers and singing of birds, and coolness of the refreshing waters, quaffed from nature's own bosom—the graciousness of such shade and a general exhilaration through one's whole nature, causes him to feel that he is, at least for a while, entirely free from all worldly anxieties and cares, and has found what might almost be called a paradise upon earth.

This camp is frequented by from 50 to 100 persons during the summer months. In every direction from here are places of interest. South Valley Valley, 14 miles distant, is reached by a plain and easy trail leading to the northwest. On all sides of this peak may be found beautiful streams, valleys and lakes. One place is deserving of particular mention, called Solomon's Pool. It is sort of a meadow, nearly level and in a circular form, being about 200 yards across. On all sides but one it is surrounded by high walls, nearly perpendicular and rising in some places several hundred feet high. Down from the heights of the hoary sentinel, covered always with perpetual snow, come streams of the clearest and brightest water, fresh from the mighty masses of snow above. Several of these, after rippling and sparkling, dashing and tumbling, foaming and falling, and roaring, unite and form a stream of larger size which, seemingly, wearied with its exertions, gladly chooses a passage through so beautiful a valley as the one above mentioned.

While passing through Solomon's Pool, this stream slackens its course and during its passage moves along as quietly and stately as a valley stream. Soon, however, it has made the passage, and having sought the only outlet from this pleasant retreat, goes rushing on to its mother stream, the Cottonwood, which takes it after its perilous journey, and hears it still downward. There are just enough of the most beautiful evergreens near the opening of this circular valley to make a beautiful camping place. The best of grass grows luxuriantly over its whole surface; in fact the whole surroundings are such as to make this one of the most enchanting scenes I ever witnessed.

Hensley springs, and Sulphur springs are also situated in the Coast Range mountains, nearly due west of Red Bluff. Both of these claim peculiar medicinal qualities; space forbids me, however, to write concerning them. All the resorts of the Coast Range are comparatively difficult of approach, and consequently much less frequented than those of the Sierras. In Big valley and all the surrounding country, ere many pleasant resorts at which a great portion of the people of Red Bluff and the surrounding country spend a portion of the summer, camping out in the free air of heaven, and enjoying a few weeks spent in fishing and hunting, thus becoming strengthened and prepared for the arduous labors of another year of husy toil and anxiety.

The climate of the Coast Range is considered better for invalids, especially so for those who are consumptive, as the air of the Sierras is too moist and the nights too cold.

The proximity to the Pacific ocean tends to render the climate of the former more agreeable. Game is also more abundant there. For these reasons, were it not for the fact that the ascent of the Sierras is more easily accomplished, the greater portion of the health and pleasure seekers would go west instead of east.

The scenery, climate, etc., are magnificent in both mountain ranges, and, in fact, in every part of Tehama county. I will close with the following from our "County History."

### Magnificent Panorama.

There are not many other places, if any, in the United States that afford a finer or a grander view than is obtained by one standing at Red Bluff. It is a magnificent panorama of mountains and valleys; of hills and dales; of tropical groves and snowy peaks—a scene to enchant the poet's mind or to charm the worshippers of nature. Away to the right rises, in abrupt and craggy cliffs, the clear outlines of the Coast Range.

In winter they are mentled in a heavy coating of snow, whose lighter folds fall over the lower hills, where its whiteness is here and there relieved by the rich green of the forests of pine.

Five thousand feet high and 40 miles distant, in the clear air, every ridge and gully, every gap and peak are distinctly visible.

Away to the east rise in snowy grandeur the rough and rugged ridges of the Sierras. Rising gradually from the south they culminate in Lassen's Buttes, a cluster of volcanic cones which rise over 10,000 ft. above the sea. In winter they are covered deep with snow, but in summer only sufficient remains in the canyons on the northern slopes to give them a hanged appearance. In front and far away to the north, beyond the boundaries of the county, the eye wanders over the Trinity, Scott and McCloud mountains, and is almost lost in their wandering ridges.—S. A. Stiles, in *Rural Press*.

## The Growth of Pinal City.

Certain occurrences mark the growth and progress of a place, which the daily current of events do not impose upon our observation. Mr. Disturnel has been here and taken items for his new Arizona Business Directory and Gazetteer for 1891. He showed us his figures. He found in Pinal about 100 business men, exclusive of Silver King and Queen City, which, together, will make up about 150. He found about 140 in Globe, about 400 in Tucson and a few more at Tombstone. Our existence as a town, hurch, or city dates back about two years. We had scarcely an existence then. Nor can we measure ourselves as the equal of Globe, which is years our senior, and with the Pueblo Viejo itself, the ancient Tucson, for we exceed already one-third in business men numerically of that fasthold of citydom. The amount of business done at Pinal, King and Queen, for they are melting together rapidly and are now in fact one, run up into the rate of millions annually. Our immense stocks of merchandise and the activity apparent at every step tells the whole story. The road is lined with teams between Pinal and Casa Grande, and still they cannot clear the depot there of freight for Pinal. We do not wait for crops to ripen, nor for ships to come home from sea. We take thousands daily out of the earth, and scatter them over the area of business and life and enterprise. We have not only the Silver King, the richest and best paying mine in the world, but we have 100 mines around Pinal, already further developed than was the Silver King two years ago. And endless is the prospect, for the mountains all around us are hrimful of precious mineral. The immediate future of Pinal is indisputable, its future greatness is a certainty, its permanency incontrovertible.—Pinal Drill.

SWITZERLAND.—All the tunnels on the south side of the Alps are now bored, and the plecting of Tassin in direct railway communication with the rest of Switzerland is only a question of a few months.

## THE ENGINEER.

## Comparative Corrosion of Iron and Steel.

A paper was recently read before the Institute of Civil Engineers (England), by Mr. D. Phillips "On the Comparative Endurance of Iron and Mild Steel when Exposed to Corrosive Influences." The author was a member of the committee appointed by the Admiralty in June, 1874, to inquire into the cause of corrosion in boilers, and since the dissolution of the committee he had made further experiments with the same object in view. The results were given of numerous tests, the surfaces of the specimens in nearly all cases being bright. From an abstract of the paper in *Iron*, we take the following extract from that portion where the author referred to a series of experiments with iron and steel plates (crucible, Bessemer and Siemens steels, and Staffordshire and Yorkshire irons), suspended in the boilers of ocean and coast-going steam vessels belonging to various shipowners. The exposed surface of each plate was 37.89 square inches. Taking the results from 56 sets, the percentage in favor of the iron over the Bessemer and Siemens steels was 21.3. The different results obtained from some of the sets might be thus summarized:—No. 43 set was suspended in the boiler 285 days. The boiler was filled 14 times with fresh water, two inches of water being blown off daily. No. 2 set was in the boiler 311 days. The boiler was filled eight times with fresh water, and five times with sea water, three inches of water being blown off daily at sea, and 12 inches at intermediate ports. The mean loss of weight in No. 2 set was 825.4 grains, as compared with 347.7 grains in No. 43 set, or nearly two and a half times as much. Boiler 62 was filled five times with fresh water, one inch of water being blown off daily. The plates were in the boiler for 298 days. The mean loss of weight was 364.9 grains, as compared with 825.4 grains in No. 2 set. Set 84 was in the boiler 43 days, the boiler being filled four times with sea water and once with fresh water, an average of 73 inches of water being blown off daily. The mean loss of weight was 575.7 grains, as against 364.9 grains in 62 set—being at the rate per month of 30 days, of 401.78 grains in 84 set, against 367 grains in 62 set. Comparing set No. 9, which was suspended in a jet condensing boiler, with 62, which was subjected to something like the most improved method of surface-condensing treatment, the loss in No. 9 was nearly four times that in No. 62 set.

These results clearly prove the error of the conclusion arrived at by many experienced persons previous to the appointment of the Boiler Committee. Experiments made by the author with plates similar to those mentioned, placed in sea-water, in rain-water, exposed to the weather only, and exposed to the weather and dipped in sea or rain-water daily gave a result of 64.8% in favor of the iron, omitting the hard steel. The corrosion was strikingly local and severe in the set placed in rain-water. Wetting the metals daily, especially with sea-water, and exposing them to the weather, caused very severe corrosion. The results of these experiments incontestably proved, that under almost all circumstances iron, and especially the harder sorts, was far superior to steel in the resistance it offered to corrosion.

**THE TAY BRIDGE.**—We (*Glasgow Herald*) understand that the plans for the construction of the new Tay bridge are now completed. The foundation piers, which are to be in pairs, are of immense size, and will be built of brick up to a height of 8½ ft. above high water, and on the top of these the supporting columns are to be placed. They will be octagonal in form, and of malleable iron, broad at the base, and narrowing at the top. A strong iron parapet will be erected on both sides of the bridge. At the south side the double line is to start at the same level as the present bridge, but it gradually falls by a gradient of 1 in 180 towards the north shore, which it will join on a level with the Esplanade. The spans over the navigable part of the river are to be 58 ft. 6 inches in height, and will be opposite the four southmost of the 12 wide spans of the present bridge, while opposite the center of the eight other spans a new pier is to be introduced. So far as the testing of the foundation piers of the present bridge has been effected, the results have been very satisfactory. The two piers which have been tested were each laden with 1,800 tons of metal, and under this enormous weight they were found to have scarcely yielded. The new bridge will be of immense strength, and quite adequate to resist the strongest gale which may come against it.

**PROJECTED RAILWAYS AND TELEGRAPHS IN CHINA.**—Intelligence from Peking states that Prince Li has advised the construction of a railway between Tientsin and Peking. Another line between Nienkin and Shanghai is projected and also telegraphic communication.

*Heraclitus's Journal* says: "There is no country in the world so favorable to railway construction as the Argentine Republic. It is as flat as a pancake and abounds in traffic. Capital cost is low, revenue receipts are high."

TEN Chinese engineers have arrived at Stettin, with a view of learning the art of building ironclads.

## USEFUL INFORMATION.

## A New Hydro-Carbon.

The new liquid hydro-carbon, to which reference was recently made in these columns, appears to be still attracting much attention in Europe. A French journal states that at a recent meeting of the Société d'Encouragement des Arts, etc., some remarkable experiments were made with this liquid, which boils at about 100° Fahr., and is said to burn with a brilliant white flame of a comparatively feeble temperature. On the occasion in question, a large can containing a supply of the liquid was set on fire by applying a light to its mouth, the spirit was then poured while flaming into lamps. The flame, spreading on all sides, simulated the beginning of a great conflagration, but was eventually extinguished by the lightest puff of wind. Any one in need of a light, but without a lamp for properly burning this liquid, may do so by dipping the corner of a pocket-handkerchief or the finger of a glove into it; and thus may be made a temporary torch, which when blown out will be found to leave the improvised wick without the slightest injury. Lamps intended to burn this spirit are constructed in such a manner that they are extinguished if thrown down. It is said to be extremely difficult to form an explosive mixture with the vapor of the new spirit and air, and that in any case the explosion cannot be made violent. The liquid has a slight and not disagreeable odor, and is not dear. It is sold at present at eight cents per pound, and its production is said to be unlimited. It has on other occasions been said to be a product of the Galician mineral hydro-carbone.

**AMMONIA FOR PREVENTING PETROLEUM FIRES.** M. Schlumberger has communicated a note to the Société Française d'Hygiène on the "Automatic Extinction of Petroleum Fires." Many accidents are caused, he says, chiefly by the igniting of the substance through imprudence. The druggist, for instance, in going into the cellar where the oil is kept does not always take proper precaution, and the result is that a disastrous explosion often takes place. He proposes a method of extinction in this and similar cases which he recommends shall be made compulsory under police regulations. His plan is to place on each barrel of petroleum a large bottle of liquid ammonia, so that, at the least explosion or on contact with the flames, the glass will be broken and the vapor of the liberated ammonia will form an automatic mode of extinction. The author states that he speaks from practical experience, and that he has frequently been indebted to ammonia for safety while conducting distillations of a dangerous character. He suggests that the plan should be extended to mining operations, and that easily broken vessels filled with ammonia should be stored wherever there may be a risk of accident from fire-damp explosions. Carbonic oxide cannot burn in an ammoniacal atmosphere.

**SHAFT COUPLINGS.**—There is an innate wickedness in the average shaft coupling; an inborn tendency to get loose, split, ring off, stick fast, etc. It is not reasonable for any one to expect that a line of shafting will keep in good order if hung to the bottom of a springy floor. The shafting should not be put up before the floor has received some, if not all, of its load, especially if there be heavy machines above it, which, will when put up, tend to sag the floor. Where the shafting is attached to cast iron columns supporting the floor, there is less trouble from sagging, either when the first load is put on the floor, or afterward when the building settles. The banger adds nothing to the torsional resistance of the shaft which it supports. The torsional strength depends upon the length and diameter of the shaft. Some recommend that flywheels be put on long lines of shafting, as tending, in a great measure, to equalize the strain of transmission.

A CURIOUS musical instrument called a color organ has been invented. When the various notes are sounded by touching the keys, different combinations of colors are reflected upon a ground glass plate, and these change and blend in a charming manner as a quick air is played. Thus two senses are gratified at once, and the beholder feels more than he understands the harmony between melody and color.

**THE LARGEST PYRAMID.**—We believe it is not generally known that the largest known pyramid rests on American soil. The Pyramid of Pueblo, in Mexico, is larger than the great Pyramid of Cheops, in Egypt. The latter covers only fourteen acres, while the Mexican one covers forty-four acres of ground, and was originally 600 feet high. It is made of sun-dried brick, and is supposed to have been built 7,000 years ago.

**A NOVEL METHOD OF RAPID LIGHTING.**—At the Royal Palace in Berlin, 40,000 wax candles are instantaneously lighted by a single match. The wicks are previously connected by a thread spun from gun cotton, on lighting one end of which all the candles are lighted simultaneously, and thus the whole of the 700 apartments are lighted at once.

**ACID PROOF CEMENT.**—Finely powdered glass, mixed with soluble silicate of soda will be found to answer this purpose.

**GERM FOOD AND ITS MANUFACTURE.**—An Eastern firm has lately introduced an article of diet called "Universal Food," which is thus described by the *Miller's Journal*: In the manufacture of this food, those portions which the miller is so anxious to exclude as coloring the flour, the germs, are made use of. The principle on which this food is based is the introduction of a natural chemical agent into the system, which has either not developed, as in the case of the infant, or which is lacking from such cases, as in disease. This chemical agent is diastase. Diastase is one of the chief ingredients in the pancreatic juices and saliva in the healthy adult. When from any cause the system becomes diseased, the percentage of animal diastase or ferment becomes less and less, until sometimes it is entirely absent. In children under one year of age it is found very sparingly. Starch, as starch, possesses no nutritive powers; it is only when converted into sugar and dextrine that it becomes of any value to the system. The province of diastase is that of a ferment. By its action starch is reduced into its component parts of dextrine and sugar; and if this fermenting agent be absent, the starch remains unchanged and useless. If therefore through disease or insufficient development this active principle of digestion is not secreted, the production and use of a food which shall fulfill this want is to be commended. The wheat germs are ground to a flour and made into a dough. This dough is cooked at a temperature of 150° F. for 30 hours in sealed boxes. This is re-ground and put upon the market in the form of a flour.

**A STATION INDICATOR.**—Many devices have been proposed for a practical railroad station indicator; but heretofore with very little success. Recently, however, a Hartford, Conn., inventor seems to have hit upon a device which is so promising of coming into general use that a company has been organized for its manufacture. It is described as follows: An ornamental box contains a roll of lettered canvas or other material, giving a list of the stations in their order, and over the opening where they are exhibited is printed "The next station is." By successively turning the roll of canvas the stations appear in due order, and at each change by a clever contrivance a shrill little whistle is blown for a moment, thus attracting the attention of all persons in the car. The whole thing is worked automatically by compressed air, and is all controlled by the engineer.

**IMPROVED EMERY WHEELS.**—An improvement in the manufacture of emery wheels consists in bedding within the wheel one or more disks of woven wire, which extend from the center nearly to the periphery.

## GOOD HEALTH.

## Healthy Women.

(Written for the PRESS by MRS. E. J. S.)

Woman's incapacity is the only real barrier to her progress. Whenever women will show themselves able, men will be compelled into willingness. They need, strength, caliber; they do not value enough muscular power. Aesthetic young ladies have imbibed and propagated the idea that feebleness and fragility are womanly and fascinating. The result is a legion of languid headaches, an interesting inability to walk half a dozen consecutive miles, a delicate horror of open windows, northwest winds and wholesome rain storms. There is no computing the amount of charming invalidism following in the wake of such a line as

"There's sweetness in woman's decay."

I do not refer to real invalids, who have inherited feeble constitutions, and by unavoidable and often unselfish and unceasing wear and tear, have exhausted their small capital, and to whom life has become one long scene of weariness and pain. Heaven help them bear the burden; and they do often bear it nobly, frequently accomplishing what ought to make their robust sisters blush for shame at their own inefficiency.

I mean women who have every opportunity to be healthy, but are not so, who are sick when they should be well. A woman of 20, in comfortable circumstances, ought to be as much ashamed of being dyspeptic as of being drunk. Fathers and mothers, hardened with cares and anxieties, may neglect physiological laws without impugning their character, but for a girl, carefree, to confess such an impeshment, is presumptive evidence of gluttony, laziness, or ignorance, and generally all three. I do not use elegant language I know; but let us call things by their right names, thinking we may better impress the indisputable fact, that a great majority of ailments arise from over-eating and under-exercising. The innumerable hosts of nervous diseases with which our women are afflicted are always aggravated, and often caused by these indulgences. Very few women know this, and if they did, it would be of little use so long as they considered illness one of the charms of beauty. If women could think that a good digestion is as excellent a thing for them to possess as for men we could soon make a change; and it seems to me a very queer taste to like sick and complaining women.

"I have finished my education" are words often said by young ladies fresh from boarding school; these restricted ideas of education have been so strongly impressed upon her mind that she feels content and satisfied to hang up her framed diplomas and use the smattering that superficial instruction affords her. We might as well expect to raise giant oaks or imperial cedars in flower pots as to expect noble lives with such stunted notions of education.

The public sentiment is grossly at fault on the subject of the physical education of females. In childhood girls should be as hardy and capable of enduring fatigue as boys, because nature has kindly endowed them with equal constitutional power to perform the duties of life; but when they are matured why are men healthier than women? Look at the families of merchants and business men. The men are active, industrious, accustomed to bodily exertion. Busy all day with sales and boxes, driving about the streets and wharves and looking after their affairs, their minds and bodies fully employed, they go home with a keen appetite; while their wives and daughters have dragged through the long day in listless idleness of sedentary pursuits, and they approach the table without an appetite, spurning the repast other hands have prepared, and, in answer to inquiries as to health, they fill the anxious husband's or father's ears with complaints of a thousand ills, to obviate which large doctors' bills and expensive trips to westerling places are incurred with no permanent benefit. Poor creatures, they have not been properly educated. The culture of the body has been neglected.

Women are as good as men—Nature has not said they are better—and they have a right to all the advantages which good health affords, and to all the means of obtaining it in a natural way. If work is the parent of health, let us not consign our girls to music, drawing and ornamental needle-work; let them harden their hands, brown their faces by sun and wind, no matter if fashion would toss its brainless head because they are not slim, pale, delicate, with soft white hands. Women do not lack reasoning power, and they can be developed as calm, earnest, common-sense companions, counselors and helpmeets for men; and who needs wisdom, judgment, reflection and a well-disciplined intellect, combined with strong affection and elegant refinement of taste and feeling, so much as she who is to mold the character of a family which is to control the church, the State and the business world of the next generation? Let them be taught chemistry, for they must compound the food of the world, and thereby obviate the necessity of the compounding of drugs at all. Let them study physiology, for they have charge of the clothing, feeding and health of the world.

Why should a woman be a life-time learning the laws that govern health, and only learn by sad experience how to conduct the physical and moral management of the young when she has grandchildren to exercise that knowledge upon? Knowledge is better late than never, but don't defer it until a generation of mental and physical constitutions are ruined, and half a generation are made tenants of short graves. Who more than a woman needs all the stores of solid learning and thought to manage a family and fill her station in life with wisdom and dignity? Give her a whole education and she will cease to be deemed a frivolous, fitful, useless butterfly. It is a wonder her education has not spoiled her. If she was not the better half of creation she could not have endured so much bad management, and still be worthy of adoration by the other half.

Within the last quarter of a century female education has received new attention and made vast progress, and we know that educated women will hereafter be companions for educated men and mothers of coming generations, and we await with patience the time when the errors of female education, as it relates to the body, will be corrected, and our women will have, as a rule, red cheeks, full chests, stout muscles, energy of action, fine health and a good appetite, and therefore never be the dependent, dissatisfied being we sometimes bear of now.

Calistoga, Napa Co., Cal.

**TREATMENT FOR A FELON.**—Take of soft lye soap and flaxseed-meal, or corn-meal, a sufficient quantity, stirring the meal in slowly and thoroughly, so as to form a salve or poultice. Envelope the finger in this, applying snugly, to bring it in close contact. Renew the poultice every 12 to 24 hours. Don't try every prescription you may hear of. Depend on this. It will, if applied in time, absorb the disease; if adopted later, it will bring it to a small "head" (if too far advanced to be "scattered") when it may be picked almost painlessly.—*Therapeutic Gazette.*

**THE LEMON VERBENA.**—The well-known lemon verbena is systematically gathered in Spain, where it is regarded as a fine stomachic and cordial, used in the form of a decoction. It is said that if it be used one need never suffer from flatulence, nervousness, diarrhoea or loss of appetite.

**ICE WATER AND BRIGHT'S DISEASE.**—The idea has recently been advanced that Bright's disease is attributed to the immoderate use of ice water. The fact is cited that the people of this country use 90% more ice in their drink than the people of any other country—Greenland not excepted.

## TABLE OF CONTENTS.

GENERAL EDITORIALS.—Emery Wheels; Re-locations and Expenditures; The Railroad Commission, 305. Passing Events; A Drill Sharpener; Mining Partners and Re-locations; Artesian Water in Oakland, 312. The Walrus, 313. Notices of Recent Patents, 316.

ILLUSTRATIONS.—The Tanito Co.'s Reversible Rest, Single-Wheel Grinder, 305; Drill Sharpener, 313; The Walrus, 313.

MISCELLANEOUS.—Copper Smelting—Its History and Processes—No. 2; The Cost of Milling Ores in Utah and Nevada—No. 3; Gathering Eucalyptus Seed, 308. An Important Mining Decision; Summer Resorts in Tehama County; The Growth of Pinal City, 310.

MECHANICAL PROGRESS.—Driving Tuhular Piles; Spence's Metal; Gangee's Motor; A Race at Nail Feeding; Freaks at Castings; Increasing the Tenacity of Iron; A Mechanical Train Indicator, 307.

SCIENTIFIC PROGRESS.—Eucalyptus Leaves and the Atmosphere; The Ocean Level; The Discovery of Uranus; Begerite, a New Mineral; Disinfection of Ships; Pyramidal Secrets; Interesting Archaeological Discovery, 307.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments, Meetings and Dividends, 308.

MINING SUMMARY.—The various counties of California, Nevada, Arizona, Idaho, New Mexico, Oregon, and Utah, 308-9.

THE ENGINEER.—Comparative Corrosion of Iron and Steel; The Tay Bridge, 311.

USEFUL INFORMATION.—A New Hydro-Carbon; Ammonia for preventing Petroleum Fires; Shaft Couplings; Orem Food and Its Manufacture; A Station Indicator, 311.

GOOD HEALTH.—Healthy Women; Treatment for Folio; The Lemon Verbena; Ice Water and Bright's Disease, 311.

Extra Dividend Notice—Northern Belle M. & M. Co.

## Passing Events.

The Wood River fever continues unabated. Various reports come from there. Those who have not found bonanzas the day of arrival write back that it is a dead failure. Those who have gone determined to work appear to be favorably impressed. The next few months will tell the tale better than we can tell it now.

One man says he would not advise anybody to come at present in the hope of getting work, but for prospectors the country is good and they cannot come too soon.

We hear of a good many strikes in California mines of late. That at the Rawhide, in Tuolumne county, is a very encouraging one.

The southern part of the State, particularly San Bernardino county, is coming to the front rapidly as a good mining country.

Another event of hardly less significance to the general prosperity, is that the Governor has given the Legislature notice that if they linger longer at the capital they must do it at their own and not at the public expense. The law makers were called together for certain necessary deeds, but quickly lost sight of them and fell into a maze of selfish interests and political plots that there seemed no certainty of anything except the *per diem* of members. In the rough old times the executive power would have driven the useless law makers from their seats. Modern constitutions and laws make such proceedings nowadays impossible, but there is still a way, and the Governor has found it. The vulnerable point is the pocket. The people should be thankful that there is this joint in the harness.

An old mining camp, with an abundance of rich gold ore, has been discovered in the Ticolina mountains, 15 miles from Las Vegas, N. M., at an altitude of 10,000 ft. Crude utensils for extracting and crushing the ore were found strewn about the place.

## Mining Partners and Re-locations.

The acting commissioner of the General Land Office has decided a question which is of very great importance to miners. He says, in effect that where a lode mining claim has been located by several persons jointly, and thereafter the required expenditures have not been made, the claim may be re-located by one of the former claimants to the exclusion of co-claimants.

Now this is a ruling which has a very important effect. It not only gives an honest miner a chance to rid himself of profitless associates, who won't come up with their share, but it also gives a chance for dishonest miners to get rid of partners, in ventures likely to be profitable, if said dishonest men are in charge of the property. People who have invested in claims with others, may as well look sharp personally, that this work is being done.

The question on which this ruling was made came up in the following form: "Can one of the locators of a mining claim, upon which the necessary amount of expenditures for a given year have not been made, re-locate the same as abandoned property, in his own name and for himself only?" The Acting Commissioner answers: "Section 2324, Revised Statutes, after prescribing this value of labor to be performed, or improvements to be made annually upon each claim, in order to protect the possessory right of locators, provides that 'upon a failure to comply with these conditions the claim or mine upon which such failure occurred shall be open to re-location in the same manner as if no location of the same had ever been made; provided that the original locators, their heirs, assigns or legal representatives, have not resumed work upon the claim after failure and before such location.'"

"From this it will be seen that the only question to be considered in the case stated is whether one of a number of original locators, whose claim has been abandoned, would stand upon the same footing as a stranger to the first location, who, by the provision above recited, is expressly authorized to re-locate such abandoned claim.

"It is clear that one of a number of locators of a certain claim can, concurrently with such joint location, locate a separate claim, independently of his co-locators; and as an abandoned claim reverts to the mass of unappropriated public lands, and becomes subject to a new appropriation, 'in the same manner as if no location of the same had ever been made,' I can see no valid objection to a new adverse location of such claim by one of the former locators."

At the same time, the commissioner decides that labor performed or improvements made by an original locator, cannot be claimed by him as part of the expenditures necessary to entitle him to a patent for re-location.

## A Drill Sharpener.

T. J. Williamson, of Carson, Nevada, has lately devised a simple instrument for sharpen-

Mining Drill Sharpener.

ing mining drills and cold chisels, which is represented by an engraving on this page.

The blocks that carry the dies *b*, are made of iron, and hinges together by a pin, so as to divide transversely on the line between dies, to permit insertion or removal of the drill. The steel dies are held in a dovetail mortise in the upper side of the blocks, so that each is held securely. The adjacent faces of the dies are formed with recesses of a shape corresponding to the drill-points. There are three of the recesses in the dies, adapted for drills of differing sizes, so that either one of the recesses or openings may be used, according to the size of drill that is to be sharpened.

The instrument is to be used in the following described manner: The drill to be sharpened is first heated, and then the end, or point, placed between the dies *b* in the recess that corresponds to the diameter of the drill, and the blocks and dies closed upon the drill point; then, by striking a few blows with a hammer on the drill head, the point is spread and caused to take the shape of the recess and the edge sharpened.

The drill is thereby brought to the uniform size, and the angles that may be broken filled out. The drill is then removed by opening the block and dies, and hardened by plunging it in water.

This device is simple, and requires no special skill for its use. It is adapted for use at the place where a well is being drilled or holes drilled for blasting, and by the men using the tools.

By its use the drills, and consequently the drilled hole, can be kept of uniform size. Miners generally use three sizes of drills, and the instrument is constructed so that it is adapted for the three sizes used.

## Artesian Water in Oakland.

The operation of boring an artesian well is a very simple one, requiring no very complicated apparatus or expensive machinery. Yet skill is required in handling the rods and tubes, the drills and augers, and in using the proper appliances at the proper time. Sinking a shaft is an easy thing to do, but it takes a miner to do it well. So with the artesian well, any one can do it, but the man with experience can do it best.

In previous numbers of the PRESS we have given the *modus operandi* of artesian well-boring, with illustrations of the various devices used. And we have also given engravings showing the location of the wells in San Francisco, and diagrams showing the position of the water-bearing strata, from the Sierra across the Sacramento valley, under the bay, and in this city. In the present case, therefore, we shall confine our remarks to the question of artesian wells in our sister city of Oakland, where there are many.

Oakland being a large city as to area, its population being spread over a very wide tract, and all the homes having more or less ground around them, requiring more or less water, the question of water supply has been a serious one. It is pretty well conceded that the city should supply itself with water. It is the opinion of 99 citizens out of 100 that if the city had provided its own water and gas, economically, at an early day, the population would now be from 50,000 to 60,000 instead of 38,000. More cheap homes would have been built, and more manufacturing enterprises established. The citizens now want cheap water, cheap gas, cheap fuel and good wagon roads, the narrow gauge railroad tunneled through to Contra Costa county to bring in cheap produce, when Oakland will rapidly expand. The narrow gauge railroad will be a good promoter in this direction.

Now, Oaklanders cannot have all these advantages at once, but they will soon have the new railroad and they now have cheap artesian water. This is a fixed fact. The artesian water of Oakland is generally of superior quality. On the block in which the writer lives is an artesian well 84 ft. deep, and the water rises from the bottom stratum of this to within two or three feet of the surface. This water is pure, clear and sparkling, and is, moreover, very cold and palatable. This is the case with all the artesian water. There is no smell of frog-pond about it. In the filters in Oakland houses there are now bodies of loathsome worms, leeches, hogs, etc., horrible to the sight, to say nothing of the taste. And yet these things are not so nauseating as the remembrance of at least a few citizens who, not many years ago, used to see the pulpy refuse of 30 to 50 cows wheelbarrowed down to the creek in the dry season from a dairy yard and dumped in a location from which it was sure to be carried by the winter rise in the stream directly into the reservoir that still supplies a large part of Oakland with water.

We are glad to say in the cause of humanity, however, that that practice has been discontinued for years.

People who have modest homes and medium-sized families are generally required to pay as much, or more, in Oakland for water than for either the items of bread or of milk. In fact, nearly all of the citizens of that town feel as if they were robbed every time they have to pay this extraordinary monthly water rent.

In the first place, you have to pay for your water before you get it. In the next place, when you do pay for it, you get something of a very poor quality. The water people argue that the water is free; they charge nothing for the water. But they charge for delivering the water. And they don't deduct anything in winter, when they bring you almost as much mud as water, and in the fall, a very undesirable proportion of vegetable matter.

In one way, however, the Oakland people can get ahead of the water company, and that is by getting artesian water, a less costly operation generally than in San Francisco. To learn the capacity and cost and location of a number of these wells, we interviewed Mr. W. G. Spence of 604 14th street, who during the past few years has bored the following wells, and who gives us particulars from memory.

We give the approximate capacity, but in a number of instances it is doubtless understated.

No. 1 is a well of 12-inch bore, corner of Kirkham and 5th street. It has a capacity of 10,000 gallons per hour, is 180 ft. deep and was made on a contract for which the railroad paid \$1000.

No. 2 is on the northwest corner of Kirkham and 5th street. It has a 10-inch bore, is 185 ft. deep and furnishes 6000 gallons per hour. It cost \$600.

No. 3 is a 12-inch bore, corner Pine and Taylor, 130 ft. deep; furnishes 8,000 gallons per hour; cost \$550.

No. 4 is a 7-inch bore, and is on the corner of Wood and Taylor Sts. It gives 2,000 gallons per hour; is 128 ft. deep; cost \$200.

No. 5 is on the corner of 11th and West 5th; is a 7-inch bore, 260 ft. deep; cost \$650, and yields 3,000 gallons an hour.

No. 6 is on the corner of Castro and 10th. It is a 7-inch bore, 330 ft. deep; cost \$700, and gives 3,500 gallons an hour.

No. 7, on the corner of 7th and West, is a 7-inch bore, 400 ft. deep, costing \$800; yields 3,000 gallons an hour.

No. 8 is a 12-inch bore, corner of Adeline and 5th street, 185 ft. deep, yielding 10,000 gallons an hour, and costing \$800.

No. 9 is on 2d, near Clay. It is 12 inches in diameter, 285 ft. deep, yields 10,000 gallons an hour, and cost \$900.

No. 10, on First St., near Jefferson, is a 12-inch bore, 240 ft. deep; capacity, 10,000 gallons per hour; cost \$800.

No. 11 is on the corner of 20th and Market. It is a 7-inch bore, 160 ft. deep; capacity 7,000 gallons, cost \$370.

No. 12 is on Telegraph Avenue and Durant St., is 11-inch bore, 70 ft. deep; yields 3,000 gallons, and cost \$265.

No. 13 is on 10th and Clay Sts.; is a 7-inch well, 90 ft. deep; yields 2,500 gallons an hour, and cost \$120.

These statements of the different wells of varied depths at several parts of the city will show the yield and cost. This list embraces the largest wells in Oakland proper, but only about a twentieth of the number. In many so-called surface wells, generally four or six inches in diameter, good water is obtained in from 40 to 60 ft. Some of these have a capacity of from 1,500 to 2,000 gallons per hour. The water usually rises to within 7 to 14 ft. of the surface. The water is usually cold, but in some deep wells is moderately warm.

In Oakland the usual, in digging wells, find a sand stratum from 40 to 50 ft., then clay stratum from 20 to 100 ft., then the water is usually struck on gravel or coarse sand. Sometimes a cement or concrete of gravel and clay is found—a blue deposit, somewhat moist, like the dark mud of this bay, compressed to the consistency of cheese, and underneath this, a stratum of clam or oyster shell debris; under this shell debris, there is always a seam of water, and then always clay.

The water stratum seems to exist on undulating strata of sand or gravel, at the highest points seeming to exist in sand, at the lowest in gravel. It is seldom that any considerable obstructions are met with in boring, although redwood logs have been encountered in several instances at the depth of about 84 ft.

There appears to be an inexhaustible supply of good water, and our informant, Mr. Spence, and other practical men, have no doubt that a city of more than three times Oakland's present population (of 38,000) can be constantly and abundantly supplied, and that at moderate cost.

We recommend the city council of Oakland to appoint a committee to investigate and report on the best and most feasible plan for the city government to supply the citizens with water for domestic use, and for protection from fires. Had Oakland provided and furnished both water and gas for its citizens for a trifle over cost during the first five years, its population would now be 60,000. It would be more of an inducement to new settlers than many imagine who have not thought of the subject. The subject of good water in our cities is of more than local importance, as people all over the State look to the centers of population as points most suitable for the education of their children. Of course they prefer, other things being equal, to find a place where water, the great necessary of life, is abundant and pure. We shall be pleased from time to time to receive further information from Mr. Spence, and other practical well-borers, concerning the progress of well-boring in Oakland, and in other parts of the State, as we propose to give continued attention to this all-important subject.

JUSTICE.—At the meeting of the Justice Mining Co. held last week, the following directors were elected. Washington Ayre, H. M. Levy, Gustave Frank, J. P. Cavallier, John Scott Wilson. At a subsequent meeting J. P. Cavallier was elected President, R. E. Kelley, Secretary, and Matt. Canavan, Superintendent. The receipts for the year were \$137,276, of which about \$125,000 was from assessments. The pay roll for the year, was \$16,348. The expenses charged to "legal" were \$53,793. When it takes over \$50,000 to pay the lawyers during the same time it takes only \$16,000 to pay the miners, the mine had better be stopped as a mine, and the attention of the stockholders turned to something else. "Justice" ought to be satisfied when that much money is spent in one year for lawyers. No wonder there was an opposition ticket in the field.

MINING COMPANIES' BOOKS.—At a meeting of the stockholders of the Mt. Potosi Mining Co., a new Board of Directors was elected as follows: J. M. Day, M. R. Levenson, H. Lowden, N. D. Thayer and J. N. Fish. The new Board organized by electing M. R. Levenson President, and he demanded of R. A. Holmes the books of the company, which the latter refused to give up. He warned Holmes that he was liable to criminal proceedings for refusing, and again demanded, as a stockholder, to see the books of the company, and the latter refused to give them up. H. Lowden called the Secretary's attention to the law requiring such books to be open for inspection by stockholders on demand, during business hours. Holmes said it was after business hours, and refused to show the books. Thereupon Holmes, on motion, was dismissed as Secretary, and J. H. Sayre was chosen by the new Board of Directors. The old officers claim that they are still in power.

## High Explosives.

[Written expressly for the Mining and Scientific Press,  
by M. EISELER.]  
Number Six.

## Compressed Gun Cotton.

Through the systematic study of Abel, an eminent chemist, this material has now attained quite a position in England, as by means of his analytical and synthetical researches he has found the causes of the instability observed in that substance, and has traced its occasional liability to undergo spontaneous combustion to the presence of minute quantities of foreign substances of comparatively unstable character, produced by the action of nitric acid upon resinous or fatty substances retained by the cotton fibers.

Some parts of his mode of manufacture may be considered comparatively safe, as he carries it on with the material in a wet, therefore unflammable state. His mode of converting it into a minute state of division is the main improvement which he introduced, as it allows of a more perfect cleansing, and then its conversion into highly compressed masses are the main features of his mechanical modifications; otherwise, he admits: One has only to follow Von Leuk's plan, and adhere to his rules.

## Manufacture.

The process of manufacture as pursued by Prentice & Co., or the Liverpool Cotton Co., is as follows:

Clean cotton waste, picked as free as possible from foreign matter, is brought into a uniform and open condition, by being passed through a carding engine.

The rolls thus obtained are dried in a triple cylinder, by means of a steam jacket.

When completely dried it is placed in large tins and carefully covered.

After standing in these till quite cold, the cotton is weighed out in quantities of 1 lb. each, and carried by a boy to the dipping vessel. Here each pan is charged with about 12 gallons of a mixture of 3 volumes of sulphuric acid, 1.84 specific gravity, and one volume of the strongest nitric acid, the whole being kept cool during the action by currents of cold water, which circulate around the vessel.

In this mixture the cotton is dipped, and after it has been in about three minutes the workman lifts it onto a grating, just above the acids. Then, with a movable lever, he gently squeezes it until, roughly speaking, it retains about ten times its weight of the liquid.

Thus saturated with the acids, it is allowed to remain in well-covered earthenware pots for 24 hours, the pots during this time standing in a shallow trough containing water, to keep down the temperature, sufficient acid being added to cover the cotton. The chemical change in the cotton is now complete, and the further processes are for washing and pressing.

First, the large excess of acid is driven off by a centrifugal machine, and the waste acid is caught by a jacket surrounding the revolving portion of the machine, and collected in a receiver. These machines are on the principle of the wringing machines employed by laundries to dry clothes (whizzer).

On leaving the centrifugal machine the gun cotton has to be washed. This operation also requires great care, because the acids which the gun cotton yet retains would give rise to a considerable development of heat, if mixed slowly with water. At such an increased temperature the gun cotton would be decomposed, or "fired," as it is technically called. Therefore it has to be brought at once in contact with a large body of water.

To perfect the washing, the cotton is subjected to the action of water for one, two or three weeks, and afterwards boiled in large vats by the injection of steam. By this latter operation the less stable compounds are destroyed and extracted and the purified gun cotton is transferred to the heating tanks.

This is a simple contrivance for converting the gun cotton into pulp. It is a machine similar to the one used in paper mills and called Hollander.

The pulp is now removed from the tank to a poacher, where it is agitated with a large quantity of water by a wheel, and here it has to be washed till it answers the heat test, which the chemist now applies.

When his report is favorable, the pulp is transferred to a vat and mixed with a small quantity of caustic soda.

The further processes of abstracting the water and moulding the pulp into cartridges or other shapes, is performed by hydraulic pressure or other pressing machines, which are very ingeniously arranged, and great credit is due to the manufacturers for the nice and elaborate machinery they have adopted for the treatment of their products.

Where the cartridges are made under light pressure they are put on perforated trays, and dried in chambers heated with hot air.

In establishments where the gun cotton is mixed with oxidizing salts, these are mixed in regular gun-powder incorporating mills, of light but very elegant pattern.

The great difference between the process of manufacture described above, and that of Von Lenk, consists in the introduction of the pulping operation devised by Abel. This improvement admits of very searching purification, and

also of more reliable testing, and of the subsequent compression.

## Properties.

Before it has been reduced to pulp, gun cotton has the same appearance as the original fiber, but it is harder to the touch; it has neither taste nor smell.

It is insoluble in water, ether or alcohol. Dilute acids and alkalis have no action upon it, but a lower substitution product is formed by the action of nitric acid of the specific gravity, 1.45.

Strong sulphuric acid dissolves it with difficulty.

Caustic potash dissolves it.

Much uncertainty prevailed for a long time as to whether gun cotton was liable to spontaneous combustion or not. As I have shown in my former articles, it had been used in Austria for 12 years, where it underwent the severest tests, and was held by the best authorities to be perfectly safe, but it was at last rejected on account of its instability, and also that other governments abandoned it after experimenting with it extensively. Prof. Abel, in his valuable researches, ascribes the reason of its decomposition to be mainly due to impurity, generally resulting in the process of manufacture, from the action of the acids on resinous matter in the imperfectly washed cotton, and certainly the experience of the last few years speaks in favor of his theory, as no accidents from that score are on hand.

It is only in late years that the true cause of chemical instability, which belongs to the whole class of nitrated organic compounds, has been clearly defined, it being the life question of our modern high explosives.

After their nitration a certain portion of acid—sulphuric, nitric and hypo-nitric—always adheres to those compounds, more or less, according to their form and structure. From a liquid explosive substance like nitro-glycerine, the acids are easily washed out by churning it with water first and then with alkaline solution. But

The large amount of carbonic oxide is very deleterious and even dangerous when pure gun cotton is exploded in a close place.

It is very clear to my mind why English manufacturers have adopted the admixture of oxidizing salts (saltpetre, nitrate of baryta) with gun cotton, as the oxygen contained in the salts effects a more complete combustion, rendering the resulting gases less obnoxious than those resulting from pure gun cotton.

## Gun Cotton in Mining Operations.

In the compressed form, gun cotton is susceptible, like nitro-glycerine and its preparations, of explosion through the agency of an initiative detonation (cap). Compressed gun cotton may therefore be applied with the same facility as dynamite and analogous substances in all mining and blasting work. On a whole the mixture of gun cotton and salts are not as sensitive to concussion as dynamite, consequently an extra strong cap is required to detonate it. As the highest nitrated product of cellulose (trinitro) still demands 24.24 parts of oxygen for the conversion into carbonic acid of the carbon in 100 parts, it is evident that the most explosive gun cotton producible must be inferior in explosive power to nitro-glycerine, which contains a very slight excess of oxygen. Some authorities claim that in spite of its high state of compression to which English manufacturers have brought it, that its strength is much less than dynamite.

Here, also, it is clear why the English manufacturers have adopted the use of an admixture of oxidizing salts, as stated before; but the question will present itself: Is not the quickness of the explosion less rapid through this admixture than of pure cotton?

Where great local action is required, nitro-glycerine or dynamite compete advantageously with those substances. Some careful comparative experiments made by the German engineer corps, at Graudentz, with Nobel's dynamite and Abel's compressed gun cotton (made at the English government works), demonstrated that dy-

needs no thawing out, which is appreciated in cold climates. It does not suffer from exudation, and when properly made has good keeping qualities.

One great advantage again of nitro-glycerine and its preparations is, that they remain unaltered under water and can be used in wet, holes with the same facility as in dry holes, and although compressed gun cotton when containing 10% or 15% of water can be exploded, it requires a very strong exploder or a dry primer to accomplish it, consequently for work under water dynamite is preferred.

The cost of these two materials also differs greatly; the expense of producing gun cotton must be 20% or 25% higher than dynamite; therefore, when the question of competition arises, the latter has the advantage.

To the last six or seven years there have been brought forward in England (since Abel perfected his system of reducing gun cotton to a fine state of division and compressing it) several special preparations of gun cotton, for which peculiar merits are claimed by their advocates. One of those preparations, manufactured by the Gun Cotton Co., is a mixture of finely divided gun cotton and saltpetre. Another, the Tonite Co., at Faversham, mixes gun cotton with nitrate of baryta. Which of these is the best, practical experience alone can form the estimate.

## The Walrus.

Eminent naturalists have remarked that the walrus, or sea-horse, appears to be the connecting link between the mammals of the land and those of the water. This bulky and unwieldy animal when on shore has some resemblance to the seal, yet differs materially in its proportions, as well as in its elephant-like tusks. The walrus attains the size of the largest sea-lion, and measures from 10 to 14 ft. in length, and about 8 ft. in circumference. Its head is rounded,

small (when compared with the anterior portion of the body), and flattened in front. Its eyes are diminutive in size, and deeply set; the small orifices of the ears are about 3 inches behind, and 2 inches below the eyes. The cheeks are studded with 400 or 500 spines or whiskers, some of which are rudimentary, while others grow to the length of 3 or 4 inches. They are transparent, curved, abruptly pointed; and about the size of a straw, but not twisted, as has been stated by some writers. Its neck is short, and its unwieldy body is largest about the chest. Its posterior is abrupt.

The tusks of the walrus are not only a means of defence, but are used in obtaining food, and in mounting the ice-floes, when the shore is not accessible. The canine teeth, as they are sometimes called, may average 2 ft. in length, including the root, which is imbedded in the jaw 6 or 8 inches. Yet some individuals have been taken with tusks 2½ to 3 ft. in length, and each weighing from 10 to 20 lbs. In shape they are somewhat bowing, and slightly hollowed, notched and ridged at their bases. At their junction with the skull, they are about 3 inches asunder; they project at an obtuse angle from the

upper jaw, and, in some instances, meet at their extremities; while others grow perpendicular to each other, or turn outward on each side. There is considerable diversity in their length, shape and size, even in the full-grown tusks, some being very short and stout, while others are elongated and slender. The walrus has no sharp incisors like the seal. The nostrils are placed on the superior portion of the snout, through which the animal appears to inspire, and expires through its mouth, as it dips its head below the surface, blowing up the water into spray, in such a manner as to resemble the spout of a whale. The skin of the animal is thick and somewhat spongy, but exceedingly tough. The hair that covers it in most adult individuals is short and of a dark brown; yet there is no lack of examples where it is of a much lighter shade, or a light but dingy gray. Unlike others of the seal tribe, the animal is abundantly infested with vermin. Under the skin lies the coating of fat which yields oil—it is from 2 to 3 inches in thickness. The appearance of the fully developed walrus in the water, with its long tusks, which seem like an incumbrance, has a striking contrast with that of the common seal. The young, however, before its cumbersome canines protrude, resembles the latter in general form, but is of a black color. On land the walrus is comparatively inactive and clumsy in its movements; but in the water its motions are easy and vigorous. Its geographical distribution quite encircles the globe in that colder belt of the northern hemisphere, above the latitude of 45°, and but few individuals are met with south of 47° north. In Behring sea they are found as far south as the shores of the peninsula of Alaska, and in the Pacific ocean about several of the islands which fringe the central coast of Alaska Territory. They feed upon shell-fish and other submerged marine productions. The walrus is gregarious, being sometimes found in herds upon the ice, and at the proper season the animals collect upon the beaches, or they clamor upon rocky islets in remote places. These interesting facts, as well as the engraving, we take from Capt. Scammon's elegant work on the "Marine Mammalia."

The Piutes are leaving the Comstock for Walker river, Humboldt, etc., being afraid to stay among the whites any longer on account of so much small-pox being in Gold Hill,

THE WALRUS—(Rasmarus Obseue)—DRAWN BY H. W. ELLIOTT.

a granular, flocky or fibrous material, like cotton, retains the acid with far greater tenacity, particularly the nitrous and hypo-nitric acids, which every nitrated organic compound has a strong tendency to retain.

It is quite clear that if there is hypo-nitric acid present, that highly corrosive material, which attacks almost every organic compound, even at the ordinary temperature, must be removed; if not, it will slowly, but surely, lead to an incipient decomposition, which, acting on a nitrated substance, sets free portions of dioxide of nitrogen or hypo-nitric acid.

From nitro-glycerine the corrosive acid is washed out with the utmost facility, and from the moment when the importance of that operation became fully appreciated it has never been neglected. Hence the chemical stability exhibited by dynamite under all conditions of climate.

Although nitro-glycerine has exhibited, upon the whole, greater chemical stability than gun cotton, yet it acquires that superiority only after being thoroughly purified from acid at the factory. When it contains free hypo-nitric acid it cannot be stored at all in hot weather, and even during the course of its manufacture it has several times given rise to a decomposition, ending with explosion and loss of life. The instability of the crude article contrasts so strongly with the stability of the pure nitro-glycerine in dynamite as to remove every trace of doubt regarding the decomposing influences of the adhering acids.

## Fumes.

Amongst the most grievous complaints of miners about modern explosives, is the poisonous nature of the fumes emitted, which exposes them to most serious inconveniences.

The gaseous products of the explosion of gun cotton differ from those of nitro-glycerine, as gun cotton lacks 24.24 parts of oxygen in 100 for the complete conversion of its carbon into carbonic acid, consequently we have the following to be the percentage composition of the resulting gases:

Carbonic oxide.....	23.55
Carbonic acid.....	19.11
Marsh gas.....	11.17
Nitric oxide.....	8.83
Nitrogen.....	8.86
Aqueous vapors.....	21.93
	98.15

namite produced somewhat greater local or shattering effects than gun cotton.

The plastic condition of dynamite and similar preparations gives them an advantage over the rigid, compressed gun cotton in blasting operations, as plastic powders may be inserted more readily into rugged and uneven bore-holes, and may be made, by application of pressure, thoroughly to fill the part charged. Every miner is aware of the importance of having his charge well home in the bottom of his hole, filling the whole cavity. And this can only be accomplished with a plastic powder.

The increased effect derived from this mode of applying plastic explosives is far greater than is generally believed.

Volume for volume, it is impossible to put the same weight in a bore-hole for a certain given space; or, in other words, if one has a cartridge of dynamite, say one inch diameter and four inches long, and one of compressed gun cotton of the same size, the dynamite cartridge will weigh more; consequently one has more explosive material in the same space, owing to the higher specific gravity of dynamite, and as a consequence larger bore-holes are required when using gun cotton, which increases the cost of mining.

The cartridges of compressed gun cotton are rigid, stiff, and every miner knows there should be no air-chamber round the charge, for the expansion which it causes not only lessens the power in proportion to its dilution, but actually decreases the tension of the gas in a much greater measure. Stiff cartridges cannot be introduced into a bore-hole without leaving a considerable air chamber round the charge, particularly as bore-holes generally deviate a great deal from the circular shape.

It is difficult to calculate even approximately the relative proportions of the unoccupied space and the charge, but certainly the loss will amount to considerable. When a loose mass of gun cotton is ignited in the air it burns rapidly away without any explosive effect. But if the ignition takes place in a closed chamber, the gaseous first produced immediately penetrate the mass of the cotton, and the whole is instantaneously decomposed. According to some authorities, gun cotton will not explode below a temperature of 280° F.

Gun cotton has the great advantage over dynamite that it does not freeze, and therefore

HOME PRODUCTION.

HOME MANUFACTURE.

## BERKELEY LUBRICATING OIL WORKS, BERKELEY, CALIFORNIA.

Manufacturers of Machinery and Lubricating Oils, White Wool Oils, Leather Oils and Compounds

**RAILROADS, STEAMSHIPS AND MILLS SUPPLIED AT REDUCED RATES.**

Our oils are produced under a new process, and guaranteed to be Superior to any oils in the Market.

MINING PROPERTIES EXAMINED

AND REPORTED ON

FRISCO, BEAVER COUNTY, UTAH.

RICHARD C. REMMEY, Agent,

**Philadelphia Chemical Stoneware Manufactory.**

1100 E Cumberland St., Philadelphia, Pa.

Manufacturer of all kinds of Chemical Stone Ware for Manufacturing Chemists. Also, Chemical Bricks for Glover Towers.

HOWLAND'S PULVERIZER Takes the Place of the Cumbrous Stamp Mill and can be put up in one day ready for work.

IT HAS BEEN FULLY PROVED AND TESTED.

It weighs complete, 7,000 pounds. It costs \$1,600 ready for the belt. Will crush one hour of hard quartz that will pass through a 48-mesh screen. The wear is less in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.

Stamp Mills' Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chlorinating Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supply. Iron Work complete for Wood Frames, also

SPERRY'S  
WROUGHT IRON FRAME  
FOR STAMP MILLS.

Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 500 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.

MOREY & SPERRY—Warehouses, 92 and 94 Liberty St., N. Y.

### LEFFEL'S IMPROVED WATER WHEEL.

PRICES REDUCED!

PATENTS REISSUED 1868.

The "OLD RELIABLE" with improvements, making it

THE MOST PERFECT TURBINE NOW IN USE

Comprising the Largest and the Smallest Wheels, under both the Highest and Lowest head used in this country. Our new Illustrated Book sent free to those owning water power.

Those improving water power should not fail to write us for New Prices, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address

MACHINERY!

Sole Agents for the Pacific Coast for

BUCKEYE  
Engine Company.

J. A. Fay & Co.'s Wood-Working Machinery; Benoit & Sons' Machinists' Tools; Blake Steam Pumps; N. Y. Belt-  
ing and Packing Co.'s Rubber Goods; Sturtevant Blowers and Exhaust Fan; Tanite Co.'s Emery Wheels and Ma-  
chinery; Payne's Vertical Engines and Boilers; Perry's Centrifugal Pump; Judson's Standard Governors; Dreyfus  
Self-Oilers; Gould Mfg. Co.'s Hand and Power Pumps; Eclipse Windmills; Dieston & Sons Circular Saws; Otto  
Silent Gas Engine; Deane's Elevator Cages; Ballard's Oak Tanned Baling.  
Also on hand and for sale A FULL LINE OF MILL AND MINING SUPPLIES.

GOLD MINERS  
WORKING PLACER, GRAVEL AND QUARTZ MINES,  
SAVE YOUR GOLD!  
- BY USING -  
SILVER PLATED AMALGAMATING PLATES.

The most economical and successful process now in use. Will warrant my Plates to save a very much larger  
percentage of gold than any other method.

SWING AND RIFFLE PLATES for Saving Float Gold Made to Order.  
OLD MINING PLATES BOUGHT, TAKEN IN EXCHANGE FOR NEW, OR RE-PLATED.  
ALL KINDS OF METAL GOODS PLATED!  
San Francisco Gold, Silver and Nickel Plating Works,  
653 and 655 Mission St., bet. New Montgomery and Third, San Francisco.  
Send for Circular. EDWARD G. DENNISTON, PROPRIETOR.  
Awarded First Premium at Every Fair of the Mechanics' Institute  
for the Last Twelve Years.

IRRIGATION!

Land Reclamation!

THE TURBINE PUMPS.

3,000 to 15,000 Gallons a Minute. Strong, Durable and Cheap.

SAN FRANCISCO TOOL COMPANY, - - - No. 21 Stevenson Street, S. F.

ALEX. DEL MAR,

Mining Engineer,

Formerly Director of the Bureau of Statistics of the  
United States; Superintendent of the United States  
Special Commissioners of Mines; Member of the  
Committee on Mines at the Congress of Na-  
tions held in St. Petersburg, Russia;  
Mining Commissioner for the United  
States Monetary Commission;  
author of a History of the  
Precious Metals, etc.  
216 Sansome St., San Francisco.  
Mining properties surveyed and reported upon; assays  
and quantitative analyses made of ores etc.

OTTOKAR HOFMANN,

(Of the Firm of Hofmann Bros.)  
Metallurgist and  
Mining Engineer.

Erection of Leaching and Chlorination Works a specialty.  
Working Tests and Reports made.  
415 MISSION STREET, SAN FRANCISCO.

SAVE YOUR  
GOLD AND SILVER.

I am prepared to demonstrate, if miners will bring me  
from 500 pounds to a ton of their ores, that I can save  
from 25 to 100 per cent. more than any other machinery  
now in use. I will make no charge.  
Machinery can be seen in operation every day at  
No. 143 Fremont Street.

M. B. DODGE.

TAYLOR & BRUNTON,

Mining and Mechanical Engineers.

DESIGNERS AND BUILDERS OF  
MILLS AND METALLURGICAL WORKS,  
FOR THE TREATMENT OF  
Gold, Silver and Copper Ores.

Mines examined with a view of determining their value,  
and the method of treatment best adapted to their product.  
Will furnish estimates, plans and specifications, and super-  
intend or contract for the erection of all kinds of Mining  
and Milling Machinery.  
Leadville, Colorado, P. O. Box 2039.  
New York Branch Office, 63 Broadway, P. O. Box 203.  
S. F. Agents, Prescott, Scott & Co., 61 First St., P. O. Box 2128.

The Explorers' and Assayers' Companion,

By J. S. PHILLIPS, M. E.  
(Third edition.) Price of Vol. 1, \$3.  
Forwarded (post-paid) from the MINING AND SCIENTIFIC  
PRESS Office, by DEWEY & CO.

SELBY  
SMELTING and LEAD CO.

416 Montgomery Street, S. F.

Gold and Silver Refinery  
and Assay Office.

HIGHEST PRICES PAID FOR  
Gold, Silver and Lead Ores and Sulphurets.

Manufacturers of Bluestone.

ALSO, LEAD PIPE, SHEET LEAD, SNOT, Etc.

This Company has the best facilities on the Coast  
for working

GOLD, SILVER and LEAD  
IN THEIR VARIOUS FORMS.

Frink's Patent Silver-Plated Corrugated Glass  
Reflectors and Sun Lights for Lighthouse and  
Ventilating Churches, Halls, Stores, Etc.

Patent Mill and Street Lamps to Burn Coal  
Oil, Kerosene and Gas.

BOESCH'S PATENT

Hydraulic Mining and Locomotive Head Lights, with the  
Latest Improvements, making them the best and  
cheapest in the market.

Pacific Lamp and Reflector Factory.

569 Mission Street, San Francisco.

DR. STARKEY & PALEN'S

PHILA. PALEN TREATMENT PENN.

COMPOUND OXYGEN

SOLD BY INHALATION 606  
H. E. MATHEWS, 606 MONT'G ST.  
SAN FRANCISCO.

A NEW TREATMENT  
-FOR-  
Consumption, Asthma, Bronchitis,  
Dyspepsia, Catarrh, Headache,  
Neuralgia, Debility,  
Rheumatism,  
And all CHRONIC and NERVOUS DISEASES.

PACKAGES CONVENIENTLY SENT BY EXPRESS, READY FOR US  
AT HOME.

A Treatise on Compound Oxygen, giving the history  
this new discovery, and a large record of most remarkable  
cures, will be mailed free to all who ask for it. Also,  
"Health and Life," a quarterly journal, containing much  
interesting information. Write for it, Address the proprie-  
tors, DR. STARKEY & PALEN, 103 and 111 Old  
street, Philadelphia, Pa., or H. E. MATHEWS, 606 Mont-  
gomery street, San Francisco, Cal., from whom can be  
procured both information and supplies.

WHEELLOCK

AUTOMATIC  
CUT-OFF  
ENGINE

INDORSED BY THE MOST EMINENT  
ENGINEERS OF THE COUNTRY AS  
THE MOST ECONOMICAL AND PER-  
FECT WORKING ENGINE NOW MADE  
AND THE BEST PIECE OF STEAM  
MACHINERY THE MECHANICAL IN-  
GENUITY OF THE TIMES HAS YET  
PRODUCED. CAN BE SEEN IN  
OPERATION AT THE PACIFIC IRON  
WORKS, RANKIN, BRAYTON & CO.,  
SAN FRANCISCO. SEND FOR CIRCULAR.

## PATENTS AND INVENTIONS.

### List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," U. S. and Foreign Patent Agents.]

FOR THE WEEK ENDING APRIL 26, 1881.

240,572.—PADLOCK.—P. H. Baker, S. F.  
240,555.—CLEANING SEWERS.—P. Burke, Virginia City, Nev.  
240,597.—PRODUCING ARTIFICIAL COLD.—J. F. Gesner, San Rafael, Cal.  
240,723.—SPREADER.—W. F. Jeans, Woodland, Cal.  
240,752.—GUIDE FOR PENMAN.—E. Numan, S. F.  
240,756.—VALVE MOTION.—E. O'Neill, S. F.  
240,558.—PLOW.—E. Squires, Beaverton, Or.  
240,567.—GATE.—J. and A. Wright, Rohnerville, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

### Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

**BEDS.**—Frederick Roehner, Oakland, Alameda county, Cal. Dated May 3, 1881. No. 241,071. This invention is an improvement in beds consisting in the combination of a peculiarly constructed mattress and a roller journaled at the head of the bedstead upon which the mattress is fitted, and by means of which it can be easily moved. The idea is to provide a means by which a heavy top mattress can be readily changed to render every part serviceable. The ordinary mattresses are heavy and unweildy. Considerable exertion is required to turn them over when necessary. It is also evident that the number of different changes is limited, or that when the mattress is used in one position and becomes pressed down and hardened in the place where the weight of the body rests, it can only be changed by turning the mattress over. Thus only a portion of the mattress is brought into use, by being subject to such few changes. The hair or other filling of the mattress becomes hardened in certain places, and long before it is worn out becomes uncomfortable and practically useless. Its great weight makes it a task to turn it. One would therefore be less inclined to perform this operation often. To provide a mattress equally good, but with less weight and one capable of being changed and turned to more advantage by bringing more of itself into use, has been the endeavor of upholsterers. One method is to make the mattress in two or three pieces. For double beds the mattress is cut so as to leave the larger section square. The smaller section is put at the head. The weight of the body will press upon the larger piece toward its outer boundary. It is manifest that being square, it can be moved in four changes on one side and four on the other, and being lighter than a mattress, is easily changed; but while this answers for double beds, it cannot be used upon three-quarter or single beds, because these latter sizes, while retaining their length, narrow their width, and it is consequently impossible to form a square section out of the mattress without bringing the line of separation down in a place too low for comfort and use. The only method which can be used for beds smaller than the double bed, is to form the mattress in three pieces. This is, however, objectionable as being troublesome. This account of the state of the art will show why Mr. Roehner made his invention. He makes the top mattress in the shape of a band or ring, the thickness of both sides being equal to that of an ordinary mattress. A roller passes through the mattress at its head. To move it the person stands at the foot of the bed and catches hold of the mattress by its lower part, and pulls it so as to turn it on the roller. In this way every portion of the mattress can be used.

**CABLE-TRAMWAY FOR CARRYING CARS AROUND CURVES.**—Sehra R. Mathewson, San Francisco, Dated May 3, 1881. No. 241,044. This is a system for cable roads to enable the cars to pass around curves. It consists in arranging a series of upright rollers, and intermediate plates within the tunnel or tube within which the cable runs, the said rollers and intermediate plates forming a practically continuous surface, over which the cable and grip pass whereby the grip may pass around curves and corners of streets and the grip be carried smoothly around said curves. It further consists in the peculiar construction of the vertical and horizontal or guide rollers whereby friction is reduced. The difficulty heretofore has been, in constructing cable roads which will permit cars to pass around curves, in the fact that the grip cannot, by reason of the strain of the cable, pass over the space between the rollers. The difficulty of providing rollers having such little friction as to permit a cable to pass around a curve, has prevented any attempt to make a grip pass around also, because of the manifest increase of friction. The grip not being pliable like the cable, cannot conform itself to the curve, and will not follow the cable sufficiently to prevent it from either striking against each roller on a curve and jarring the

car, or passing it with such friction as to render the attempt practically futile. In this invention rollers are provided which will reduce the friction to a minimum, and by reason of the intermediate plate the grip can be conducted from one roller to the other without jar and with little friction, thus rendering the passage of the grip around the curve possible.

**ANIMAL SHEARS.**—John J. Bogard, Dated May 3, 1881. No. 240,953. This invention relates to certain improvements in that class of sheep shears which are constructed of several parts, the object of which is to render the blades detachable. It consists in providing each of the blades with an extended shank, by which they are attached by a peculiar joint to the arms or handles of the spring bow. The object of the inventor is to make a joint securing the blades to the handles, which, while permitting them to be easily detached therefrom, where necessary, will be firm in itself, are so constructed that natural wear will, on the contrary, make it as tight and firm when in use as at first.

### Expenditures on Claims.

**EDITORS PRESS.**—Permit me to say that I consider the recent ruling of the Commissioner of the Land Office in the case of the Boh Ingersoll mine, referred to in your last issue, to be in conflict with common sense and constitutional law. It has heretofore been the custom of the Commissioner to construe the laws relating to matters in his department in accordance with justice and reason; but now he decides that a claim is forfeited because a certain work was not performed in the calendar year 1879, when no law was in existence requiring its performance.

At the time of the passage of the amendment of January, 1880, the Boh Ingersoll claim was a valid claim, since the requirements of the act of 1872 had been complied with, and it is absurd to suppose that Congress intended, even if it had the power, which it has not, to make a retroactive law by which that validity should be impaired.

It is true that, under the former law, the Boh Ingersoll would have been forfeited by failure to perform on it a second \$100 worth of work prior to September, 1880, but that law was superseded by the amendment of 1880, and, under a just and constitutional construction of that amendment, all claims which were in good legal standing at the date of its passage, became liable to its operation from the date of that passage, without prejudice to their prior validity. Practically they were, for the purpose of that amendment, in the same position as claims located subsequently to January, 1879, on which no work need be done until any time in 1880.

The absurdity of the position taken by the Land Office consists in the fact that it is manifestly impossible to do work in 1879, or any preceding year, after January 22, 1880, and in holding a person accountable for not having done, in the past, that which he was not required to do by any then existing law.

Aside from the fact that the construction put upon the amendment of 1880 is in apparent conflict with the Constitution of the United States, it is doubtful if it could be sustained by the literal meaning of the language employed. "Shall apply" seems to refer to the future and not to the past; that is, to the conditions of tenure after the passage of the amendment, since an amendment to a law is not usually held to effect the operation of the law previous to the adoption of the amendment.

Had a retrospective operation been intended, it would have been easy and proper to say so, as "this section shall apply retrospectively, etc." If the "present rulings" are to remain in force, or to constitute a precedent for the future, it will not be safe for a miner to absent himself for a moment from his unpatented claim, lest intelligence of some new "retroactive" law be flashed across the continent for the benefit of professional "jumpers." If one could only have foreseen that decision, how easy it would have been to make a fortune—that is, supposing one's brains were not blown out in the attempt.

It does not, however, appear to be necessary for claimants of mines to re-locate their properties, although it might in some cases be convenient to do so. In case of a defective record—in the light (?) of the new decision—it is only necessary to begin immediately to do the \$100 worth of work required for the current calendar year before a re-location can be made by "jumpers," and, under the provisions of the act of 1872, a claim, although forfeited, will thus be restored to validity. It is a pity that the Boh Ingersoll case did not reach the courts, as the decision of the Land Office would almost certainly have been reversed.

The only essential points in which the operation of the new law differs from that of the old are, that under it a locator may, in some cases, have nearly two years, after making a location, in which to perform his first installment of work, and that it settles the disputed question as to applying the excess of work over \$100, done in any one year, to the credit of succeeding years. Doubtless the latter was the object of the framers of the amendment. Under either law it is possible to allow nearly two years to elapse between any two, though not between every two installments of assessment work.

C. H. A.

The Silver Reef striking miners are still in jail.

### The Madera-Mariposa Route to the Yosemite.

Each year something has been done to facilitate access to the Yosemite, and the improvements in this direction are not yet ended. The latest, however, and one which merits especial mention at this time is the improved Madera-Mariposa route, which supersedes the old Mariposa route.

Madera is a town in Fresno county and a station upon the Southern Pacific railway, 135 miles from San Francisco. We shall give some notes of its growth and industries in another column. It has come into especial fame now as one of the points where tourists coming into the State, either by the northern or southern routes, may disembark to reach the Yosemite valley. A new line of splendidly built, strong and safe stages has been put on by the Yosemite Stage and Turnpike Co. The manager of the line is A. H. Washburn, who has been a leader in facilitating Yosemite travel from the early days of trail routes. In company with others he built the old route via Merced and the present Madera-Mariposa route at a cost of over \$60,000. His long experience is of no small value to the public in the way of securing the safety and comfort of his patrons. Mr. Washburn has fitted up the route this year with special cars, and is justly proud of the score of fine, fleet horses which are in the stables of the company. The coaches are stylish and strong, and are well adapted for their work. Every Tuesday morning, and every other alternate morning, two stageleaves Madera, each accommodating 11 passengers. Every Wednesday and every other alternate morning, one stage holding 14, is sent out. Besides these regular runs there are always ready stages and teams by which parties of 80 or more can be carried forward at any time, upon reasonable notice.

Starting from Madera in the morning, the itinerary is as follows: Madera to Stitts, 12 miles; to Green's, 12 miles; to Foster (dinner station), 13 miles; to Fresno Flats (a pleasant mountain village), 7 miles; to Mariposa Big Tree station, 24 miles; to 11-mile station; to Yosemite, 13 miles—in all 90 miles. The stage reaches Big Tree station in the evening. In the morning tourists are carried to the Mariposa groves and returned to the station about dinner time, and thence they are taken to Yosemite, arriving about 6:30 P. M. Returning from the valley, they start at 1 P. M. daily.

Besides the regular trains of the S. P. R. R. passing through Madera, a special express for the accommodation of Yosemite travel leaves San Francisco at 4 P. M., reaching Madera at 11 P. M. Returning the train leaves Madera at 5 A. M., and arrives in San Francisco at 11:45. As Madera can be reached from the south by all trains, there need be no loss of time by those coming to the valley from that direction. The cost of the round trip (to the valley and return) from San Francisco is \$59; from Madera, \$45.

Of the quality of the new Madera-Mariposa route, it may be said that the new road has a remarkably easy grade; so much so that it is said that a four-horse team can trot into the valley. It is considered the best mountain road of its length in the State. The improvement over the Merced route is quite noticeable in the reduced amount of expenditure for breakage and necessary repairs to wagons, as well as in other ways. The owners of the road are disposed to encourage its use, and we understand tolls are to be reasonable as could be expected, considering the cost of constructing the road. Any further information of the Madera-Mariposa route may be had at Miller's Agency, No. 2 New Montgomery street, S. F., under the Palace hotel.

It is an item of great interest in this connection to state that the California Central R. R. is already projected from Madera, and surveys are being made for the early construction of 50 miles of broad-gauge road Yosemite-ward. The project is said to be in the hands of capitalists of determination and abundant means. The road is eventually to pass over the Sierra Nevada, through what is called the Mammoth pass on the headwaters of the San Joaquin river; thence into the Owen River district in Mono county. Such a road would open up a wealth of scenery superior, perhaps, to any yet invaded by the rails on the Pacific coast.

A LARGE Bruckner furnace has been bought for the Windsor Co.'s mill at Pinal, Arizona. The furnace and new machinery will be in running order in about two weeks on the immense mass of rich ore on the dump of the Last Chance and other mines.

GEORGE DALY, the well-known mining superintendent, has struck it rich in New Mexico, as will be seen by the items in our "Mining Summary." This is to assume charge of the new mines being opened by George D. Roberts and others in southern New Mexico.

IDAHO has an area of 55,228,160 acres, of which 12,000,000 acres are agricultural or may be reclaimed by irrigation; 25,000,000 acres of pasture lands; 10,000,000 of timber lands, and the remainder mineral, lava and mountainous lands.

IDAHO bullion, amounting to \$25,000 was received by Wells, Fargo & Co. at Winnemucca the other day.

FIVE arastras are being used at the Invincible mine, Calaveras county.

### News in Brief.

SALMON have reached the McCloud river.

A SMOKE-NUISANCE ordinance has been passed for Chicago.

THE school levy of California has been reduced to \$1,300,000.

THE Senate ratified both Chinese treaties, without amendment.

THE Bey of Tunis steadily persists in refusing the French proposals.

THE Russian government has decided to discontinue public executions.

THE steamer *Belize*, from New Orleans for Copenhagen, has foundered at sea.

THE losses sustained by the cloudburst in Canyon City, Oregon, approximate \$6,000.

FORTY artesian wells have been dug in New York city, upon an average depth of 400 ft.

INDIAN JOHN, chief of the Siuslaws, highly respected by the whites, died on the 18th of April.

KIEFF Jews now in Podolia have been maltreated, and troops have been sent to their protection.

CORK and Kilkenny are proclaimed under the Arms Act; also, King's and Queen's counties.

MARK McDONALD, D. O. Mills, Jay Gould and Dr. Green of the Western Union are coming to California soon.

A CALIFORNIA lion, which measured ten feet from tip to tip, was recently shot on the Noyo river, Mendocino county.

It is stated that the Governor-General of Canada will return to England after his Manitoba trip and resign his position.

IMMIGRANTS are pouring into the country through New York, at the rate of 18,000 a week. The money they bring averages \$100 each.

THE Northern Pacific has contracted for 64,000 tons of rails to be delivered this year. This will equal 550 miles of road. All but 5,000 tons are steel.

CARDINAL MANNING has forbidden the use of halls of Catholic clubs, or assembly rooms of total abstinence societies, for meetings of the Land League.

THE State's attorney at Louisville has brought suits for \$350 against the Louisville and Nashville railroad, for running trains and employing men on Sunday.

THERE has been some talk of dividing Texas into two States, but the Texans take little interest in the matter, and say there is no sentiment at home favoring the division.

THE Indians on the Klamath reservation are said to be more industrious than any other tribe on the coast, and are making more rapid progress in civilization than any other tribe.

It is said Princess Louise absolutely refuses to return to Canada, and that the Marquis of Lorne will in consequence resign the Governorship of the Dominion and return to England.

It is said that the arrest of the Grand Duke Constantine will likely be followed by a Nihilist movement of the sailors on the Russian fleet, who are said to have an understanding with a number of other Nihilists at Odessa.

BRITISH residents in the Transvaal are leaving no stone unturned to upset the settlement. There are exaggerated accounts of the doings of both Boers and natives, but there is sufficient truth in them to give cause of anxiety.

AMERICAN machinery, which under the old tariff in France paid from 18 to 36 francs duty, will now pay but six francs, the same as English machinery. A large quantity is awaiting at Havre, to be entered under the new tariff.

THE piles are all down for the National City railroad wharf. They will hereafter build the iron extension. Railroad material keeps arriving in San Diego in greater bulk every steamer. A goodly part of it is taken by lighters to National City.

A Lancashire family, named Siddon, have had a wind-fall of property valued at £4,000,000, which had been in chancery since 1857. The property was bequeathed to John Siddon, who died in the workhouse. His heirs inherit this vast fortune.

THE Bey of Tunis has addressed a fresh protest to the Powers, imploring them in the name of humanity to stay the horrors of war. The report is confirmed that five powerful native tribes have revolted, and refuse to submit either to the Bey or the French.

A DISPATCH from Paris says: It is probable that the Monetary Conference, after an exhaustive discussion, will adjourn for an indefinite period, to give time for direct negotiations between the various States on the basis of the conclusions reached by the Conference.

In the Commons Gladstone moved an address praying the Crown to provide a monument in Westminster Abbey to Beaconsfield. He appealed to the House to not make it a subject of partisan discussion. It was adopted—yeas, 336; nays, 54. A similar resolution was adopted by the Lords.

A DISPATCH from Berlin says that the Free-traders are much dissatisfied at the hills recently introduced in the Federal Council for increasing the duties on grist and introducing a duty on grapes. When the hills come before the Reichstag, the Left intend to introduce a motion for the abolition of the duties on corn.

## Traveling Agents.

We want several canvassing agents who will make it their business to solicit subscriptions and advertising for our first-class progressive newspapers. Men of ability and experience can secure good pay and permanent employment. Send references and state your past occupation, etc., to the publishers of this paper.

### Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. F. OSBORN—San Francisco.  
A. C. KNOX—Sonoma, Napa, Lake and Mendocino counties.  
G. W. McGRW—Santa Clara county.  
M. P. OWEN—Santa Cruz County.  
W. A. WRIGHT—Merced, Tulare and Kern counties.  
N. E. DOWD—San Bernardino Co.  
J. R. C. HOAG—California.  
B. W. CROWELL—Tehama and Butte counties.  
D. W. KELLER—Santa Barbara, Ventura and San Luis Obispo counties.  
A. LEONARD MEYER—Utah, Idaho and Montana Ter.

PERSONS receiving a sample copy of the MINING AND SCIENTIFIC PRESS with this notice marked, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We will send it, on trial, at the rate of \$4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sealions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

A gentleman just arrived from Colorado who is thoroughly posted in the treatment of refractory ores, and who has been a director for 3 years in the Austrian Government Reduction Works in Europe, would like to engage his services to a Mining and Reduction Company, either as Superintendent or Assistant, or to take charge of the Assay Department. Address H. S., this office.

How to STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

The State Mining Bureau, No. 313 Pine street, is open to the public from 10 o'clock A. M., to 5 o'clock P. M. daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

Also Water-Proof Leather Belting.  
NO 13 FREMONT ST., near Market, SAN FRANCISCO

## NEW MINING FIELDS.

Prof. Hayden's Geological survey of the northern wilds, comprising his explorations in the Big Horn, Gray Bull, Yellowstone and Sun River Countries, Wind River, Teton, Little Rocky and Bear Paw Mountains. Their geology and physical features. Where the survey found "paying prospects," going from 6 to 25 cents in gold to the pan. Immense gravel bars prospecting 3 and 10 cents per pan. Water abundant for hydraulic mining. Extensive gold and silver bearing quartz lodes, one mammoth ledge averaging \$15.00 in free gold per ton, from surface croppings. The classes of country rock peculiar to each section, which interest the miner, as being the most congenial for the existence of rich veins and placers. A valuable work (with map), forming a complete intelligible, systematic guide and companion for miners and gold hunters, desirous of prospecting in the northern Rockies and localities mentioned. Terms, \$5 per copy; 5 copies for \$20. Address J. A. CAMPBELL & CO, Evanson, W. Y. Ter. Box No. 119. (Mention this paper.)

## Life Scholarships, \$70.

SEND FOR CIRCULAR.

## Mining & Scientific Press

Is the leading mining journal in America, and enjoys a large circulation among the more intelligent operators and workers in the gold fields of the world.

As a scientific and mechanical representative of the Pacific Coast, it is decidedly popular and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivaled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer will find profit by its reading.

Subscription, \$4 a year in advance. Sample copies, post paid, 10 cents.

LEWIS & CO., Publishers.

## BOOKS.

Relating to Casting and Founding, Electricity, Electric Light, Engineering, Drawing, Manufacture of Gas, Heat, Indicator Diagram, Link Motion, Mechanics, Screw Cutting, Steam Boilers, Steam Engines, Steel Turning, Wire Gauge, Workshop Receipts. Descriptive Catalogue sent on application.

E. & F. N. Spon, 446 Broome St., N. Y.

This paper is printed with Ink furnished by Chas. Emen Johnson & Co., 509 South 10th St., Philadelphia & 59 Gold St., N. Y. Agents for Pacific Coast—Joseph H. Dorety, 527 Commercial St., S. F.

### J. S. PHILLIPS, M. E., ETC.

May still be consulted by old friends. Address No. 1 Wall Street, New York.

Mining Machinery supplied.

San Francisco Cordage Factory.

Established 1856.

Constantly on hand a full assortment of Manila Rops, Sisal Rops, Tanned Manila Rope, Hay Rope, Whale Line, etc., etc.

Extra sizes and lengths made to order on short notice.  
TUBBS & CO.,  
611 and 613 Front Street, San Francisco

## EXCELSIOR BLASTING POWDER

MANUFACTURED BY THE

Excelsior Powder Company.

This is no so-called "safety" Powder, but a powerful explosive, and as safe to handle and use as any nitro-glycerine Powder on the continent. There is no headache or nausea in the use of this Powder, as the noxious fumes are entirely done away with. It is put up in cartridges of any size to suit consumers and is exploded with cap and fuse, the same as any other high explosive. The following testimonial is a sample of hundreds of the same tenor being constantly received:

GOLD HILL, August 17, 1880.

AGENT EXCELSIOR POWDER CO.—Dear Sir:—I have used your Powder in last cement and hard blasting rock, and find it superior to any Powder in use on the Comstock. It does its work effectually, and does not leave the person using it with a severe headache, like the other Powders out to the majority of miners. In recommending it I would suggest, give it a fair trial and I am confident it will speak for itself. Wishing your Company success,  
I am respectfully yours, etc.,

GEORGE OLARK,

Foreman Sierra G. and S. M. Co.

Address all orders to

## Pacific Iron Works.

Established in 1850.

RANKIN, BRAYTON & CO.

Office—127 First Street, San Francisco, Cal.

Builders of Engines, Boilers, all Classes of Machinery.

PLANTS FOR GOLD AND SILVER MILLS,  
Embracing the latest and most Improved Machinery and Processes for Base and Free Ores.

WATER JACKET SMELTING FURNACES,  
For both Galena and Copper Ores of the Most Improved Construction.

Having Built nearly every successful working Furnace on the Coast, we are prepared to guarantee the best results  
attainable in all classes of Ores.

HOISTING AND PUMPING MACHINERY,  
Embracing all Known Improvements.

WHELOCK'S AUTOMATIC CUT-OFF ENGINE,  
Beyond Question the most economical and perfect working Engine now made.

WALKER'S COMPOUND STEAM PUMPS,  
The best in use. Will work with thirty per cent. less steam than any other Pump in the market.

Sole Agent for HOWELL'S IMPROVED WHITE FURNACE.

The only successful Chloridizing Furnace made. Over fifty of them in use on this Coast.

Parties Wanting any kind of Mining Machinery are requested to send for Illustrated Circular.

## DEWEY & CO.'S

Scientific Press

Patent Agency.

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old  
experienced, first-class Agency. We have able and trustworthy associates and Agents in Wash-  
ington and the capital cities of the principal nations of the world. In connection with our edi-  
torial, scientific and Patent Law Library, and record of original cases in our office, we have  
other advantages far beyond those which can be offered home inventors by other Agencies. The  
information accumulated through long and careful practice before the Office, and the frequent  
examination of Patents already granted, for the purpose of determining the patentability of  
inventions brought before us, enables us often to give advice which will save inventors the  
expense of applying for Patents upon inventions which are not new. Circulars of advice sent  
free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

A. T. DEWEY.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with  
Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when ad-  
visable.

STEAM LAUNCHES, Barges and Steam Tugs con-  
structed with reference to the Trade in which they are  
to be employed. Speed, tonnage and draft of water  
guaranteed.

STEAM BOILERS. Particular attention given to  
the quality of the material and workmanship, and none  
but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING  
MACHINERY made after the most approved plans.  
Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size  
made in suitable lengths for connecting together,  
sheets rolled, punched, and packed for shipment ready  
to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and  
Water Pipe made by this establishment, riveted by  
Hydraulic Riveting Machinery, that quality of work  
being far superior to hand work.

SHIP WORK. Ship and Steam Capstans, Steam  
Winches, Air and Circulating Pumps, made after the  
most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City  
Water Works purposes, built with the celebrated Davy  
Valve Motion, superior to any other Pump.

## HUNTINGTON'S Oscillating Stamp Mill

It has no Stems, Cams, or Tappets, and  
Adjusts Itself to the Wear of the  
Shoe and Dies

For Simplicity, Economy, Durability and Effective Work-  
ing, it exceeds anything ever presented to the public, and  
will do the work of five stamps with one-fourth the power.

Price, 900-Pound Hammer, . . . \$500.

## HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

**No. 1 XX is the Strongest Explosive Known.**

**No. 2 is superior to any powder of that grade.**

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

## \$1,000 CHALLENGE!

## THE FRUE ORE CONCENTRATOR.

Over 250 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

Saves from 50 to 100 per cent. more than any other Concentrator in use, and the concentrations are clean from the first working.

The wear and tear are merely nominal; the water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of \$1,000 each, and we mean business.

ADAMS & CARTER, Agents, Room 7, No. 109 California Street, S. F.

**WIND MILL.** One of the best made in this State for sale cheap on easy terms. Address, W. T., care of Dewey & Co., S. F.

## BOILER COVERINGS.

Plastic Cement and Hair Felt, with or without the Patent "AIR SPACE" Method. Cement ready for use by the barrel. G. C. FOWLER, No. 413 Pacific St., S. F.

## HYDRAULIC GRAVEL ELEVATORS,

For working flat gravel mines that have no dump.

Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

**JOSHUA HENDY,**

No. 51 Fremont Street. Office of the Hydraulic Gravel Elevating Mining Co., S. F.

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS.

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive

## Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. <sup>23</sup> Triple Force Caps and all Grades of Fuse.

**BANDMANN, NIELSEN & CO.,**  
 SAN FRANCISCO, CAL.

## "FRUE" ORE CONCENTRATORS.

## A Water Carrying Tortoise.

At a meeting of the Academy of Sciences the other evening, a very fine specimen of the desert land tortoise, from Cajon Pass, San Bernardino county, in this State, was received. The specimen had been carefully prepared, and was as large as an ordinary bucket. This tortoise is a native of the arid regions of California and Arizona, and Prof. E. T. Cox, who was present, related a curious circumstance connected with it.

He found on dissecting one of them that it carried on each side a membrane, attached to the inner portion of the shell, in which was about a pint of salt water, the whole amount being about a quart. He was of opinion that this water was derived from the secretions of the giant barrel cactus, on which the tortoise feeds. This cactus contains a great deal of water.

The tortoise is found in sections of country where there is no water, and where there is no vegetation but the cactus. A traveler suffering from thirst could, in an emergency, supply himself with water by killing a tortoise. They are highly prized by Mexicans, who make from them a delicious soup. The foxes of the desert attack the tortoise and finally overcome it by dragging them at times for miles.

B. B. Redding said he would try to obtain a live one for the Academy, in order that its habits and peculiarities may be carefully observed and noted. He instanced being on the Gallapagos islands in 1849, and assisting in the capture of 92 land tortoises, varying from 450 to 600 lbs. in weight, which the vessel brought to San Francisco and sold for more money than the whole cargo of lumber nested at that time. They were two months on board the vessel, yet ate nothing and those killed had in them considerable quantities of pure water. They live on the high lava rocks, which rise as mountains on the island, where there are no springs or streams, and the only dependence of animal life for water is necessarily upon the irregular and uncertain rain showers.

It may be mentioned that the tortoise are of different species, though they may have the same habit in respect of carrying water. The famous ediths species of the coasts of the Pacific and Indies, of which the headquarters is at Gallapagos islands, is the *Testudo Indica*. They grow to five, six, and even seven hundred pounds or more. Those found in this State are smaller and are the *Agassii* species, first described some years ago by Dr. J. G. Cooper, if we recollect aright. Those Mr. Redding describes from the Gallapagos were offered water while on the ship but refused it. Yet when killed they all contained water. The place they inhabit is a dry one, lacking water. It may be that they go to the high places and obtain it from the vegetation, the same as our species does.

## Stamps in Black Hills.

The Deadwood Times says: If the mines in the hills did not pay, the milling business would certainly not be increased from year to year; that they are a sufficient guarantee for the permanency of these mines. The following is a complete list with the number of stamps:

MINES	STAMPS	MINES	STAMPS
Snodgrass	20	Pearson's	20
Portland	20	Fairview	20
Marshall's	15	Hidden Treasure	30
Gwin Mills	20	Moore's	20
Thompson's	20	McLaughlin's	20
Racine	20	Casey's	20
Morrison & Co.	20	Hildebrand's	25
Homestake	20	Deadwood	110
White's	20	Golden Terra	80
Golden Star	120	Caledonia	60
Highland	120	Elliott's	30
Homestake, No. 2	80	Snyder's	20
Lewis	10	Girdler & Orr	25
De Smet	80	Esmeralda	60
Pinney	20	Ludwick's	20
Great Eastern	20	Spring & Lancaster	30
Union	25	Champion	30
Bogle's	20	Lexington	30
Thompson's	20	Pennington	20
Picket & Hale	30		
Total	1,405		

The Oro Grande mill, San Bernardino county, is working \$40 rock.

## Wood-Working Machinery.

We illustrate herewith a well-designed foot-mortise, constructed by Messrs. Walker Bros., of Philadelphia. This firm is among the late ones to enter the field as constructors of wood-making machines; but these designs show great skill, and some of their machines, we have seen, maintain Philadelphia's reputation.

The San Francisco Tool Co. propose to act as agents for Messrs. Walker Bros., and have now a number of their machines on hand and in transit.

New Mortising Machine.

We expect to illustrate in our future numbers, some of the larger and more important machines made by this firm. The machines are, at this time, scarcely known on the Pacific coast.

A BIG CONTRACT.—The Carson Times says: "Smart & Sons, of Carson, have just completed an extensive logging contract with the Carson and Tahoe Lumber & Fluming Co. The Messrs. Smart have cut, hauled and delivered in a ditch two miles from Rowland's, Lake Tahoe, 4,000,000 ft. of logs, for which they received \$3,500 per 1,000, the contract aggregating \$14,000. The fluming company dug the ditch at a cost of nearly \$3,000. It is fed by the waters of the Little Truckee river, and leads direct to the lake at a point one mile west of Rowland's. The logs are towed across to Glenbrook, then sawed up and thence flumed to Carson."

It is supposed that the celebrated "Blue Bucket" diggings, of Oregon, have been re-discovered. The gold was found in 1845 by the Joe Meek emigrant party, and search has ever since been made for the spot. It is supposed that it is on the Mathew reservation. The prospectors said to have found the place are very secret about it.

## Suction Pipe for Ore-Leaching Tubs.

In Aaron's recently published book on "Leaching Gold and Silver Ores," he describes a method by which, in cases of difficult leaching, filtration may be facilitated by means of a suction pipe. This is simply the discharge pipe of the leaching vat, made of stiff hose, or of wood, instead of soft rubber as in other cases, and extended to a vertical depth of from 6 to 25 ft. The hose, near its lower end, is coiled once around, as in the accompanying diagram, and secured by a piece of wire; or, a re-curved piece of lead pipe may be inserted in the end of the discharge pipe, or again, the end may be immersed in a cup of water, although this plan is less convenient than the others. The object, in either case, is to prevent the entrance of air.

Though not the general practice, it is well to have a vent pipe to prevent disturbance of the filter by the air or gas beneath it, when displaced by the entrance of water, especially if the discharge pipe is hung up, closed as in the case of using suction, or occupied by the introduction of water below the filter, as in com-

Suction Pipe for Leaching Vats.

mencing the washing of silver ore. There are several methods of arranging a vent pipe. Perhaps the simplest is the following, represented by a dotted line in the diagram.

When the ore vat is disconnected from the chlorine pipe a short piece of rubber tube is connected at one end with the nipple through which the chlorine was introduced, and at the other with the upper part of the vat, by being inserted tightly in a hole bored through the side, just below the cover. The short tube may be left permanently on the lead nipple, and connected with the chlorine pipe.

Whether water is introduced from above or below the ore, the air or gas beneath the filter will pass through the tube, and return to the vat above the ore. If the chlorine nipple is to be used thus as a vent, it should be set in as high as possible, consistently with the delivery of the chlorine below the filter. A special vent pipe may be made by boring a one-quarter inch hole lengthwise through a strip of wood, and attaching the strip to the inside of the vat by means of wooden pins. It should terminate at one end immediately below the vat cover, and at the other, beneath the hurlap on the gravel. The upper end must be plugged, and a transverse hole bored to connect with the vertical passage. This aperture must be plugged during the chlorination, and opened when water is admitted.

## Academy of Sciences.

At the regular meeting of the Academy of Sciences held on Monday last, Governor Geo. C. Perkins and Hon. James G. Fair were both nominated for life membership. A very perfect specimen of stone axes, found on the Tucon mountains, Arizona, was presented by E. P. Gerald. Prof. Davidson, Mr. Redding, Prof. Cox, all thought it the most perfect specimen they had seen. W. W. Dodge presented two specimens of a very rare bird—emperor geese, from 2,200 miles above the mouth of the Yukon river, Alaska.

Two horned toads and a fine collection of carboniferous fossils from the confluence of the White Mountain and Black river, Nevada, from Patrick Gannon. An ovary of a common hen, containing over 500 undeveloped eggs of all sizes, from Mr. Pyson. A desert-land tortoise from Cajon Pass, San Bernardino county, originally described by J. G. Cooper, and named after Prof. Agassiz. It was presented by Tay & Lawrence. We refer to this donation in another column.

Prof. Davidson said he had carefully examined the famous Danish collection of stone axes at Copenhagen, and also that at Washington, and in neither had he observed any equal in beauty of form, and so perfect as the stone axes presented last evening.

Mr. Redding said this kind of stone axes was only found in Arizona and New Mexico, among a pre-historic people who built houses and used rafters to make partitions, which they cut and dressed with these stone axes. They are well adapted to splitting wood.

Dr. H. W. Harkness said these beams in the Casa Grande appeared to have been thus hewn. Prof. Cox said axes somewhat similar in form were found in Ohio, Indiana and Kentucky.

Dr. Harkness reported his microscopic observations on a package of what purported to be part of a shower of sulphur, but turned out to be the fine pollen of a species of pine tree. These grains float easily in the air, and blow to great distances. Whirlwinds sweeping through pine forests carry them often a thousand miles, and when they fall on snow-covered surfaces, the effect is often startling. These popularly misnamed sulphur showers are known to fall in patches, at some part of the world, almost every year. Some curious showers, however, are not so easily accounted for. About 20 years ago a part of the famous great shower, which fell at San Jose, California, was sent here for examination, and proved to be the intestines of a chicken.

Prof. Davidson made some remarks on Dr. Dall's theory of the non-existence of the Japanese current in the Behring's straits. We give his remarks in another column. Messrs. Krauss, senior and junior, sent by the Bremen Geographical society to explore the Siberian peninsula and study the country of the Tchoukchees, were presented to the Academy, and a hearty welcome was extended to them. These eminent naturalists are awaiting some conveyance to the field of their researches.

A crustacea resembling a young lobster, taken in the open ocean 900 miles southwest of San Francisco, was presented by Capt. John O. Ladd, who preserved it for the Academy. Upon examination it was found not to be a lobster, but an interesting specimen of another animal.

NET GAIN.—While in the banking house of Ridout, Smith & Co., Saturday, says the Oroville Mercury, we saw 1,000 ounces of large, coarse gold, taken from the Roberts & Kendall mine, situated one mile and a half from Forbestown, in what is known as Garden Ranch Flat. This was the result of a four-months' clean-up, and was valued at \$17,500. The cost of water and the necessary expenses in running the claim during that time was \$6,300, leaving a net gain of \$11,200. Some time ago the owners were offered \$18,000 for the claim, and came very near taking it, but now would not take double that amount. The gentlemen have plenty of pay dirt in sight, and lots of water, and will return to make another run.

A STAMP mill is being built in San Antonio canyon, near Pomona, Los Angeles county.

## Copper Smelting—Its History and Processes.—No. 6.

[By HENRY HUSKEY VIVIAN, M. P.]

The first difficulty is got over at Mr. Lambert's works by using a muffle calciner heated by the waste heat of the smelting furnace; but when we consider the varying intensity of the heat given off at different periods of the ore-furnace charge, ranging from almost none at all at the period of skimming and charging up to the highest temperature during the melting process, I cannot doubt that much irregularity must occur in the calcining process which must militate against the regular working of the chambers, especially when joined to the inrush of atmospheric air when the calciner doors are down for stirring. I have seen the muffle calciners at Mr. Lambert's, and have read his evidence and that of Mr. Fenwick Allen, the manager of Messrs. Newton Keates & Co.'s works in Lancashire, where, as well as at the St. Helen's works, muffle calciners are used, heated on the Siemens system. Unfortunately, neither of these gentlemen goes fully into the question of the profitable working of muffle calciners; but I think I am justified in saying that they do not appear in several respects to give results equal to the Gerstenhoffer system. In Mr. Allen's answer to question 11,646 of the Noxious Vapors Commission, he says: "We diminish the escape by condensing the whole of the acids given off in the calcining process, and at the very outside it would be from 30% to 40% of the total sulphur given off in our works." I should have been glad if Mr. Allen had been able to give the committee, as I did, an accurate debtor and creditor account of the whole of the sulphur which entered the works. Again, he was unable to inform the Commission (11,660) what the percentage of niter used at his works is; but he says generally (11,658) that the gases are very dilute, and that they require three times as much niter as in ordinary kilns; and he also says (11,657) that the sulphuric acid costs 5s. more than if made from pyrites bought and burnt in kilns. Mr. Lambert's evidence as to the results of muffle calciners is even less favorable. I think I have now pretty nearly exhausted the subject of calcination, and may proceed to smelt my ore.

In considering the question of melting the calcined ore, I think we ought, in the first instance, to pass in review the two systems of reverberatory and blast-furnace smelting—"South Wales against the world!" Each system has its advantages and disadvantages. Let us weigh them.

### The Blast Furnace

Is slightly, very slightly in most places, more economical in the cost of fuel, and it undoubtedly, and in all cases, produces a cleaner slag; but its working is much more complicated, and it has a constant tendency to reduce the oxide of iron contained in the calcined ore into metallic iron, and thus to produce a mass of infusible matter at the bottom of the furnace, which, in no long period, causes the entire or partial destruction of the furnace, according to the arrangements made beforehand to extract it. Even in the best managed continental works, I have positive proof that these so-called "iron sows" are produced; in fact, they are an almost unavoidable incident of melting calcined copper ores in blast furnaces, especially high blast furnaces, owing to the partial reduction of oxides of iron by the ascending carbonic oxide before it reaches the melting point, where it would be able to combine with the silica, which we must assume has been provided for it. It has, I am aware, been proposed to get over this difficulty by taking off the gas a few feet above the melting point; but no great success can have attended this, from the fact that "iron sows" are still produced in considerable quantities in the best managed continental works. Another great drawback to the use of the blast furnace is, that it can only treat a comparatively rough mixture; much fine ore would soon cause it to "gob" or choke. The consequence is, that resort is had to slags to keep the furnace open, if rough ore cannot be obtained, even if the slag does not require remelting. I know of a case in which thousands of tons of slag are thus uselessly melted. When lead ore is melted in blast furnaces, it is possible to agglomerate it in the calciner so as to cause the furnace to "drive" well; but copper ore would require so high a temperature to agglomerate it, when sufficiently calcined, that it would be more economical to carry it a trifle farther and melt it in a reverberatory furnace at once. In blast furnaces, for the above reasons, I doubt whether ores could be dealt with, as they arrive from all quarters of the globe, varying enormously in their constituents and characteristics. Nothing in reverberatory copper smelting needs greater care than the formation of a proper mixture for the ore furnace; but the problem becomes vastly more complex if the ore furnace be a blast furnace.

I said that the blast furnace uses less fuel than the reverberatory. Roughly, I believe, the case stands about as follows: A blast furnace uses from 15% to 25% of coke, calculated on the quantity of ore smelted, according to the nature of the ore and the furnace; take it at 20%. A reverberatory uses, say, 45% of coal; but coke is about 2½ times more costly than coal, therefore the expense of the blast furnace would be as 50 to 45 of the reverberatory. If steam power is used for the blast, it makes the case of the blast furnace so much worse, unless the waste gases can be utilized to generate steam; but if fuel has to be transported to a distance, although the freight on coke is more than on

coal, the balance may slightly incline in favor of the blast furnace.

I also said that a blast furnace produces a cleaner slag than a reverberatory furnace. I believe that such is invariably the case, owing to the higher temperature at the melting point, which causes the slag to be more fluid, and thus permits the heavy regulus to pass more easily through the slag; the deep well of the blast furnace also assists in the last named effect. I estimate the difference between blast-furnace and reverberatory slags to be about 1% equal in money to about 3s. per ton of ore. As to the item of wages, I cannot speak positively, because so much must depend on the nature of the ore and the furnace; but in all cases with which I have had to do, the blast furnace cost is in excess of the reverberatory. There is one other considerable disadvantage in smelting in a blast furnace, namely, that from the same calcined ore a reverberatory furnace will produce a much richer regulus than a blast furnace; the former is an oxidizing, the latter a deoxidizing furnace. During the exposure of the ore on the bed of a reverberatory furnace, calcination goes on continuously, sulphur and the sulphuric acid partially formed in the previous calcination passing off. We found, on careful trial, that during the smelting of calcined ore in the ore reverberatory furnace, 13% of the original contents of the ore in sulphur were driven off. I have no similar data as to what sulphur is driven off in the blast furnace. The smoke issuing from blast furnaces proves beyond doubt that some is sublimed; but from the deoxidizing condition of the furnace, all the sulphates must be reduced, some to sulphurous acid probably, and some to sulphide of copper. As a fact, blast-furnace regulus is always coarser than reverberatory regulus, which means that more expense has to be incurred in the subsequent processes.

### The Reverberatory Furnace

Is a simple and easily worked furnace, forming no metallic bottoms until the copper stage is reached, and capable of dealing with all ores, as Ulrick Frosse found out 300 years ago. Whether calcined ore is melted in blast or reverberatory furnaces, the same results ensue, namely, the earthy matters (chiefly silica) originally contained in the ore combine with the sesquioxide of iron to form a slag, while the sulphur, purposely left in the calcined ore forms sulphides of iron and copper, which, being of greater specific gravity, sink through the slag, separating themselves more or less completely from it, according to the nature of the slag and the temperature at which it is melted. For this cause, the copper smelter must be careful so to combine his ores as, on the one hand, not to form too stiff or quarry quartz, a slag which hinders the operation of melting, and prevents the regulus from sinking freely through it; and on the other hand, too heavy a slag, which, while it may melt easily, is so nearly of the same specific gravity as the regulus as to cause the separation to be imperfect on that account. He must also be careful not to produce too rich a regulus, because the perfect separation of regulus and slag is next to impossible, and each prill of regulus which remains mechanically suspended in the slag carries with it more copper if rich than if poor. As I think I before said, we do not like to push our "coarse metal" or ore-furnace regulus beyond about 33% of copper; it contains about 23% of sulphur, and the remainder iron, arsenic, and other impurities, resulting from the original ore. I see Le Play gives "coarse metal" as containing 29.2% sulphur. According to our experience, it does not usually contain more than 23%. The ore-furnace slag consists chiefly of silicate of protoxide of iron and silica in suspension. Dr. Percy's concluding observations as to the reactions which take place in the ore furnace are concise and clear; anyone who desires to study them in detail can do so by referring to the 345th page of his work; indeed, the whole of the chemical changes which occur in copper smelting are set forth with admirable terseness and precision.

(TO BE CONTINUED.)

It is stated that the Denver and Rio Grande Co. has expended more than \$50,000 in importing laborers to work on the construction of its line. Large numbers, after being obtained from a distance at great expense, desert almost as soon as they reach the road and make for the mining camps, tempted by the prospect of getting rich in mining. This difficulty has induced the company to inaugurate a plan for importing several thousand trained workmen, together with a corps of engineers, from France. The company has had agents in Norway, Sweden and Italy, but they have not had much success in the first named countries, although the agent in Italy has secured nearly a thousand men, who will shortly arrive. It is believed that they will have greater success in France, yet it is considered doubtful whether the 10,000 men they desire can be obtained as rapidly as they are needed.

THE SULPHUR BUSINESS.—C. D. Rhodes, superintendent of the Humboldt Sulphur Co., informs us that they are now shipping 50 tons of refined sulphur from the mines to the railroad every week. Alex. Wise has four teams hauling the brimstone from the refinery works to the railroad, at Humboldt house, and they cannot take it away as fast as it is refined. They have found a large body of sulphur in the mine, and can keep the refining works running steadily without any trouble.—*Silver State.*

New quartz finds on the north fork of Flat creek, Shasta county.

## Electric Light in Mines.

[Read before the American Institute of Mining Engineers by OTTO A. MOSAS, Menlo Park, N. J.]

### On the Applicability of Edison's System.

The necessity for a more perfect safety-lamp than Davy's was announced by Sir Humphrey himself, in a paper read before the Royal Society, in which he first describes his beautiful deduction from studies on flame. He says: "If it be necessary to be in a part of the mine where the fire-damp is explosive \* \* the workmen may be lighted by a fire made of charcoal, which burns without flame, or by the steel mill, though this does not afford such entire security from injury as the charcoal fire."

This acknowledgement contains a germ of prophecy. Had the immortal discoverer of the arc electric light and the safety-lamp lived till now, he would have seen the fullest fruition of his scientific and philanthropic hopes combined in one invention, which I will take pleasure in showing you to-night.

Those of us (and I recognize many among you who have guided your steps by the "blende") who have been dazzled, soiled, confused and distracted by the flaring lamp, hung on the breast, head, or thumb, know how great the want, and have been frequently reminded of it while picking our devious paths over heaps of debris, or while examining the face of new and important cuttings. There are many here who, besides this discomfort, have felt the presence of the spirit of death burning blue in their lamps, and who, perhaps, have seen it fly heavenward from the shaft's mouth, bearing the souls of men.

The problem before us, which I will state as briefly as possible, is to obtain a mine lamp which will fulfill all the following conditions:

1st. It must be free from danger, in its use and presence, both to master and man; for it should be an axiom with the mine owner that his first duty is to consider the safety of the employee.

2d. It should afford an abundant, clear, white and penetrating light.

3d. It should not heat the air, nor render it impure.

4th. It should be perfectly reliable as a source of light in all varying conditions of the atmosphere.

5th. It should be available as an instantaneous danger signal.

Before describing Edison's lamp it may be well to enumerate, in the order of their introduction, the systems which are or have been in general use, or which have been suggested, and to fairly state their advantages and disadvantages.

1st. The open light of various forms, more or less protected, and burning oils and fats. These lamps, in mines free from fire-damp, have only found favor on account of their cheapness. They are offensive in odor, insufficient in illuminating power, and in use most inconvenient. Preserving the forms of antiquity, they are their own index of the want of progress in this important implement of the mining art.

2d. The phosphorescent lamp, containing substances luminous after exposure to sunlight, which we have recently seen revived by certain visionary inventors, was suggested by Davy, who before deciding to employ the wire-gauze envelope for his safety-lamp, experimented with Cantor's phosphorus. He does not do more than merely mention this method as being unworthy of adoption.

3d. The Davy safety-lamp and its congeners, which have found general employment wherever there exists a danger of explosion. It is very safe, provided the light is kept low (say to one-half candle), and is not allowed to raise the surrounding gauze to a red heat, and further, that it be not exposed to currents of air. But as these conditions are just such as exist during the times when most light is required, it is sadly wanting in essential particulars.

As modified by Museler and others, who substitute glass for the wire gauze immediately around the flame, it has been much improved, so much so that in Belgium it has been entirely superseded by Museler's lamp, although in England the weight of Davy's name and the prejudices of a solid gratitude have combined to keep it in general use. This lamp may still be employed as a fire-damp indicator, but more perfect ones, such as Ansell's, may be used automatically and in connection with a better system of illumination.

4th. The fluorescent lamp, probably due to Reitingler, was first practically applied by Dumas and Benoit. It consists of appropriate Geissler tubes set aglow by a continuous flow of sparks from an induction coil. Were the light of this lamp stronger, it would possess many of the advantages of Edison's, but, since from careful measurements made by Bergrath Lotner, it would take at least 25 of them to equal a standard candle, it will scarcely ever find employment except in localities rarely visited, or attract attention except as a scientific toy.

5th. The hermetically sealed voltaic arc light, has been employed by De la Rive, though it was first suggested by Louyat and Bouscain-gault. He proposes to use a hermetically sealed balloon containing two carbon points, a portable pile, and copper wires sealed to the balloon inclosing the carbons. Mechanical difficulties prevented this system being tested.

6th. The voltaic arc has been used as a source of light in open pits and other workings adapted to utilize its enormous concentration; but even when subdivided its application is extremely limited.

7th. Finally, there remains for consideration Edison's electric light, one that combines all desiderata, and supplies the requirements of the mine owner in practical and economic form. Edison's 16-candle power lamp is too well known to need description, but I will show you some modifications intended for mine illumination. Mr. Edison makes what are known as whole, half, third and quarter lamps, which are, respectively, of 16, 8, 5½, and 4-candle power. The electro-motive force employed in his system is standardized at 110 volts, and his lamp at 120 ohms resistance. Such a combination yields him a 16-candle power lamp in multiple arc, giving the light of an ordinary gas-jet. It is intended for domestic purposes, but is far too powerful for the necessities of the mine. An arrangement in which four quarter lamps, of 30 ohms resistance each, are nited in series, answers admirably.

The method to be adopted in applying the Edison light to mines is very simple. Wires run direct from the dynamo-electric machines to the different workings, supplying light to the shaft on their way. Each lamp, if desired, be immersed in water, or be protected from fracture by a coarse wire screen. The connections can be all made under water, and thus lamps may be put in or out of circuit without the slightest danger from the electric spark.

## San Bernardino Mineral Districts.

Lytle creek is the first creek west of the Cajon pass, in the San Bernardino range, and empties into the Santa Ana river. Numerous placer mines have been located and worked for nearly 30 years, but never with such promise of success as at present.

The Mohave gravel mines are located in Holcomb valley. This deposit of placer gold is 40 miles northeast of San Bernardino, at the headwaters of the Mohave river. A great many locations have been made, and prospectors are now making \$3 to \$5 a day in panning.

The Bear valley mines lie four miles east of Holcomb valley. The mines of this district are gold quartz, free milling ores occurring in large deposits. A 40-stamp mill was erected, and a failure made for lack of proper management.

The Lone valley mines are 12 miles east of Bear valley and 90 miles northeast of San Bernardino, by wagon road. There have been about 60 locations made in this district. The ores are mostly smelting, galena and carbonates; veins large and extensive.

The Black Hawk mines are located 80 miles northeast of San Bernardino and four miles north of Bear valley, on the east foot of the Sierra Nevada range. About 30 locations have been made. The ores are smelting, galena and carbonate of high grade.

Dry Lake district is 90 miles northeast of San Bernardino; gold and silver ores of high grade; 32 locations.

New York district is about 40 miles west of the Colorado river and north of the 35th parallel survey, also about 40 miles southeast of Ivanpah. There are eight large veins of silver ore in this district; average width, 4 to 12 ft., with large bodies of good ore which works from \$40 to \$60 per ton. These ores are rebellious and require roasting.

Alvord district is 100 miles northeast from San Bernardino, and 10 miles north of Hawley's station, on the Mohave river. Here the gold is found in a large vein of jasper, which assays from \$10 to \$120 per ton. Analysis by John T. Reed shows gold, iron, aluminum and quartz.

Ivanpah, the oldest and most thoroughly developed district in the county, lies 190 miles northeast from San Bernardino. The mines of the district yield milling ores of high grade, and have produced large quantities of silver bullion. The veins are small. There are two 5-stamp mills in the district.

Mohave district is 75 miles northeast from San Bernardino, on the eastern foot of the Sierra Nevada range. These mines are galena and carbonate, and assay \$16 to \$60 silver, and 30 to 50% lead.

Grape Vine district is 75 miles north of San Bernardino. The ores of this district are silver ores, horn silver and native silver. The vein matrix is sulphate of barata. A great many locations have been made in this district.

Calico Mountain district, situate seven miles from Waterman's mine, shows the same character of ore, low grade on surface, and assays from a trace of silver to \$240 per ton. The ledges are from 4 to 50 ft. in width.

Ord district is 70 miles northeast of San Bernardino. The ores of this district are principally gold, of rather low grade, but free milling. Pincarte District, 26 miles south of San Bernardino, was located May 14, 1880. Blind leads of free gold are the rule.

The Temescal tin mines are 30 miles south of San Bernardino, at the base of the Eastern Twin Peaks. They have been opened to a considerable extent.

Silverado District is 45 miles southwest of San Bernardino; ledges from one to three feet in width, bearing northeast, southwest; ore rebellious, and requires roasting.

San Antonia district is 30 miles northwest of San Bernardino. The placer mines of this district have been worked at intervals for many years, and have produced large quantities of gold.

The new mines in Silver Mountain district, 50 miles north of San Bernardino, and from 10 to 15 miles west of the Point of Rocks, on the Mohave river, are all recent discoveries.—*Cor. San Bernardino Times.*

MECHANICAL PROGRESS.

Spence's Metal.

We have already described in these columns the peculiarities and special advantages of Spence's metal in connection with the various purposes to which it is applicable. Notwithstanding the doubts with which it was at first received, we learn from our English exchanges that, although only a little over a year has elapsed since attention was first directed to this remarkable substance, it has already come largely into use for an infinite variety of purposes, both industrial and artistic. Actual experience has now shown its economy and efficiency, as attested by the highest authority. The English technical journal, *Iron*, says that amongst other uses to which the metal can be applied may be mentioned the following:

As a substitute for bronze, lead, type metal, zinc, carved marbles, and materials used in capuling bottles, in all of which cases its use is stated to be accompanied by a saving of from 50 to 80%, the figures being thus based upon actual practice, and the metal being used by several governmental departments, by the Metropolitan Board of Works, and by various public companies. Amongst the advantages possessed by Spence's metal we may refer to the following:—Its low melting point, its resistance to atmospheric or aqueous influences, its insensibility to the action of acids, its close resemblance to the antique bronze, its producing an exact impression of the mold, thus saving the labor of chasing; its extreme lightness, being half the weight of most of the metals in use and its cheapness.

No wonder, then, that with so much in its favor, its development in the industries and the arts has been so great that extended manufacturing facilities have become necessary. To this end a company has been formed under the title of "Spence's Metal Manufacturing Co., Limited," with a capital of £200,000 for the manufacture and sale of the metal. The company will acquire the lease of a piece of ground at Belvedere, on the Thames, where will be erected a manufactory, buildings and machinery sufficient to enable them to turn out 100 tons per week of the metal, and provision will be made for the further extension of the works if necessary. Pending the completion of the new factory, the metal will be produced at the present works. Mr. J. Berger Spence will take the position of managing director. With all these things in its favor the success of this metal in the future will probably bear no comparison with that of the past, great as that has been.

New Application of the Link-Belt.

The varied and far-reaching applications possible to a new and valuable invention are rarely seen at the outset, but develop from time to time, as the employment of the device becomes more general and wide-spread. The growing application of the link-belt is no exception to the this rule. This invention, which has long proved very useful in many ways, has recently found an entirely new application—to the propulsion of stern-wheel steamboats. In the past there has been no transmitting agent that would stand the exposure incident to driving the paddle-wheel of a stern-wheel steamer except the enormous beam, which must be duplicated, and, of course, with two engines occupying a large amount of space and weight of material by reason of the peculiar duty to be performed and slow motion required.

During the past year an enterprising firm in Chicago has substituted the link-belt for the beam, which device allows the engine to be placed nearer to the center of the boat, requires but one engine, and that of small size, by reason of the increased speed which can be employed. By this device a comparatively small engine may be employed, as simple as an ordinary sewing machine, and yet of sufficient power to drive the largest of the class of steamers alluded to.

Another important advantage gained by use of the belt is the facility with which the floats of the paddle wheel may be adjusted to the varying draft of the boat; for the wheel is so mounted that it may be readily raised or lowered bodily, even when in motion, without any derangement of the machinery. The vast number of uses to which this improved elevating and conveying device may be put, and its great capacity as a labor-saver in mechanical industry, is securing for it a most favorable reception among progressive mechanics everywhere.

**SECURING GLASS IN SKYLIGHTS AND ROOFS.**—A recent English patent shows what seems to us a very convenient and reliable way of fastening sheets of glass in skylight frames of either wood or iron. In the case of a wooden rafter a piece of sheet lead is cut three and one-half times the width of the rafter, laid across the rafter, projecting equally on either side, and nailed at intervals. The lead is then doubled back over the heads of the nails to the center of the rafter on either side and turned up at a right angle. The glass is then laid and the lead turned down over the face of the glass so that when finished the lead covers the glass the same width of the rafter. If T iron is used for a rafter the lead is doubled under the edge of the T instead of nailed, as in the case of wood, and in all other respects handled just the same as with wood.

Malleable Cast Iron.

In a paper read by M. Fourquignon before the French Academy of Sciences on malleable cast iron, he states that, as a bar softens, one observes throughout the mass an abundant deposit of amorphous graphite. Matters stand thus when the bar lies in an inert mass, as in anthracite coal; but when the pig iron comes in contact with a substance capable of burning or absorbing the carbon, a secondary reaction sets in. The liberated carbon having disappeared from the superficial zone, the equilibrium determined by the heat undergoes a slight change. A portion of the graphite from the lower strata returns to its combination, and ascending to the surface, disappears, and is replaced in its turn by another. The phenomenon continues until the average composition of the bar corresponds to a certain minimum of carburization of the iron, varied according to the circumstances of the annealing process.

A proportion of manganese, even below 5-1,000 gradually arrests the softening process until it ceases altogether. The pig, of course, continues to lose carbon by oxidation, almost as much in fact as when it is pure, but the manganese resists the production of graphite and retains it in combination in the metallic mass. The silicon may, to a certain extent, saturate the manganese and drive out the graphite. He finds these explanations based on the following facts, as elicited in the course of his experiments: (1.) Pig iron which is truly malleable always contains graphite; (2.) pig may lose carbon, and yet remain brittle if graphite be not formed, or if the quantity existing before the annealing process be not augmented; (3.) pig may become malleable without losing a sensible portion of its total carbon, the annealing being effected by the medium of coal, the co-operation of an oxidizing agent not being indispensable to the softening process; (4.) if silicon be added to a manganiferous pig the metal is improved by annealing.

Hollow Steel Shafting.

Hollow steel shafting is quite a new idea, and seems to be coming into quite extensive use in England. Specimens shown at the recent Manchester (Eng.) Exchange are said to have created quite a sensation among the iron and steel men. A large iron firm in Pittsburgh, Penn., have experimented some in this direction, and are now prepared to make this a specialty. In a recent communication to the *American Manufacturer*, they say:

"Casting hollow steel ingots for shafting and pipes will be one of our specialties in our new Bessemer plant, and we claim, and think we can prove, that we were the first to cast hollow steel shafts and pipes which could be rolled as other steel or iron is rolled.

"We will, within a few days, cast a steel pipe 16 ft. long, 14 inches diameter outside, and 10 inches inside, weighing 4,500 lbs., which could easily be rolled to 40 ft. in length.

"Nearly two years ago we tried to interest two of our largest pipe manufacturing firms in rolling steel pipes, but without success."

"We will run our new plant on heavy castings, and shaped steel ingots for channels, beams, angles, hollow shafts, and any work which cannot easily be shaped with rolls.

"We intend to pay particular attention to making these special steel ingots of low or high carbon, of ordinary Bessemer or of refined Bessemer, made under our own patents."

**THE REESE FUSING DISK**, to which quite full allusion has been made in these columns, seems to have attracted considerable attention in England, and one party, at least, has undertaken some experiments to determine its practical utility. The results of those experiments, with illustrations, were furnished to *London Engineering*, from which journal they were copied into the *Scientific American*. The conclusions were anything but favorable to the practical value of the invention. In a subsequent number of the *Scientific American*, the inventor, Mr. Reese, appears with a communication, in which he says: "I have written *Engineering* that the statements made in the article are so astonishing, and the work exhibited is so radically different from any that I have ever seen produced by the fusing disk, that I think the gentlemen who furnished the article and cuts and made the statements contained in the article have made a mistake, and I asked for their address that I might give them attention first." Mr. Reese further reiterates what he has heretofore said and claimed in regard to his invention, and expresses his willingness to explain and maintain his theory, and cheerfully accept the result of the discussion, whatever that may be.

**AN ELECTRIC SOLDERING IRON.**—Mr. Ball, of Philadelphia, has patented a soldering-iron capable of melting the hardest solders, as those of gold and silver, by electricity. The electrodes pass through and project beyond the handle, and are connected with a ball of platinum; this, when battery connection is complete, becomes heated to any required degree, and the desired soldering is readily effected.

**A NEW STEAM BOILER.**—A new form of steam boiler, invented by Mons. Bernard, has been tested on a French vessel with such satisfactory results that the naval authorities in France have directed a careful examination of it, with a view to its adoption for war steamers. It is shaped like a gasometer receiver, and its chief advantage over other boilers is said to be superior economy in the consumption of fuel.

SCIENTIFIC PROGRESS.

Phenomenon Presented by Vortex-Rings.

Our readers are all familiar with the peculiar appearance of vortex-rings, as they frequently result from the discharge of cannon or from the sudden discharge of steam through an open top locomotive stack. Professor A. E. Dolbear, of Tufts's college, Mass., has been making a careful study of the peculiar phenomenon, connected with these rings, and to facilitate his study has improvised a very simple apparatus for their production, which may easily be constructed by any person who may be interested in this curious study. We copy from *Science*:

1. If one vortex-ring strikes another vortex-ring upon the edge the two rings will bound away from each other as though they were solid elastic bodies, each one vibrating as it recedes.
2. If one vortex-ring overtakes another ring, both moving in the same straight line, and both are of the same size, then the forward one will expand in diameter, and the latter will contract in diameter and will go through the forward one, when each will return to its original dimension. At the same time the forward one will have its velocity retarded while the other will have its velocity increased, and it may overtake the forward one and go through it.
3. If a vortex-ring passes near any light object, as, for instance, a silk thread suspended, or better still a small cloud of smoke or ammonium chloride dust, the latter will be seen to be apparently repelled from the front of it, but attracted and drawn into the ring from the rear.
4. If a vortex-ring be projected parallel with any surface, and at not too great a distance from the surface, the ring will move in a curved path toward it and strike it.
5. If two vortex-rings are projected so as to start in parallel lines near to each other, they

will approach each other until they touch, when they may be either broken or else bound away from each other as in the first case above.

6. If two vortex-rings having the same rate of rotation be started in lines parallel to each other, and at not too great a distance apart, they will not only approach each other, but they will combine to form one ring, which continues to move in the same direction.

7. The combination is effected by the breaking of each at the point of contact, and the welding of the opposite parts of each ring to form one ring with twice the diameter.

8. These rings may in like manner be combined into one.

9. The structure of the vortex-ring is concentric, that is, a cross section of a ring generally shows a series of several concentric circles, with a hollow center. The middle of the ring appears to be a cylindrical unoccupied space.

As experimental work with such rings is very entertaining, as well as suggestive of the behavior of the real atoms of matter, it may be well to give the simple instructions necessary to perfect success.

Provide a cubical box with dimensions about a foot each way, having a swinging back frame, over which is stretched a piece of stout cotton cloth. On the opposite side, two or more inches may be bored two inches apart. Pour some strong hydrochloric acid into one saucer, and some strong ammonia water into another. Set the two into the box, and shut down the door. The box will at once be filled with the white fumes, and a tap with the finger upon the cloth back, will send out well formed rings.

The phenomena one to five, can best be seen by employing only one of the holes, so as to form but a single ring. By striking the cloth a little harder the second time than the first, the second ring may be made to overtake the first, and if it is desirable to exhibit the rings to a room full of people, there should be but a single hole in front, and that one about three inches in diameter; the rings can then be projected with force enough to make them go 10 or 15 ft. from the box.

The other phenomena can best be studied by using only small holes, and tapping gently. The rings will come together within a few inches of the box. It seems to be essential that the two rings that combine, should have the same rate of rotation, a matter easily secured by forming the two at once in the above described way, but well nigh impossible, if one is formed after the other.

It is sufficient now to remark that the new phenomena described above, stimulate in a very striking way, what we call gravitation and chemism.

ON HIS FOURTH HUNDRED.—Mr. Edison took out his 301st patent on the 12th of March.

Photosphonic Discoveries.

At the meeting of the National Academy of Sciences, April 21, Prof. A. Graham Bell read an important paper describing at great length the recent investigations made by Mr. Tainter and himself in the field so brilliantly opened by them a year ago. After referring to their earlier observations on the production of sound by radiant energy, Prof. Bell said that at his suggestion and during his absence in Europe, Mr. Tainter had pursued the investigation of the sonorance of matter under the influence of radiant energy, employing a vast number of substances inclosed in test tubes in a simple empirical search for loud effects. He was thus led gradually to the discovery that cotton-wool, worsted, silk, and fibrous materials generally, produced much louder sounds than hard rigid bodies like crystals or diaphragms, such as had hitherto been used.

Mr. Tainter next collected silks and worsteds of different colors, and speedily found that the darkest shades produced the best effects. Black worsted especially gave an extremely loud sound. As white cotton wool had proved itself equal, if not superior, to any other white fibrous material before tried, he was anxious to obtain colored specimens for comparison. Not having any at hand, however, he tried the effect of darkening some cotton wool with lamp-black. Such a marked re-enforcement resulted that he was induced to try lampblack alone. About a teaspoonful of lampblack was placed in a test tube and exposed to an intermittent beam of sunlight. The sound produced was much louder than any heard before. Upon smoking a piece of plate glass and holding it in the intermittent beam, with the lampblack surface toward the sun, the sound produced was loud enough to be heard, with attention, in any part of the room. With the lampblack surface turned from the sun the sound was much feebler.

**ENEMIES OF SPIDERS.**—The well known naturalist, the Rev. H. E. McCook of Philadelphia, has been talking to the academy of that city on spiders, which he designated as the most benevolent of insects. Among the principal enemies of the spider he enumerated many of those hymenopterous or four-winged flies, the bees, wasps, etc., which produce flesh-eating grubs. Large numbers of spiders are used by these species as food. The nest of one of these forms was exhibited, built of clay in such a manner as to resemble the pipes of Pan. When opened these nests were found filled with spiders of different species. They were all paralyzed by the fly, but not killed, and in this state of suspended animation they remain until the hatching out of the grubs, which eagerly devour them one after the other. The unfortunate captives lie limp in the jaws of the grubs, showing no signs of sensation, and making no resistance whatever. Other flies, and among those, may be included the common black house-fly, prey upon spiders by destroying the cocoons, or by sucking the contents of their eggs when they happen to be uncovered or only slightly protected. The eggs are also devoured in large numbers by birds. Some species of birds assist in preventing the spread of spiders by making use of their webs, especially the thicker portion used in the construction of cocoons, to build their nests. A nest was exhibited, composed of this mineral in such quantity as to indicate the destruction of a great many webs. Those hymenopterous insects which deposit their eggs in the cocoons of the spiders are, however, their most destructive enemies. When the grubs are hatched they attack the eggs and young of their hosts, and consume them as food until sufficiently developed to obtain their nourishment.

**THE RELATION OF THE ATOMS OF CHEMICAL ELEMENTS TO ELECTRICITY.**—Prof. Helmholtz, in his recent Faraday lecture, affirms that the atom of every chemical element is always united with a definite unvarying quantity of electricity. This quantity stands in close connection with the combining power of the atom, or its quantivalence. If the amount of electricity of the monad atom be taken as the unit, that of the dyad is two, that of the triad three, etc. Prof. Helmholtz says: "If we conclude from the facts that every unit of affinity of every atom is charged always with one equivalent either of positive or negative electricity, they can form compounds, being electrically neutral, only if every unit charged positively unite under the influence of a mighty electric attraction with another unit charged negatively. This ought to produce compounds in which every unit of affinity of every atom is connected with one—and only with one—other unit of another atom. This is, indeed, the modern chemical theory of quantivalence, comprising all the saturated compounds."

**TO DISTINGUISH AMBER.**—Some of the ways of distinguishing amber from copal are thus given in *La Nature*: "Copal is yellow, of a more or less deep tint, but uniform throughout, and has yellow points like sulphur on its surface. Amber in a fragment of 12 centimeters in length will show a variation in shade. Amber when rubbed will yield a strong aromatic odor; its imitations will not. Amber may be bent after being smeared with tallow and heated; the imitations will not bend. Amber may be cut, sawed, rasped or polished, but cannot be cemented or soldered like copal. The density of amber is 1.09 to 1.11; that of copal is 1.04."

PATENT COKE, imported by Balfour, Guthrie & Co., from Wales, is used at a number of places here, and in Utah, Nevada and Arizona, the Copper Queen company, in the latter Territory, using it for smelting their ores. The Selby Lead Company, Union Iron Works, Risdon Iron Works and others in this city use only this kind of coke. The importers advertise it for sale in quantities to suit.

Just as we go to press we receive a copy of "Copp's U. S. Mineral Lands," of which we will speak more fully after having examined the book, which is a full and complete one, containing laws, forms, instructions and decisions.

The Day S. M. Co. has now full management and control of the Mendha and Hillsdale mines and the Hillsdale furnace.

## MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertisements in Mining and Scientific Press and other S. F. Journals

## The Mining Share Market.

The stock market is rather quiet, as is the news from the mines. Our tables give the fluctuations in price. The most interesting thing which has occurred in stock circles is the dismissal of the Burke bonanza suits, by Burke's consent. One Chrystal, however, objected, and the lawyers were called upon to show cause why the dismissal of the suits should not be set aside, on the ground of fraud and collusion. Chrystal's lawyer said that Mr. Burke, as a one fifty-four hundredth part of a legality (the Consolidated Virginia M. Co.), had no more right to make terms with Mr. Flood for the dismissal of three half-won suits than any other owner of 100 shares of Consolidated Virginia. Mr. Burke, said counsel, has never claimed that one dollar nor one cent was due him. How, then, did they arrive at a basis of settlement? Mr. Van Ness supported his position by numerous authorities, and spoke for two hours. Burke has commenced another action for \$12,000,000 against the Bonanza firm, and Chrystal has commenced one to recover \$32,000,000.

News from the Comstock, dated the 18th, is as follows: The water at the Jacket is out to within twenty ft. of 2700-ft. level. All the pumps are doing good work.

The section of heavy pipe for the east half of the hydraulic pump of the Combination shaft failed to arrive to-day. The west pump is now running smoothly six strokes per minute.

The Union shaft is seven ft. below the 2700-ft. level, and rock is growing softer and blasting better.

Work at the Sierra Nevada is still preparatory, and consists of cutting drains, repairing car-tracks and putting in turn-tables.

## Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports: Northern Belle, May 14, \$13,124.92; Bodie, May 16, \$7,293; Northern Belle, May 11, \$8,079; Eureka Con., May 12, \$3,690; from Pioche for week ending 14, \$4,249; Star Co., May 7, \$7,588; Teacup, May 10, \$2,700; Christy, May 9, \$2,936; Rebellion, May 9, \$1,893; Ontario, May 9, \$5,212; Ontario, May 11, \$4,880; Germania, May 9, \$2,730; Germania, May 10, \$1,710; Tintic, May 9, \$2,891; Horn Silver, May 11, \$7,500; Rebellion, May 11, \$2,511; Hanauer, May 10, \$1,710; Ontario, May 12, \$5,495; Horn Silver, May 10, \$5,000; Germania, May 10, \$1,600; Christy, May 10, \$1,332; Ontario, May 14, \$1,900; Nevada, May 14, \$1,950; Alice, May 12, \$21,536; Hanauer, May 14, \$1,900.

has been made for them, the books have never been found. Those books are in Picche and will be brought to light at the proper time.

### California Jaunts and Resorts.

Many of our readers may remember Black's charming story of the "Adventures of a Phaeton," in which the author takes his hero and heroines through the length and breadth of England, and describes in a very pleasant way the scenery they saw on the road. The dimensions of the State of California preclude the possibility of a trip which will include the whole scope of the State, unless more than one summer should be consumed. But, as there is no finer country in the world for summer excursions and camping out than this, a jaunt over a portion of it will suffice for most persons. One can, moreover, choose the kind of scenery he prefers, and, to a great extent, the climate also. The moist, cool atmospheres of the coast, the warmer and drier air of the mountains, or the heat of the valley, present a variety difficult to find elsewhere in this same area.

In summer we do not need, in our excursions, to count on rainy days. It never rains here during what is known as the "dry season." One can sleep in the open air or in tents for six or seven months in the year without inconvenience.

Tourists are somewhat apt to think that after they have seen Yosemite, Lake Tahoe, the Geysers, the Big Trees and a few more of the "sights" of the State they have seen it all. But there are many beautiful spots in California which lie off the route of travel, which are worthy of a visit. The number of "Springs," and other health resorts, has increased greatly of late; and there are now numerous camping grounds, where those who prefer camping out to hotel life will find all the necessary conveniences.

Going south from San Francisco on the peninsula there is a pleasant road from San Mateo over the hills, by Crystal springs, to Spanish town and Purissima creek, noted for the finest trout in the State, as they are perfectly pure, the creek falling over the cliffs into the ocean. Further on is San Gregorio creek, with its lagoon famous for fishing. There is a hotel here. Then we come to Pescadero, a coast town much frequented in summer and noted for its "pebble beach." The Pescadero and Butano creeks near by afford fine sport for the angler. Beyond that is Scott's valley, and then Santa Cruz, the well-known watering place. Between Purissima and Santa Cruz there are numerous creeks other than those mentioned, with plenty of fine hunting and fishing. Camping grounds will be found all along at many points.

Another trip, starting from this city, is to go by the railroad by way of San Mateo, Redwood City, Menlo Park, etc., to Santa Clara and San Jose, the beautiful towns in the Santa Clara valley. From the first, one may branch off to the foothills of the Santa Cruz mountains, where he will find Blackberry farm, Congress springs, and Los Gatos. From San Jose one may go to the famous Almaden quicksilver mines, and in the opposite direction, a beautiful ride is out to Alum rock, on Penitencia creek, and from there up to the summit of Mt. Hamilton, where the Lick observatory is being built. From San Jose, the S. P. R. R. carries its passengers down the valley past Gilroy (from where one may go to the Gilroy hot springs), through the San Juan pass into the Pajaro valley, and across to the noted watering-place of Monterey, where the railroad company has erected a magnificent hotel. There is the beautiful Bay of Monterey with its splendid beach running around from Monterey to Santa Cruz. At various points on the line of the beach are hotels, camping grounds, and various accommodations for tourists and campers. Aptos and Soquel are the most prominent points.

Back of Santa Cruz the range of mountains of that name offers a splendid opportunity for camping, fishing and hunting, and there are numerous public resorts and springs, such as Magnetite springs, Wrights' and others. The climate in the vicinity in summer is beautiful, and the mountains usually filled with campers.

Following on down the coast, we strike back through the Salinas valley to Soledad, and from here may visit the Pajaro springs, seven miles distant. Then continuing on down the valley again we meet the plateau on which is Paso Robles springs, a noted health resort. Then further on we arrive at San Luis Obispo, an old Spanish town surrounded by grain fields and sheep and cattle ranges. Between there and Santa Barbara these ranges prevail. Santa Barbara is on the coast and is usually reached by steamer and not by the route we have mentioned, which is the way one would have to go by wagon.

To see the coast and its towns below Monterey, the best way to do is to take one of the Pacific Coast Steamship Co.'s steamers and go as far as San Diego and back. In this way Santa Barbara may be visited conveniently. You can also stop at Los Angeles, and by lying over a trip, visit Santa Monica, the orange groves of Los Angeles, and vineyards of Anaheim.

Back from the coast is the charming city of Los Angeles, with its lovely environment. Beyond is San Gabriel valley, with the famous Sierra Madre Villa, popular far and near. By rail eastward one reaches the valley of the Santa Ana, and sees Riverside, a horticultural jewel, with the Glenwood cottages in the midst of orange groves. Beyond is the beautiful San Bernardino valley with the lovely Crafon retreat at its head, the Arrowhead springs,

with their medicinal waters and enchanting traditions, and Waterman's hot springs, which have wide fame but are not now open except for transient visitation.

Returning to the coast one may take the steamer and see San Diego with its magnificent harbor and splendid climate. Returning, as the steamer comes up it passes through the Santa Barbara channel, between the islands and mainland, and coasting along up, finally enters the historic portal of California—the widely-famed Golden Gate.

Starting again from San Francisco, as a center, going north along the coast, we visit Sausalito and San Rafael, and back of them Mt. Tamalpais, and borne by the North Pacific coast narrow-gauge road we pass through a beautiful country, up along the shores of Tomales bay, passing on the way Paper-mill creek, Taylorville, and many beautiful camping spots; then on through the redwood timber to Duncan's Mills and the Russian river, famous for its beautiful scenery.

Then again, by a route ending at the same place one may go by the S. F. & N. P. R. R., to Donahue, Petaluma, Santa Rosa (where you leave for Mark West springs), to Healdsburg, on the Russian river. From here Litton springs, Skaggs springs, the world-famous Geysers, etc., may be visited.

A beautiful trip is up through the fine vineyards of the Napa valley, where are hosts of summer resorts. In this county many pleasant summering places are established in the neighborhood of Napa City, St. Helena, Calistoga, Kellogg and other places. Among the well-known resorts are the Napa Soda springs, Litton springs, Nook farm, Sulphur springs at Calistoga, Etna springs near Pope valley, Sulphur Springs ranch near Knoxville, and Petrified Forest.

Entering Lake county from the west, the Highland springs, reached via the Blue lakes by stage from the railroad station at Cloverdale. Entering the county from the south, by stage from Calistoga, the traveler passes Mt. St. Helena, and can take a magnificent view from the summit by tarrying at the Mt. Toll House, and takes a short horse-back ride. Anderson springs, Harbin springs, Glenbrook, Adams' springs, Seiger springs, Howard springs, Soda Bay, on Clear lake, Sulphur banks and Borax lake, Mound cottage, Bartlett springs are among the notable attractions of Lake county. Lake county seems admirably and wonderfully adapted for a universal tourists' field, and is some day destined to attain a world-wide reputation.

Shasta county from the well watered bottom lands of the upper Sacramento valley up to the refreshing Strawberry valley at the base of Mt. Shasta, some 70 miles or more, is a pathway full of joy to the hardy tourists who delight in rugged walks of nature. The United States fish hatching establishment on McCloud river and Soda springs, clear fishing brooks and rivers, good fishing, etc., are here met with.

In Contra Costa county, the view from the summit of Mt. Diablo, in a clear day, is grand and wonderful in the number of cities and towns embraced in the vast extent of populated territory brought within the scope of the tourist's vision. At Byron, in this county, are hot sulphur springs which are lately becoming quite noted. The Piedmont springs in Alameda county, back of Oakland; the hay baths at Alameda; the sulphur springs in Colusa county, the White Sulphur springs near Vallejo, in Solano county; Wahler lake, Donner lake and hosts of other attractions might be mentioned.

The whole range of the Sierras, which extends the length of the State, abounds in magnificent scenery. It would take more than a page of our space simply to mention the points of interest. At different points in the range and the foothills hydraulic and quartz mining are carried on extensively, and those who have never seen the former should visit at least one gravel mine while in California.

It is of course impossible, in a brief article to enumerate all the pleasure and health resorts of California or all the thousand and one places where people go to amuse themselves in the summer months. We shall in future issues of this journal take occasion to mention other than those spoken of here. Every little canyon and glen, every mountain valley, every nook has its picturesque points, known to a chosen few. Here and there are places more widely famed. The vineyard regions of one section, the orange orchards of another, the wheat fields of another, possess charms to allure people of different temperaments. Others again prefer the solitude of the hills, where the unbroken forests reign supreme, where they can retire for a time from the hush of scenes of life.

In illustration of the grand rush of emigration from Europe to this country, a New York telegram furnishes the following startling statistics: The arrivals at Castle Garden during April were 60,000, about 1,400 in excess of the immigration during April of last year, and upwards of 4,000 in excess of that of May last, when 55,083 were recorded. This is the heaviest monthly immigration in the history of the port. From the 1st of January to date the total is about 105,000, or 25,000 more than were reported during the first four months of 1880. The steamship companies say they are advised by their agents in Europe that the exodus from there will be even greater in the coming month from all the North German and Scandinavian ports, and arrangements to put on extra vessels to provide needed accommodations have been made accordingly.

### The Placer Mines of the Klamath and Trinity Rivers.

Among the richest of the good paying placers of '49 and '53 were those of the Klamath and Trinity rivers. And while they are still worked with considerable profit by some of the modern methods, yet they are not operated to the extent which their real merit and worth would warrant, nor have they kept pace, in fact have fallen far behind, those of localities that are more easily approached. The first stages of placer mining passed with the pan and rocker with us as it did in other sections, with the introduction of improved methods, still, even with this we have seemingly kept in a kind of a rut which prevents any material progress in this industry, and thus the mining industry has languished for many years in this section referred to. Whatever may have been the amount and number of fortunes taken in gold dust from the Klamath and Trinity rivers, it is scarcely more than a mere prospect of what is still in deposit, awaiting the development of enterprising capital and engineering science. There are very many claims, particularly on the Klamath and Lower Trinity rivers, that are being held by parties who know well enough their value and perhaps the proper way to open them, but who, feeling unable or indisposed to take the risk, are "talking it easy," and, like Micawber, "waiting for something to turn up." That these mines have not kept pace with other sections is not owing to any doubt as to the wealth or availability of this deposit, for in this the well-developed quartz ledge offers no greater certainty, but it is due to three things, namely: 1st, their apparent isolation; 2d, lack of capital; 3d, want of engineering knowledge and business capacity. In speaking of the idea of isolation we emphasize the word "apparent," because we think that all there is of it. It is true that they cannot be nearly approached by railroad, but the principal provisions required are cheap, and the country is amply able to produce what will be required of it. Capital has not been seeking investment in this apparent isolation, because of the lethargy and almost oblivion that rests upon the country. Those who occupy it have made little or no attempt to let these possessions be known to the world, except in a few individual cases; no general or public means have been employed to advertise or throw the mines upon the mining market. But what we consider of equal, if not greater, importance than these, is the need of engineering experience and judgment, the capacity to plan and execute, the ability to calculate costs, results and effects. There are many of the benches, bars, and even the bed of the river itself, that will yield certain and rich returns, and do not require the outlay of very large capital, if directed by those having both practical and scientific knowledge. We have before suggested that the golden wealth in the beach sand was an incentive for inventive genius to perfect some machine to save the gold. This suggestion is in every way applicable to the high benches of the Klamath and Trinity. There are hundreds of them that are rich, but lack water. At their base runs the river with water in any amount inexhaustible, and in whose current is power enough to force this water to any reasonable altitude. He who shall invent a method of harnessing that power to the end of raising the waters of the Klamath on to the high benches along its course can command any fortune he chooses. And when the speed of the Klamath river is considered (for it is a rapid river), it really seems to be a feasible and practicable matter, and its accomplishment would be far less wonderful than the telegraph or the telephone. Of late some attention has been turned toward these neglected mining grounds by persons having the means to carry out necessary work. Some investments have already been made, and others are discussing the subject.—*Democratic Standard.*

### Mining Altitudes.

A good deal of nonsense is being indulged in by cotemporaries about the altitude at which mines, and especially silver mines, are found; and one paragraph, evidently started by a man from the Louisiana lowlands, says that "scientific men have proved by actual measurements that most of the great silver mines lie 10,000 ft. above the present sea level, and among the richest are some 2,000 ft. higher still." Joh. of the land of Uz, who was doubtless better versed in geology, mineralogy, metallurgy and practical mining than many of the editors who keep the above quotations afloat, said: "Surely, there is a vein for the silver, and a place for the gold, where they fine (refine and purify) it." Rich mines have been found as high as 16,000 ft., and many of them as much as 10,000 ft. above the level of the sea; but it does not follow that silver mines are found only at such altitudes. The highest croppings of the famous Comstock are considerably less than 8,000. The Eberhardt, of White Pine, Nevada, which was the richest silver mine in the known world, is barely 9,000 ft. above the sea level. The Carthaginian mines of antiquity, which at one time employed 40,000 operatives, were scarcely 5,000 ft. high, and the rich mines of Tombstone, Arizona, do not attain even so great an altitude. In all the broad mineral region of Nevada no paying vein of silver ore has been found at an altitude of 10,000 ft. It does not follow even that, because veins of silver are usually found in the older

rocks of lofty mountain ranges, they may not also be found in the sandstones and other sedimentary rocks of the valleys, as in the case of the vast rich regions of Silver Reef, Utah. The speculation as to the "altitudes of mines" is all nonsense, for "surely there is a vein for the silver," and that vein is as likely, all other conditions being favorable, to be at an altitude of 4,000 ft. or less, as at one of 10,000 ft.—*Bodie Free Press.*

### Raising Water from Mines.

A cheap, simple, and useful elevator for mines, which it is thought may in some cases obviate the use of the forms of elevator now generally adopted, has been suggested by Mr. G. Day, of Neath, who states that for mines steam is objectionable in any way, as it condenses and also makes the places where it is employed unbearably hot; and compressed air though useful in many ways yet nevertheless involves expensive compressing machinery, and is a more or less constant source of trouble in the mine on account of its producing such cold in the cylinders of the engines it drives that ordinary lubricants are little or no use, and glycerine has generally to be used; the moisture also is sometime turned into ice. In general form the apparatus is somewhat like a steam injector, but the motive power is water, not steam; and while the vacuum in the steam injector is formed partly by condensation in his it is formed entirely by the velocity of the small stream of water. The elevator consists mainly in a body provided internally with two nozzles, one the discharging nozzle, a fixture, and the other through which the head water flows, either adjustable by means of a hand-wheel and screw or their equivalent, or a fixture like the first, according to the requirements of the case. One form is thus constructed—about the center (lengthwise) of the body is a branch, through which the head or pressure water flows into one enlarged portion or chamber in the body, through which chamber in the direction of the length of the body passes the adjustable nozzle, being hollow, and pierced with suitable holes or openings for the free passage of the water within the chamber to enter. A little further along the body is another branch and chamber forming the intake for the water which is to be removed or raised, and the adjustable nozzle fits sufficiently tight into the intervening space to stop the passage of water between it and the body, though still free to move as needed; packing can be used for this purpose if found desirable. The second chamber terminates in the discharge nozzle which is arranged in any convenient manner, but preferably in a line with the central axis of the body. The action of this elevator is that when the head waters enters the first branch and chamber, it passes through the space into the inside of the adjustable nozzle, and passes out by its orifice (which is preferably contracted) into the discharge nozzle with great velocity, thereby producing a vacuum into which the water to be removed rushes, and is driven out through the discharge nozzle with the head water. The relative areas of the nozzles may be varied to suit circumstances.

A simple form of elevator consists of a short body provided with the two branches, chambers and discharge nozzle as before, but instead of being adjustable by hand-wheel or otherwise, the internal or supply nozzle is fixed (preferably screwed) into the body at or near the bottom of the first chamber projecting into the second chamber, as in the case of the movable one, a suitable cap closing the top of the first chamber. The action is the same as in the former case. A third form has the discharge nozzle, second branch, and chamber, and also the fixed supply nozzle as before, but instead of the first branch being upon the side of the body as in the previous cases, it is attached to the top of the body either beyond the chamber or in place of it, and the head water enters the supply nozzle direct, the supply branch being straight or curved in any convenient direction. In all cases he prefers to taper the discharge nozzle, the smaller area being at the second chamber and the large area beyond it at the end of the body. These elevators can be made of various materials and in various ways; he prefers to cast them in iron or brass, and to screw the different parts together; in working they may be placed vertically, or in fact in almost any position.—*London Mining Journal.*

**SOUTH MOUNTAIN.**—We learn that arrangements are being made to resume operations at South Mountain. A Salt Lake gentleman, named E. Carruthers, who has had much experience with smelting ores, arrived here yesterday, on his way to the South Mountain mines, with the intention of starting work. We believe a Boston company has purchased the property, but of this we are not certain. South Mountain produced considerable base bullion some years ago, and every freight train returning from Idaho was loaded with bars of the metal. For some reason operations were suspended and never resumed. It was at one time thought that South Mountain would rival Eureka in the richness and extent of its mines.—*Silver State.*

**A CHANCE FOR INVENTORS.**—A Lake Superior exchange says: "The copper miners of Lake Superior are greatly interested in securing a perfect machine for the reduction of a certain coarse sand made in their stamp mills. The opening in this direction for mechanical skill and ingenuity is a good one."

# Note on the Estimation of Copper in Speise.

Read before the American Institute of Mining Engineers, by F. C. BLAKE, Mansfield Valley, Pa.

The best method for the estimation of copper in ore and secondary products is that proposed by Dr. Steinbeck for the award offered by the Mansfeldscher Ober-Berg- und Hutten-Direktion. It is based upon the decolorization of the blue ammonia solution of copper by potassium cyanide. It is necessary for this accurate estimation of copper in arsenides that the arsenic be separated from the copper before the ammonia solution is made. The presence of a notable amount of arsenic renders the titration by potassium cyanide inaccurate, the end reaction being obscured by the appearance of a yellowish-green tint towards the end of the titration. The change of the color of this ammonia solution from blue to the tint caused by the presence of arsenic cannot be used for an end reaction for the intensity and quick appearance of the latter color depend upon the amount of arsenic present in the solution.

In the analysis of speise, the method of separating the copper by an oxidizing and reducing treatment in the mufla, to volatilize the arsenic, gives poor results, and there may easily be some loss of this weighed sample. This separation of the precipitated sulphides of arsenic and copper by treating with acetic sulphide, gives good results, but this process is tedious.

I have used the two following methods, which are simpler and more expeditious than those mentioned, with good results.

A. The weighed sample of speise is heated first with sulphuric acid (concentrated acid diluted with about an equal portion of water), which will not usually effect complete solution; sufficient concentrated nitric acid is then added to produce complete decomposition of the speise. This solution is then evaporated for half an hour or a little longer after fumes of sulphuric acid appear, then diluted with water and the copper precipitated by metallic zinc for re-solution; or, if comparative results only are needed, the acid solution is treated directly with ammoniac hydrate. The amount of arsenic present in the final ammonia solution will not be sufficient to interfere with the titration by potassium cyanide.

B. The weighed sample is fused in a porcelain crucible with potassic or sodic bisulphate until completely decomposed. The fused mass is then dissolved in hot water. The solution will contain too little arsenic to affect the end reaction in the ammonia solution.

This method is simpler than the use of sulphuric and nitric acids for solution, but careful watching is required during the process of fusion to avoid loss.

I give the following results of analyses of speise:

	I.	II.	III.
Separation by sodic sulphide.	17.2	12.3	7.95 percent Cu.
" " method A.	17.0	12.1	7.89 " " "
" " " B.	16.9	12.2	" " " "

From another sample of speise I obtained results as follows: Method A, evaporation continued 45 minutes after the appearance of sulphuric acid fumes—5.7% Cu. Method A, evaporation continued but a few minutes after sulphuric acid fumes were first given off—5.1% Cu. By evaporation with hydrochloric instead of sulphuric acid, 5.2% Cu. was obtained. In the last two examples the arsenic was not completely removed and titration was made as closely as possible to the appearance of the characteristic color due to arsenic.

## Prospecting Companies.

A correspondent of the Salt Lake Tribune says: Let me suggest a scheme to some of the enterprising merchants of Salt Lake, who are, more than any other class of citizens, interested in the development of the mines of Utah. Let them form prospecting companies for the purpose of developing prospects. Let there be, say 200,000 shares, half of which may be kept as a working capital, the remainder to be subscribed for by the stockholders in such lots as each may be willing to pay his assessment on. Then purchase a number of prospects and develop them. The result will be that one or two of the number will prove valuable, and assessments would cease, as the working stock would command a sale. There is scarcely the possibility of a failure, if the matter is properly managed, and work prosecuted with vigor. The reason that there is not 20 splendidly paying mines here is because prospectors need help to develop their claims. The mines are here, and will sooner or later be found. Such an organization would benefit the Territory vastly, by the developments it would make. If we wish our mines developed let the men who will derive benefit therefrom aid in the work. There is no reason why there should not be half a dozen such companies. Only be careful to have them composed of men who have means, and who will not want to sell out the moment there is an assessment. The prospector must daily assess himself and take his chances; and when he does find a good claim he is often too poor to open it up, and must sell it for little or nothing, while every other person in the Territory shares in the result.

GOLD-BEARING quartz has been discovered near Fond du Lac, Wis., and a company of Boston capitalists will work the ledge.

## USEFUL INFORMATION.

### Velocities of Wood-Cutting Tools, &c.

Circular-saw teeth, 6,000 to 9,000 ft. per minute; band-saw teeth, hand feed, 3,000 ft. per minute; band-saw teeth, power feed, 4,000 ft. per minute; gang saws, 20-inch stroke, 120 strokes per minute; scroll or jig saws, 800 to 1,500 strokes per minute; planing and moulding cutters, 5,000 ft. per minute; shaping and carving cutters, 6,000 revolutions per minute; Daniel's planer cutters, 8,000 ft. per minute; machine augurs, 1½-inch diameter, 900 revolutions; 2-inch diameter, 1,200 revolutions; 4-inch diameter, 1,800 revolutions; rod end dowel machines, 1-inch and under, 3,000 revolutions; 2-inches and over, 2,000 revolutions; mortising machines, heavy work, 350 strokes per minute; mortising machines, light work, 700 strokes per minute; tenoning cutters, 2,500 revolutions per minute; emery wheels, 6-inch diameter, 3,200 revolutions; 12-inch diameter, 1,600; other sizes in proportion; main shaft for wood-shops, 350 revolutions per minute.

It is quite a common error to give too great a speed to saw teeth. They should not scrape, but cut out the kerf, and all should work evenly. With a moderate speed, the cutting edges and throats being in good order, the greatest useful effect will be obtained from a given amount of power, and the teeth will be most readily kept in order.

COMPRESSED MOTHER-OF-PEARL.—M. Davochel has invented a compressed kind of nautilus shell, solidified with gelatine. Thus prepared it will serve for inlaying or mounting in cabinet work, cartonnage, tablettes, and other industries, and the manufacture of fans, buttons, etc. This product can be figured, stamped, molded by pressure, poured out in the liquid state, and, in fact, takes every kind of form desired. It can be dyed in any color, polished and varnished by the processes used for tortoise-shell, mother-of-pearl, and other analogous substances. To render the shells thin and friable, they are submitted to a strong heat, which separates them into thin scales; these are then pressed in the cylinders of a flattening roller, and afterwards pounded in a mortar. It is then sifted to get rid of the dust, and the powder is treated with gelatine, and shaped into any form required.

WOOL EXTRACTING.—For separating wool from cotton from mixed goods (wool extracting), M. Paul Poulin, of Paris, has patented the employment of the two following solutions in which the goods are immersed: First, chloride of calcium at 20° Ba., 4 volumes; water, 3 volumes. The chloride of calcium at 20° Ba. is itself prepared by dissolving in a mixture of 1 volume of muriatic acid at 22° Ba., and 2 volumes of water, enough chalk to saturate it; or, second, solution of 1 lb. of salt and 1 lb. muriatic acid in ½ gal. of water. This solution is kept boiling by means of steam for 30 or 40 minutes; then cooled and poured on the goods under pressure. The rags are washed and dried, the residue is pure wool.

SOLDERING FLUID.—A soldering fluid which does not occasion rust is prepared in the following manner: Small pieces of zinc are immersed in muriatic acid, and left in it until the acid is saturated with it, which may be known by the cessation of ebullition of the acid, and also by the zinc added after that stage being left undissolved; add spirits of ammonia, about one-third of the quantity of this acid; thin with a little quantity of rain water. When, at the time of adding this zinc, the muriatic acid is heated to a low degree, the solving of the zinc will be achieved sooner. This fluid does not cause rust on iron or steel, and is excellent for all purposes, even for tinning.

DYEING BLACK.—Four ounces copperas and one ounce logwood extract to each pound of goods; dissolve the copperas in water sufficient to cover the goods; wet them in clean water before putting them in copperas water, to prevent spotting; boil them in the copperas water about 20 minutes; take them out, rinse in clear water first, then wash in soap-suds till it seems soft as before it was put in the copperas water; then put into the logwood dye and let it boil about 20 minutes; take out and let it dry; wash before it dries, or after, as is most convenient; it will neither crack, fade, nor grow rusty.

INSTANTANEOUS SILVERING MIXTURE.—To coat copper or brass objects with silver without difficulty or loss of time, the following process is given: Mix 3 parts of chloride of silver with 20 parts of powdered cream of tartar and 15 parts of powdered common salt. Moisten a suitable quantity of the mixture with water, and rub it with a piece of blotting paper upon the metallic object, which must be thoroughly clean. The latter is afterward rubbed with a piece of cotton upon which precipitated chalk is dusted, then washed with water, and polished with a dry cloth.

REMOVING STAINS FROM MARBLE.—To remove stains from statuary marble, take equal parts of fresh oil of vitrol and lemon juice; shake up these substances very thoroughly in a bottle; wet the spots with the mixture, and in a few minutes afterward rub with a soft linen cloth, and the spots will be found to have entirely disappeared.

CAUSES OF EXPLOSION.—At a recent meeting of the Polytechnic Club of the American Institute, Mr. Allen questioned whether the laboratory experiments frequently mentioned to account for boiler explosions were fair equivalents to the conditions of actual practice. From the very nature of the settings, there can be no electrical reason for explosions. It is interesting to note that some years since Mr. Barnett Le Van made some experiments at Philadelphia, which would settle the question in regard to the effects of low water. A boiler was blown off under heavy pressure and the plates made red-hot, water was then sprayed into this boiler upon the plates; the pressure fell instantly and the boiler leaked. This should end the hot-plate and low water theories, especially as we find, in most instances, bad enough workmanship to account for all the explosions which happen.

TO RESTORE BLACK MERINO.—Soak the goods in strong soft-soap suds two hours, then, having dissolved one ounce of extract logwood (which is the amount required for one dress) in a bowl of warm water, add sufficient warm—not hot—water to cover the goods, which are to be taken from the suds without wringing. Allow the goods to stand in the logwood water over night; in the morning rinse in several waters without wringing; in the last water add one pint of sweet milk, which stiffens the goods a little; iron while quite damp. It will not crack, and looks like new.

ARTIFICIAL INDIGO.—One of the most interesting and promising industrial discoveries made during the past year was that of Prof. Bayer of an artificial coloring substance as a substitute for vegetable indigo. This new product is gradually coming into use in England, and, according to the *Textile Manufacturer*, bids fair to soon become a formidable rival to the vegetable product.

VARNISH ON METAL SURFACES.—To make alcoholic lacquers or varnishes adhere more completely to polished metal surfaces, one part boric acid should be added to 200 parts of varnish. This composition will adhere so firmly and become so completely glazed as to be removed only with difficulty. Be careful not to add too much of this boric acid, as it injures the gloss in that case.

## GOOD HEALTH.

### The Organ of Voice.

The larynx is the organ of voice, and is placed at the upper part of the air passage. It is situated between the trachea below and the base of the tongue above, and forms that visible projection in the middle part of the neck known as *Adam's apple*. Its form is that of a triangular box—narrow below and broad above. It is composed of nine different cartilages, bound together by ligaments and moved by numerous muscles. Below the larynx stretches the windpipe, passing down into the lungs and subdividing like the branches of a tree into the right and left bronchi.

The laryngoscope enables us to look down into the larynx and watch its many movements. The image we see in the mirror differs materially from anything else we meet with in our anatomical studies. The epiglottis occupies the highest part of the laryngeal image. Its free border may be watched, alternately rising and falling during the examination. It presents a scroll-like form, and in the middle we see the under surface turned up like a lip. The vocal cords are the next most prominent objects in the image. They stretch from the front to the back of the larynx and are to be seen as two smooth, white bands, standing out in remarkable contrast to the surrounding red structures, alternately approaching and receding from each other as the patient breathes. These two moving hands once seen will never be forgotten. Right here permit the remark that Laryngology has done many wonderful things in detecting and remedying the defects and diseases of the human voice. Light has been thrown into dark places; slight changes have been readily diagnosed; tumors, ulcerations and abrasions are seen at a glance, and thus every appliance of science is brought to the aid of the most beautiful and fascinating specialty in the whole domain of medicine and surgery. As the statue of Memnon is said to have grown vocal when touched by the first beams of the morning sun, even so has the voice of the dumb broken forth into songs of thanksgiving when set free by this skillful hand of our God-given art!

As the skin covers the body on the outside, so the mucous membrane lines it in the inside, and under certain circumstances they become readily transformed into each other. "This is only a single instance of the marvelous handiwork of Nature, and one may well stand in awe and in wonder when he contemplates the Divine wisdom which has fashioned such an exquisitely fitting garment, woven without seam, adapted by a hundred variations to every office it has to fulfill, covering the body outside and lining it inside, winding at every turn through the intricate labyrinth and inclosing within its folds this strange machinery of life." We not only trace the finger of God upon this stone tables of the earth, the letters and the law of its everlasting form, but we see it in every line and movement of this wonderful human frame of ours!—*Sanitary News*.

## Tobacco Smoke.

In further research on this subject Dr. Le Bon finds that collidine, the new alkaloid existing in tobacco smoke, with other aromatic principles, and prussic acid, as well as nicotine, is a liquid of agreeable and very penetrating odor, and as poisonous as nicotine, the twentieth part of one drop sufficient to paralyze and kill a frog. It is this prussic acid and various aromatic principles that cause headache, giddiness and nausea in smoking certain tobaccos that contain little nicotine. Other tobaccos, rich in nicotine, have no such effects. This tobacco contains most prussic acid and collidine are those of Havana and the Levant. The dark semi-liquid matter which condenses in pipes and cigar-holders contains all the substances just named, as well as carbonate of ammonia, tarry and coloring matters, etc. It is very poisonous. Two or three drops of it will kill a small animal. The combustion of tobacco destroys but a small part of the nicotine, and most of this appears in the smoke. The proportion absorbed by smokers varies according to circumstances, but hardly ever falls below 50 centigrammes per 100 grammes of tobacco burnt. About the same quantity of ammonia is absorbed at the same time. Naturally, more of the poisonous principles are absorbed where the smoke is breathed (as in a room); less in the open air. A frog placed in a receiver containing a solution of nicotine, with about one drop of that substance to a little of water, succumbs in a few hours. Tobacco smoke contains about eight milliliters of carbonic oxide per 100 grammes of tobacco burnt. This poisonous properties of tobacco smoke are not due to this gas, as has been maintained in Germany.

THE WILLOW AS A PREVENTIVE OF MALARIA.—Mr. Von Linnep, the Swedish Consul, writes from "Mahazik, near Smyrna," to the *London Times*, as follows: "Before the uncalypnus was ever heard of in Asia Minor, I had seen the bark of the willow used as a febrifuge. I had remarked the easy and inexpensive reproduction of this tree, its quick growth in damp places, its excellent qualities for fuel and for agricultural implements, and its great advantages for strengthening the banks of capricious streams, and had thence taken every opportunity after the winter floods to stick willow cuttings along the banks of streams and in other damp places in my property; also to scatter plane-tree seeds in marshy spots. The result has been that, whereas 20 years ago the full-grown trees in this neighborhood might have been counted, a luxurious growth of willows and plane-trees marks my place, fuel is abundant, fever is steadily decreasing, the malarious propensities of the streams are checked, my neighbors have to come to me for agricultural implements, and I have not had to go for timber for rough purposes." It may be interesting to observe in this connection that the comparatively new but well-known antiseptic preparation known as salicine is derived from the bark of a certain species of this willow. It is of a pure, bitter taste and highly febrifuge in quality. It is largely used in various solutions, in surgical operations, and is the most effectual preventive of putrefaction in the system known.

CURE FOR COLD-FEET SLEEPLESSNESS.—The *British Medical Journal* says this is the plan to adopt with cold feet: They should be dipped in cold water for a brief period; often just immerse them, and no more, is sufficient; and then they should be rubbed with a pair of flesh-gloves, or a rough Turkish towel, till they glow, immediately before getting into bed. After this a hot-water bottle will be successful enough in maintaining the temperature of the feet, though without this preliminary it is impotent to do so. Disagreeable as the plan at first sight may appear, it is efficient; and those who have once fairly tried it continue it, and find that they have put an end to their bad nights and cold feet. Pills, potions, lozenges, "night-caps," all narcotics, fail to enable the sufferer to sleep successfully. Get rid of cold feet, and then sleep will come of itself.

KEROSENE AND SALT FOR DIPHTHERIA.—A correspondent of the *New York Sun* says: In 1862, on a plantation in South Alabama, where there was great difficulty in securing good medical advice, I saw a whole plantation of blacks, as well as the white members of a large family, successfully treated for diphtheria with kerosene and salt, used thus: Every patient was given a lump of rock salt about the size of a boy's marble, and instructed to keep it in his or her mouth, swallowing the salty saliva. At the same time the throat was rubbed with kerosene oil, and a flannel saturated with kerosene kept around the neck until the symptoms were abated or entirely gone. If necessary, mild cathartics were given. Not a case was lost, and there were fully 150 in all on the plantation.

TREATMENT OF FETID PERSPIRATION OF THE FEET.—A correspondent of the *New York Medical Record* writes: "As a recipe for fetid perspiration of the feet seems to be in order, and as I do not remember seeing mentioned one that never failed in my hands, I herewith send it: A 1% watery solution of permanganate of potassa. Bathe the feet at night and morning, oftener if necessary, even to every hour, letting the feet dry after each bath without wiping. A stronger solution may at times be necessary; generally a weaker one will answer. The stronger the solution the greater the discoloration of the feet, but, as it is temporary, patients prefer it to the fetid moisture."

## Passing Events.

We still continue to hear of rich strikes in California mines. The Rainbow quartz mine, in Sierra county, is proving itself fabulously rich. In fact the ledge is one of the richest ever discovered in this State. The *Mountain Messenger* says that last week three men in one day panned out 29 pounds of gold. For many days the yield has been about the same, and there seems yet to be no signs of its giving out. The Rawhide mine, as we stated recently, took out \$75,000 in about 10 days, the mine having been abandoned for some 10 years before the last work was commenced.

Very conflicting reports come from Wood River. Some people are very sanguine; others, again, are despondent. We give in other columns some detailed information about this region.

Arizona still attracts many immigrants, though it is for the moment overshadowed by Idaho. The country is a very rich one, and now that it has a railroad, is making rapid strides in advancement.

The spring now being fairly opened, prospecting has begun in the mountains, and from now on we may expect to hear of numerous strikes by individuals in the army of prospectors now exploring our mineral regions.

The principal item of interest during the past week has been the receipt of a sample of Clipper Gap iron in this city to test. The iron is made with charcoal and presents a very good appearance. Its qualities will soon be determined, the Union Iron Works proprietors being prepared to give it a thorough test. We shall be very glad to hear it turns out well, as we will then be sure of having a good supply of iron within our borders. We shall give the details of the tests when they are completed.

## Lumber and Wages.

About all the lumber mills on the coast streams from this port up to Mendocino City have had to raise the wages of laborers, on account of the scarcity of men. Two years ago they paid from \$30 to \$40. Last year they paid \$35 to \$45. This year they pay \$40 to \$50. These men are also boarded. This rate of wages is for hands in the woods, choppers, "jackscrews," chain tenders, sawyers and swamps. The common roustabouts, such as the swamps and sawyers, get the \$40, and the choppers, "jackscrews" and chain tenders, \$45 and \$50. The common mill hands have also been raised to \$35 and board.

Of course the more skilled get larger wages. Foremen in mills get about \$100, according to their experience, etc. Engineers get \$75; the head sawyer about \$70; or teamsters about \$70. They formerly paid 2½ cts. apiece for sawing ties, 2½ cts. for hewing them, 2½ cts. for splitting, and 2½ cts. for swamping and felling, making about 10 cts. Now they pay 6½ cts. for the sawing and splitting, and 3½ cts. for the hewing. Then there is the swamping and felling. At Caspar they now offer 25 cts. apiece for ties at the landing. Last year they could only get 22 and 23 cts.

The reason of the increase of wages is the scarcity of men. There is a class of men who stay on the coast right along and who do the kind of work referred to. During the past two or three years, while times have been dull, the lumber trade has been dull and many of the mills have either shut down or run on short time. Many of the men have sought other employment or gone away, and the desirable labor is therefore scarce now that the lumber business is reviving and the mills are starting up. The demand for lumber is now increasing and the mills are starting up again.

Beginning at Rockport, south of Mendocino, the mill is running and cutting about 30,000 ft. a day. The Ten Mile River mill is also running and cutting about 30,000 ft. a day. The Noyo mill, we believe, is not running. The Caspar mill, which can cut about 60,000 ft., is cutting about 40,000 ft. a day. The Mendocino mill at Big River, which has a capacity of 60,000 ft. a day, is cutting about 40,000 ft. At Little River, the mill is, we believe, closed down. The Alhion is sawing about 30,000 ft. a day. There are two mills at Salmon creek, one of them now being built by L. E. White. The other is sawing about 30,000 ft. a day. At Navarro river they are doing about the same. The mill at Greenwood creek, Cuffey's Cove, run by A. D. Moore, is sawing between 30,000 and 35,000 ft. a day. The Gualala mill is cutting from 40,000 to 50,000 ft. now. The Duncan mill, which ships by railroad, is, we understand, cutting about 35,000 ft.

The six mills at Humboldt bay, one at Trinidad and two at Crescent City, are not understood affected by the advance in wages. The demand for lumber is now greater than for some three years. The available acreage of Humboldt county redwood lands is figured at 510,000 acres. There are hundreds of thousands of acres of timber lands along the coast yet, which are untouched. Now that business is picking up again, a revival of the lumbering interests of the coast has occurred.

## Gathering Mining Statistics.

Mr. A. W. Lawver, Statistician of the Mint Bureau of the Treasury Department, connected with the branch Mint of this city, has started on a tour to visit certain California mines, so as to make arrangements to more fully obtain information as to the production, and gather such other material as will aid the Director of the Mint in making his report for the fiscal year. Mr. Lawver will go first to Smartsville, then to North Bloomfield, Nevada City, Dutch Flat, Colfax, Auburn, Georgetown, Placerville, El Dorado, Plymouth, Amador City, Sutter Creek, Mokelumne Hill, Murphy, Angels, San Andreas, Sheep Ranch, Sonora, and intermediate points. Other trips will probably be made in other directions.

This work is a very good one, and is really necessary if we are to keep ourselves posted as to the yield of our mines. The gathering and publication of the statistics helps the miners, inasmuch as the result of their work is made known to the world. It must be understood, however, that the yield of the mines is only published in the aggregate, by counties, etc., but in no case is the yield of any one mine made public. Miners, therefore, need not fear to give the yield of their mine to Mr. Lawver, as such matters are not published, but are only used to make up aggregates. The local papers can assist Mr. Lawver by making this point apparent to the miners of their neighborhood.

Mr. Lawver is doing very valuable and intelligent work in his department. He has exercised great care in collecting his statistics, and has been very industrious in getting at proper sources of information. The material gathered will appear in the report of the Director of the Mint, and the statistics, being carefully gathered, will be reliable and correct.

THE Little Chief mining company of Leadville is reported to have \$100,000 in the treasury, and stockholders are expecting a dividend soon.

## Minerals Containing Silver.

Only a small proportion of the large amount of silver which is at the present time produced for commercial purposes is found native, and then not pure, as it is generally alloyed with a little copper, gold, platinum, mercury, arsenic, iron, lead, bismuth or antimony.

Native silver occurs in masses or in arborescent and filiform shapes in veins traversing gneiss, schists, porphyry, and other rocks; it also occurs disseminated in native copper and galena, but usually invisible to the naked eye, therefore requiring the aid of a good microscope to determine its presence.

Silver when pure has a metallic luster. Color and streak, silver white. Ductile. Hardness, 2.5—3. Specific gravity when pure, 10.5. Minerals containing silver are found in veins of nearly all descriptions, and even in sea water minute traces have been found by a careful analysis.

Silver is a metal extensively used in the arts and manufactures, and many products contain more or less proportions.

Silver will be found in the products as well as in the refuse from nearly all lead and copper smelting works, if carefully looked for, and a very small amount can be determined with accuracy. Any mineral or alloy containing what is called a "trace" of silver about one-half ounce to the ton of 2,000 lbs., can be assayed, and the metal extracted and determined with accuracy.

Mr. George Attwood, in his "Practical Blow-pipe Assaying," gives the following list of principal minerals containing silver:

Argentite, silver glance containing 87% silver, with sulphur.

Stephanite, brittle silver ore, containing 63% silver, with sulphur and antimony.

Pronstite, light red silver ore, containing 65.4% silver, with sulphur and arsenic.

Pyrrargyrite, dark red silver ore, containing 59% silver, with sulphur and antimony.

Argentiferous grey copper ore (fahlerz), containing from 5.7% to 18-31.8% silver, with antimony and sulphur.

Argentiferous sulphide of copper, containing 53% silver, with sulphur and copper.

Polybasite, containing 72-94% silver, with copper, sulphur, arsenic and antimony.

Chilenite, containing 86.2%, with bismuth 13.8%.

Bromyrite, containing 57.4% silver, with bromine 42.6%.

Cerargyrite (horn of chloride), containing 75.3%.

Embolite, containing 60—72% silver, with bromine and chlorine.

Sternbergite, containing 33.2% silver, with iron 36%, and sulphur 30%.

Iodyrite, containing 46% silver, with iodine 54%.

Selenic silver, containing 11.6-42.8-65.5% silver, with selenium, copper and lead.

Hessite, containing 62.8% silver, with tellurium 37.2%.

## Geographical Society of the Pacific.

This society is a recent organization, the objects of which are to encourage geographical exploration and discovery; to investigate and disseminate geographical information by discussion, lectures and publications; to establish in this, the chief maritime city of the Western States, for the benefit of commerce, navigation and the industrial and material interests of the Pacific slope, a place where the means will be afforded of obtaining accurate information, not only of the countries bordering on the Pacific ocean, but of every part of the habitable globe; to accumulate a library of the best books on geography, history and statistics; to make a collection of the most recent maps and charts—especially those which relate to the Pacific coast, the islands of the Pacific and the Pacific ocean—and to enter into correspondence with scientific and learned societies whose objects include or sympathize with geography.

The society will publish a bulletin and an annual journal, which will interchange with geographical and other societies. Monthly meetings are to be held, at which original papers will be read or lectures be given; and to which, as well as to the entertainments to distinguished travelers, to the conversations, and to the informal evenings, the fellows of the society will have the privilege of introducing their friends. The initiation fee to the society is \$10; monthly dues \$1; life fellowship, \$100.

At a meeting held at the Palace hotel on the 12th inst., the following gentlemen were elected for the ensuing year: President, Geo. Davidson; Vice-Presidents, Hon. Ogden Hoffman, Wm. Lane Booker, H. B. M. Consul, and John R. Jarboe; Foreign Corresponding Sec., Francis Berton; Home Cor. Sec., James P. Cox; Treas., Gen. C. I. Hutchinson; Sec'y, C. Mitchell Grant, F. R. G. S. The council is composed of the following: Hon. Joseph W. Winans, Hon. J. F. Sullivan, Ralph C. Harrison, A. S. Hallidie, Thos. E. Stevin, F. A. G. S., W. W. Crane, Jr., W. J. Shaw, C. P. Murphy, Thos. Price, Edward L. G. Steele, Gerrit L. Lansing, Joseph D. Redding. The Trustees are Geo. Davidson, Wm. Lane Booker, Hon. Jno. S. Hager, Geo. Chismore, M. D., Selim Franklin.

## The Behring's Straits Currents.

It will be remembered that a short time since, we mentioned the fact that W. H. Dall, of the U. S. Coast Survey, who has passed a number of years in Alaskan waters, on Coast Survey duty, denied the existence of any branch of the Kuro-Shiwo, or Japanese warm stream, in Behring's straits. That is, he failed to find evidence of the existence of any such current, although he had made careful observations. At the islands in Behring's straits, his vessel had tailed in opposite directions with ebb and flood tide, and he thought the only currents there were tidal in their nature. The existence or non-existence of this current is an important point in Arctic research on this side of the continent.

At the last meeting of the Academy of Sciences, Prof. Davidson, of the U. S. Coast Survey, author of the "Alaska Coast Pilot," refuted Dr. Dall's opinion of the non-existence of a branch of the Kuro-Shiwo, or Japanese warm stream, from the north Pacific into the Arctic ocean, through Behring's strait. He said that in 1857 he gave to the Academy his own observations, and recently he had conferred with Capt. C. L. Hooper, who commanded the U. S. steamer, *Thomas Corwin*, employed as a revenue steam-cruiser in the Arctic and around the coast of Alaska. Capt. Hooper confirms the opinions of all previous navigators, every one of which, except Dr. Dall, say that a branch of this warm stream passed northward into the Arctic through Behring's strait. It is partly deflected by St. Lawrence island, and closely follows the coast on the Alaskan side, while a cold current comes out south, past East cape in Siberia, skirting the Asiatic shore past Kamshatka, and thence continues down the coast of China. He said ice often extended several miles seaward, from East cape on the Asiatic side of Behring's strait, making what seamen call a false cape, and indicating cold water, while no such formation makes off on the American side, where the water is 12 degrees warmer than on the Asiatic shore off the Diomed islands, situated in the middle of Behring's strait, the current varies in intensity according to the wind.

Frequently it is almost nothing for several days, when after a series of southerly winds the shallow Arctic basin has been filled, under a heavy pressure, with an unusual volume of water, and a sudden change to northerly winds, makes even a small current setting southward for a few days, just as at times the surface currents set out our Golden Gate continuously for 24 and 48 hours, as shown by the United States coast survey tide ganges. Whalers report that the incoming water then flows in, under the temporary out-flowing stream.

Old trees, of a variety known to grow in tropical Japan, are floated into the Arctic basin as far as past Point Barrow, on the American side, but none are found on the Asiatic side, or near Wrangel Land, where a cold stream exists, and ice remains late in the season. On the northern side of the Aleutian islands are found coconut husks and other tropical productions stranded along the beaches. The American coast of Alaska has a much warmer climate than the Asiatic coast of Siberia, and the American timber-line extends very far north. The ice opens early in the season on the American side, and invariably late on the Asiatic.

Capt. C. L. Hooper says that when just north of Behring Strait, off the American coast, in the Arctic basin, the U. S. steamer *Thomas Corwin*, when hauled for 24 hours, drifted 40 miles to the northward. From all these, and other facts, and the unanimous testimony of American whalers, who have for years spent many months annually in the Arctic, and from his own observations, he argued that a branch of the Kuro-Shiwo, or Japanese warm stream, unquestionably runs northward through Behring's strait into the Arctic basin along the northwestern coast of Alaska.

Prof. Davidson then called to mind the testimony in regard to the existence of Plover island, between Herald island and Wrangel land, which he said was first made public through this academy. The evidence of Capt. Williams, Thomas and Long, were recited and highly praised. One of the officers of Admiral Rodgers' expedition climbed to near the top of Herald island, at a time of great refraction, when probably a false horizon existed, and hence did not see Plover island, although Wrangel land was in sight.

Prof. Davidson thinks all the authorities are against Dr. Dall, who attributes the warm current he observed on the American coast, to water from the Yukon river; and to the large expanse of shallow water exposed to the sun's rays. As Dall's observations only covered a few days of possibly exceptional weather, and the whalers, and Captain Hooper's cover vastly longer periods, and whalers all say it is a pretty hard thing to heat southward through Behring's strait, owing to the northerly current setting into the Arctic, we are forced to the conclusion that Dr. Dall has mistaken the exception for the rule, and his conclusions are therefore erroneous. When, in 1824, Wrangel went north, he, like others, always found broken ice and considerable open water. In 1867, when Capt. Thomas Long made his memorable survey of the coast of Wrangel land, the season was an exceptionally open one, and in California we had heavy rains, extending into July.

## Check Assays.

George Attwood, son of Melville Attwood, Esq., of this city, and at one time Superintendent of the famous Emms mine, has recently published a manual of "Practical Blowpipe Assaying," with 74 woodcuts. The work is an effort on the part of the author to record the methods of assaying adapted by himself during 18 years of foreign travel, in hopes that they will assist others who have to make examinations where complete assay offices and laboratories are not to be found. The general system of assaying adopted is a simple and direct one. Sixty-four elements are mentioned in the work, and the assayer may be asked to determine the presence of any one of these. The system being a direct one, directions are laid down for the separate determination of each. For assaying, the author has adopted the system of checking his assays by synthetic assays, or, in other words, preparing an assay with a weighed quantity of the chemically pure metal or element to be determined, and mixing it with materials resembling as nearly as possible those of the ore, alloy or compound to be assayed, and then, after the completion of the assay, adding to the direct assay the loss found to have been incurred in the synthetic.

In the assay of gold and silver alloy a check assay is necessary. In silver assays Mr. Attwood thinks it is absolutely necessary, and by using the same most accurate results may be obtained in silver and gold coins; bars and in-

## Safety on Railways.

There is a certain ratio between the number of passengers carried and the number of accidents to life and limb, on every railroad. But it is found by experience that the danger in traveling does not increase with the number of passengers or frequency of trains, so much as on the amount of freight. The relative safety of most of the chief English lines is well known. For instance, the Lancashire and Yorkshire company pay as compensation for damages £1,200 for every million passengers carried. Others a decreasing amount, until the Metropolitan is reached, and this pays only about £6 for every million passengers carried; yet on the latter the trains are more frequent and greater in number.

This English experience points to a reform there as here. That goods traffic and passenger traffic should be kept separate and distinct; and that freight traffic should be as far as possible carried on at night, when the mail trains are fairly out of the way. This is the conclusion of the *Engineering Times*, which has paid considerable attention to the question.

Each year, however, we find that our railway business increases, yet the number of deaths by accident does not seem to increase in proportion, showing that the increase is not in a constant ratio. It is astonishing how few accidents there are on our crowded roads, where it is considered that the safeguards are so much fewer than in Europe. The cross-

## The Mechanics' Fair.

A meeting of the Sixteenth Industrial Exhibition of the Mechanics' Institute was held on Wednesday evening. Mr. J. H. Culver, the Secretary, who has just returned from a trip East, was present.

Over one hundred applications for space were read and referred to Superintendent Gilmore. Bids for the privilege of keeping a restaurant, ice-cream stands, candy-stands, and publishing a daily newspaper were opened and referred to the proper committee.

The President stated that a number of leading citizens of Oregon had signified their intention of making an exhibit of the products and resources of that State similar to the one made at the Centennial Exposition at Philadelphia in 1876.

Reports were read from different committees. One was to the effect that it was proposed to add a new feature to this fair in the shape of an exhibition of minerals, and the collection would be the finest and most complete ever seen on this coast. Another committee reported that the viticultural and horticultural display would surpass those of any previous year, and it was probable that both departments would be under the management of the respective State Commissions. It is also contemplated to make an entirely radical change in the appearance of the interior of the Pavilion, and the arrangement of the exhibits.

The opening exercises will take place on Tues-

## Blowpipe Fuel.

In using the blowpipe, pure olive oil is the best fuel for reductions and quantitative fusion. Mr. George Attwood, who has had great experience with the blowpipe, says in his "Practical Blowpipe Assaying" that alcohol makes a good fuel for qualitative work, and is especially useful for scorification and cupellation of silver and gold alloys, as well as for heating glass tubes and mattresses, and is employed in the assay of mercury. By adding about one-seventh part of turpentine to alcohol the reducing strength is increased.

Refined rape seed oil answers very well as a blowpipe fuel. The ordinary illuminating gas makes a good fuel, but it is much better for oxidation than for reduction.

The flame of a wax candle, or even the flame of an ordinary candle, answer the purpose when nothing better can be found. Although assays can be made from the flame supplied by candles, yet such assays are generally attended with considerable difficulty, owing to the small volume of the flame.

Paraffine melted and passed into a lamp having an open top and a broad wick attached to one end, answers nearly all the purposes required for blowpipe fuel. The great objection is that soot accumulates on the glass tubes or porcelain vessels when heated over the flame.

In some countries—the interior of South America, for instance—alcohol cannot be procured, except at a great cost; but as crude spirits, made from sugar-cane, etc., are generally

SILVER BAY, BARANOFF ISLAND, ALASKA TERRITORY.

gets can be valued or stamped for market, and found to be correctly assayed by following the method described. The first part of the book treats of the mouth blow-pipe and apparatus; the second part of qualitative determination; the third part of assays of the commoner metals; the fourth part consists of conveniently arranged tables. Mr. Attwood has written a very complete and valuable hand-book, the instruction being very clear and plain. The book is useful to either beginners or more advanced students.

## Alaska Mining Regions.

As considerable attention is now being turned to Alaska as a mining region, we give an engraving on this page from a sketch by Major Bell, which shows the general characteristics of the coast line. The engraving is a representation of Silver Bay, Baranoff Island, which is the island on which Sitka is built. It is named in honor of Baranoff, a Siberian merchant of education, who was the real founder of the settlement of New Archangel, or Sitka. The entire island contains a number of gold-bearing quartz veins. Fourteen miles from Sitka, near the head of Silver Bay, are the works and mines of the Alaska G. & S. M. Co. The territory of Alaska covers an immense tract, and it will probably be many years before it is even partly prospected. Last season many mines were found and no doubt many more will be this year, for a number of prospectors have gone up there prepared to explore.

The climate of the country, in the neighborhood of Sitka, is by no means rigorous. There is some considerable snow, but it never gets very cold. The whole coast is more or less foggy and considerable snow falls. The great difficulty about prospecting is the heavy thick timber which comes to the water's edge. For this reason hundreds of miles of the coast have never been examined. It will not be very long, however, before thorough search will be made all along the coast and back into the interior, for gold, silver and coal mines.

WHITE RIVER arastras, Tulare county, are making returns of \$7 or \$8 a piece per day.

ings are not guarded here and the trains do not slow up. The local road doing the largest business in this vicinity is that running through Oakland and Alameda. There are some millions of passengers carried each year, yet very few persons are hurt when the amount of traffic is considered. There is no freight traffic on this part of the road, and, if the English experience applies here, that may be a reason. However, it is a fact that notwithstanding the constantly running trains from 5 A. M. to 12 midnight through the streets of two populous cities the accidents each year number much fewer than one would be disposed to estimate.

## Irrigation and Wells.

There is a noticeable feature of irrigation worthy of study and investigation for the benefit of the near future, now developing in our irrigating districts. On the dry plain lands of Fresno county, in places where wells had to be sunk from 35 to 60 ft., after irrigating a portion for several seasons, it is found that surface water is obtainable in from 5 to 8 ft. The water surface in wells at Sheep Camps, 10 miles or more from irrigation, is found to be several ft. higher than a year or two ago. What does this argue? Does it not foretell that if all the dry land should be once flooded and thoroughly irrigated, say during the seasons of the year when waste waters are over abundant, would not thereafter one half the supply heretofore estimated as necessary for irrigation be ample? We should be glad to have readers of the *RURAL* send us facts bearing on this subject, together with their opinions on the matter.

At the Eisen vineyard formerly it required 65 ft. to reach surface water; now, only 6 ft. On the Central California colony, at Mr. Marks' place, a well 35 ft. deep, as at first required, now has water about six ft. from the top; and seven miles west of this colony, a well six ft. deep now has water rising to within two ft. of the surface. On the Temperance colony, 47 ft. depth was at first required; now the water in some places comes within dipping distance.

One result has been to cause the boring and piping of artesian pumping wells to lower strata for a better and healthier supply of water.

day, August 2d. The orator has not yet been determined upon.

A report from the Secretary of the Institute shows that the net profit derived from the first eight fairs given by the Institute, including the sale of the building in which they were held, was \$88,860.30; and from the last seven fairs, all of which have been held in the building on the corner of Mission and Eighth streets, the net profit paid to the Institute was \$72,674.18, besides paying for the exhibition building and contents, now the property of the Institute, which cost \$106,230.61, thus showing a grand total of \$267,865.09 as the result of the previous fairs held under the auspices of the Institute. The managers state that nothing will be left undone to make this, the last fair to be held in the present pavilion, the most attractive of all the exhibitions yet given, and the public is promised many novelties which will be both pleasing and instructive.

## Guiding Attachment for Headers.

W. H. Keen, of Woodbridge, exhibited at the Lodi meeting his combined lever and tiller or header guider for which he secured a patent last year. He tested the apparatus in his own heading during the harvest of 1880, and cut, himself, 375 acres toward the last of the season, the guider enabling him to do the work with great ease and success. The design of the guider may be briefly described as follows:

This invention contemplates forming a peculiar jack-staff, carrying the caster guide-wheel below, and arranged above as a guide for the cutter-bar level, the whole being in front of the driver, so that a seat may be provided at the rear end of the beam, upon which the driver may sit during his work. The tiller for steering the header is swiveled on the rear end of the cutter-bar level, and so combined with it as to serve also as a means of raising or lowering said level. It further consists in forming in a peculiar manner an automatically movable fulcrum for the cutter-bar lever, to keep the header on an equal balance, so that the cutter-bar is raised with little friction, and the strain relieved from the links connecting the cutter-bar frame with the pole carrying the guide-wheel and driver.

Mr. Keen expects to give his device full test this year and introduce it for the use of the public next season.

plentiful in such places, they afford the explorer a good substitute for alcohol, as well as oil, owing to the presence of more carbon than pure alcohol contains. The spirits, however, contain some water; and after the fuel is about half consumed it is best to empty the lamp and fill again with fresh spirits.

## The Bamboo.

Now that different varieties of the bamboo are growing well in California soil and interest in the plant is general, items of the great usefulness of the plant abroad are valuable. We have had many such before, but testimony from a well-known Californian who has just returned from Asiatic travel is pertinent. Hon. Irving M. Scott, of this city, has been delivering lectures before the Mechanics' Institute on his observations abroad, and in one of these lectures is the following concerning the bamboo: One of the features of Japan is the use they make of bamboo. I do not know of anything that would be more valuable to California, or any climate where it would grow, than this one article of bamboo. If I can recall the uses to which I saw it put I will give them to you. If you see a Japanese ship or a small boat—a schooner or a yacht, as we would call them—you will see that the masts are of bamboo; the yards are of bamboo; the sails are of bamboo; the ropes are of bamboo, and the poles with which she scuds along or comes up to the wharf are of bamboo. The captain's slippers are made of bamboo, and the carpet in the captain's room is made of bamboo. His drinking cup may be of bamboo, and many of the ornaments are large stalks of bamboo, carved. They use it for scaffolding to build their houses. They make their partitions in all their modern houses with a net-work of bamboo, on which they fix their plaster, in place of laths, as we do. They use it for clothing, for pipe stems. They pipe their hot and cold water in bamboo pipes; they make strings, toys and fans of bamboo, and bamboo makes the handsomest grove that we saw in our travels—slender and straight, and its foliage was as feathery as it is possible to conceive. Inside of the castle at Kioto, the finest grove said to exist in the world, we saw.

HOME PRODUCTION.

HOME MANUFACTURE.

## BERKELEY LUBRICATING OIL WORKS, BERKELEY, CALIFORNIA.

Manufacturers of Machinery and Lubricating Oils, White Wool Oils, Leather Oils and Compounds.

**RAILROADS, STEAMSHIPS AND MILLS SUPPLIED AT REDUCED RATES.**

Our oils are produced under a new process, and guaranteed to be Superior to any oils in the Market.

**A. C. DIETZ & CO., Proprietors.**

Office and Salesroom, No. 9 Front Street, near Market, San Francisco.

IMPORTERS AND DEALERS IN

**PAINTS, OILS, WHITE LEAD, VARNISHES  
AND LAMP STOCK.**

## MOREY & SPERRY,

MANUFACTURERS OF

**Gold and Silver Grinding and Amalgamating Machinery**

**HOWLAND'S PULVERIZER** Takes the Place of the Cumber-  
some Stamp Mill and can be put up in one day ready for work.

IT HAS BEEN FULLY PROVED AND TESTED.

It weighs complete, 7,000 pounds. It costs \$1,500 ready for the belt. Will crush one  
hour of hard quartz that will pass through a 40-mesh screen. The wear is less  
in the stamp mill. Its wearing parts are plain castings and can be dropped into  
position in a few moments, as shown by the letters A, B and C. No  
bolts or keys are required; it can be set upon the floor of a mill  
with no expense for foundations, and can be used to crush and  
work in charges or continuous. It will amalgamate either gold or  
silver ores, making a simple, cheap and effective mill. It requires  
twelve-horse power.

Stamp Mills' Rock Breakers, Crushing Rolls, Amalgamating  
Pans and Separators for Gold and Silver Ores, Chlori-  
dizing Furnaces, Retorts, Rock Drills, Air Com-  
pressors, Steel Shoes and Dies for Stamps, and every  
description of Mine and Mill Supply. Iron Work  
complete for Wood Frames, also.

**SPERRY'S  
WROUGHT IRON FRAME  
FOR STAMP MILLS.**

Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to  
put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores.  
Wet or Dry Crushing Mortars.

**MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.**

## LEFFEL'S IMPROVED WATER WHEEL.

**PRICES REDUCED!**

**PATENTS REISSUED 1868.**

The "OLD RELIABLE" with improvements, making it

**THE MOST PERFECT TURBINE NOW IN USE.**

Comprising the **Largest** and the **Smallest** Wheels, under both the **Highest**  
and **Lowest** head used in this country. Our new Illustrated Book sent free to  
those owning water power.

Those improving water power should not fail to write us for **New Prices**,  
before buying elsewhere. New Shops and New Machinery are provided for making  
this Wheel. Address

**JAMES LEFFEL & CO., Springfield, Ohio,**  
and 110 Liberty St., N. Y. City.

**PARKE & LACY, Sole Agents, 21 and 23 Fremont St., S. F.**

## Pacific Rolling Mill Co.,

**SAN FRANCISCO, CAL.**

MANUFACTURERS OF

**RAILROAD AND MERCHANT IRON,**

ROLLED BEAMS, ANGLE, CHANNEL AND T IRON, BRIDGE AND MACHINE BOLTS, LAG SCREWS, NUTS  
WASHERS, ETC., STEAMBOAT SHAFTS, CRANKS, PISTONS, CONNECTING RODS, ETC., ETC.

Car and Locomotive Axles and Frames, and Hammered Iron of Every Description.

**HIGHEST PRICE PAID FOR SCRAP IRON.**

Orders Solicited and Promptly Executed.

Office, No. 202 Market St., UNION BLOCK.

## INGERSOLL ROCK DRILL. PRICES REDUCED.

Parties requiring Drills can get them at agents' rates  
by applying to

**GEO. R. FOARD,**

Sole Agent for Pacific Coast.

No. 18 First St., S. F.

The only Depot where Standard Drills and Duplicate  
Parts can be obtained.

## A Card from Architects.

**The California Architect and  
Building Review.**

Office, No. 240 Montgomery Street, San Francisco, Cal.  
It is with pleasure that we publish the following from  
prominent Architects in this city:

Believing that a journal of its kind is a necessity on this  
coast, and judging from what has appeared in the "Quarter-  
ly Architectural Review," we are led to believe that the  
**CALIFORNIA ARCHITECT AND BUILDING REVIEW**  
will be worthy of generous support and encouragement. We  
therefore pledge our cordial sympathies, personally, and hope  
that the enterprise will receive kindly recognition and liberal  
support from all Architects and Builders and the public gener-  
ally. (Signed) David Farquharson, Wright & Sanders, S.

**NEW YORK METALLURGICAL WORKS,**

104 and 106 Washington St., N. Y.  
Branch, 318 Pine St., S. F.  
ORES CRUSHED AND SAMPLED, AND WORKING TESTS MADE BY ANY PROCESS, ASSAYING IN ALL ITS BRANCHES. ANALYSIS OF ORES, PRODUCTS, MINERALS, ETC.

Assaying and Metallurgy of Silver taught theoretically and practically.  
Examination of mines and the starting and running of reduction works a specialty. Telegraphic reports, of guaranteed accuracy, on mines and mills can be ordered from San Francisco House.

MATHEY, KUSTEL & RIOTTE, M. E., & Mfr.

SHEET IRON PIPE.

**FRANCIS SMITH & CO.,**

Manufacturers of

**THE PATENT CHANNEL IRON WHEELBARROWS.**

THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand.

**SHEET IRON PIPE.**

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Bolders, from 25 to 100 Gallons. Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

**PACIFIC MACHINERY DEPOT.****H. P. GREGORY & CO.,**

Nos. 2 and 4 California Street, San Francisco.

Importers and Dealers in every description of

**MACHINERY!**

Sole Agents for the Pacific Coast for

**BUCKEYE****Engine Company.**

J. A. Fay & Co.'s Wood-Working Machinery; Bement & Sons' Machinists' Tools; Blake Steam Pumps; N. Y. Belt- ing and Packing Co.'s Rubber Goods; Sturtevant Blowers and Exhaust Fan; Tanito Co.'s Emery Wheels and Machinery; Payne's Vertical Engines and Boilers; Perry's Centrifugal Pump; Judson's Standard Governors; Dreyfus Self-Starters; Gould Mfg. Co.'s Hand and Power Pumps; Eclipse Windmills; Dieston & Sons Circular Saws; Otto silent Gas Engine; Dues' Elevator Cams; Ballard's Oak Tanned Belting.

Also on hand and for sale A FULL LINE OF MILL AND MINING SUPPLIES.

**GOLD MINERS**

WORKING PLACER, GRAVEL AND QUARTZ MINES.

**SAVE YOUR GOLD!**

— BY USING —

**SILVER PLATED AMALGAMATING PLATES.**

The most economical and successful process now in use. Will warrant my Plates to save a very much larger percentage of gold than any other method.

SWING AND RIFFLE PLATES for Saving Float Gold Made to Order.

OLD MINING PLATES BOUGHT, TAKEN IN EXCHANGE FOR NEW, OR RE-PLATED.

ALL KINDS OF METAL GOODS PLATED!

**San Francisco Gold, Silver and Nickel Plating Works,**

653 and 655 Mission St., bet. New Montgomery and Third, San Francisco.

**STONE BREAKER AND ORE CRUSHER.**

The Dodge Rock Breaker CHALLENGES THE WORLD to produce as good and cheap a machine. Rock Breaker and Cornish Rolls Combined in one Machine. Pulverizers to granulate Ores for Roasting, chloriding, leaching & concentrating.

M. B. DODGE, 431 Fremont Street, S. F.

**NEW MINING FIELDS.**

Prof. Hayden's Geological survey of the northern wilds, comprising his explorations in the Big Horn, Gray Bull, Yellowstone and Sun River Countries, Wind River, Teton, Little Rocky and Bear Paw Mountains. Their geology and physical features. Where the survey found "paying prospects," going from 6 to 25 cents in gold to the pan. Immense gravel bars prospecting 8 and 10 cents per pan. Water abundant for hydraulic mining. Extensive gold and silver bearing quartz lodes, one mammoth ledge averaging \$18.90 in free gold per ton, from surface cropings. The classes of country rock peculiar to each section, which interest the miner, as being the most congenial for the existence of rich veins and placers. A valuable work (with map), forming a complete intelligible, systematic guide and companion for miners and gold hunters, desirous of prospecting in the northern Rockies and localities mentioned. Terms, \$5 per copy; 5 copies for \$20. Address J. A. CAMPBELL & CO., Evanston, Wyo. Ter. Box No. 119. [Mention this paper.]

**OTOKAR HOFMANN,**

(Of the Firm of Hofmann Bros.)

**Metallurgist and Mining Engineer.**

Erection of Leaching and Chlorination Works a specialty. Working Tests and Reports made.  
415 MISSION STREET, SAN FRANCISCO.

**SAVE YOUR GOLD AND SILVER.**

I am prepared to demonstrate, if miners will bring me from 500 pounds to a ton of their ores, that I can save from 25 to 100 per cent. more than any other machinery now in use. I will make no charge.

Machinery can be seen in operation every day at No. 143 Fremont Street.

## PATENTS AND INVENTIONS.

### List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," U. S. and Foreign Patent Agents.

FOR THE WEEK ENDING MAY 20, 1881.

240,953.—ANIMAL SHEARS.—J. J. Bogard, Tehama, Cal.  
240,963.—GATE.—A. P. Campton, Rohnerville, Cal.  
241,032.—PIPE MACHINE.—R. Layng, S. F.  
241,044.—CARBON TRAMWAY.—S. R. Mathewson, S. F.  
341,041.—HARVESTER.—D. C. Mattheson, Stockton, Cal.  
341,071.—BAG.—F. Roehner, Oakland, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

### Recent Decisions Relating to Patents, etc.

We give below brief abstracts of decisions rendered upon patent cases in litigation, for the benefit of our readers:

#### DECISIONS OF THE U. S. COURTS.

##### Potter et al. vs. Stewart.

U. S. Circuit Court, Southern District of New York. Decided January 22, 1881. Blatchford, J.

1. It is of no consequence that a re-issue states that certain combinations are found in the machine which will act in a certain way and effect certain results, when the original did not state that such combinations were found there, or failed to state that said modes of operation and said results would follow, provided the said combinations in fact existed in a machine made according to the drawings and descriptions in the original patent, or provided the said modes of operation and the said results in fact followed in a machine so made. To supply such defects is the very object and effect of a re-issue.

2. A combination claim may be infringed, although the specific devices used by the defendant were not known at the time of the patentee's invention.

3. Any improvement in an element of a combination which does not effect its manner of co-operation with the remaining devices, will not serve to avoid the charge of infringement.

##### Crouch, Appellant, vs. Roemer.

Supreme Court of the U. S. Decided October term, 1880. Appeal from the Circuit Court for the District of New Jersey. Chief Justice Waite delivered the opinion of the Court.

Shawl straps with handles attached to a leather cross-piece having loops at the ends being old, it is no invention to stiffen, by artificial means, the leather cross-piece, which had before been made as rigid as it could be by thickness, doubling and stitching. The use of known equivalents for some of the elements of form or structure, to make them somewhat better, is not invention.

##### Waring, Jr., vs. Johnson.

U. S. Circuit Court, Southern District of New York. Decided February 4, 1881. Blatchford, J.

1. Re-issue of Letters Patent No. 8,199, granted G. Waring, Jr., April 23, 1878, held to be valid.

2. When an invention is claimed as "the combination, in a check book, of checks and stubs" of substantially the same size, so united that two checks lie between only two stub-pieces, substantially as specified and set forth, it is immaterial, in view of the state of the art, whether the defendant's book has the line of perforation between the check and stub-leaf at the top or bottom of the stub-leaf, or at the leaf end of the check.

3. It will not invalidate the re-issue that the claim is broader than the claim of the original patent, provided that it is "for the same invention" shown and described in the specification and drawings.

\* More complete reports of the proceedings may be found on file in the office of the MINING AND SCIENTIFIC PRESS Patent Agency, 202 Sansome street, S. F.

### Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

**WHEEL.**—Ira H. Bradebaw, San Leandro, Cal. Dated May 10, 1881. No. 241,284. This improvement is particularly adapted to the construction of wheels which are used upon mowing and reaping machines, headers and heavy agricultural machinery. It consists in a novel construction of a wheel having a hub in which the spokes-sockets are formed alternately upon each side of a central disk, or flange, whereby the bases of the alternate spokes are entirely separated from each other, while their outer ends connect with the rim on line with each other. This leaves efficient space so that the spokes may be all made of a certain size and need not be tapered to fit the sockets. The sockets have flanges projected from one side to grasp the edge of the spoke to hold it. In combination with these sockets the inventor employs two exterior disks, one of which is formed on the box in which the axle turns. This box extends through a central hole in the spoke-socket portion of the hub, and the opposite flange slips over its end, being either screwed on or bolted through to the opposite disk, so that the two are drawn closely against the side of the spoke-sockets, which they close on the outer sides. The whole construction is simple, light and cheap, as the hollow shell forming the spoke-sockets and the box and flanges are easily cast, and the spokes themselves may be completed in the form of long bars, or twisted by machinery, and then sawed to the proper lengths and put into their places without further fitting.

**ROLLER SKATES.**—Wm. Akin, S. F. Dated May 10, 1881. No. 241,270. This invention relates to certain improvements in roller skates of that class in which the roller frames are supported upon axles which stand at angle to a horizontal plane, so that when the foot-stand is turned to one side, the rollers upon that side will be cramped, or drawn nearer together, and the skate will thus be caused to run on a curve.

The roller frame is so constituted that a single roller may be used at each end of the skate, and entirely surrounded or inclosed by its frame; and ball-and-socket joints are formed, upon which the roller frame turns, to give the angle by which the skate is caused to run in a curve. The socket next the foot-stand is deeply concave, so that the ball stands as high as possible, which is of great advantage, as it gives the roller a greater throw to each side and greater facility in turning. The rubber or other elastic returning spring is fitted upon the shank of the ball-joint and sets in the concave below the head or ball. It is regulated so as to give greater or less stiffness of action by means of a screw at the opposite end of the roller frame, and by which it is compressed or slackened. The rollers are made broad, and by the method of construction the whole frame is greatly strengthened.

**FILTERING FAUCET.**—W. M. Sack, Oakland, Alameda county, Cal. Dated May 10, 1881. No. 241,427. This invention relates to a filtering faucet, in which a peculiar construction and arrangement of the faucet render it self-cleaning. The object is to provide a self-cleaning filter faucet, to avoid the necessity of taking the filter out. A filter is placed in the faucet, and is so arranged that by turning the cock in reverse positions the water is passed first down and then up through the filter, the latter being thus cleaned at each reversal of the water.

**AYERLL MIXED PAINT.**—It would hardly seem that the simple idea of preparing ready-mixed paint for general sale would create such a revolution in the use of paints as it has done. Before the Ayerll mixed paint came on the market, people had to buy lead, oil, color and driers, separate and mix the paint themselves. As this required skill, few attempted it, but hired painters to do the work. Now, however, any small job of painting can be done by mixing a quantity to suit of Ayerll paint, which is ready mixed and prepared for use in any color. It is also purchased in large quantities by consumers who get a paint of uniform grade of excellence. This pioneer in mixed paints is improved by pure linseed oil, pure white lead, pure zinc and the best colors for tinting, which, by the patented process of manufacture, are united to produce a paint which is at once beautiful and durable. The "soluble glass" uniting the oil and pigments, the whole mass dries with a hard, rich, glossy appearance; and it will not chalk or peel off. The paint can be scrubbed or washed as occasion requires, when its freshness will be renewed. At this office of the general agent for the Pacific coast, O. S. Orrick, 403 Market street, we recently had occasion to note the great variety of colors and tints in which this paint is now mixed. Every possible shade is prepared, and it is put up in large or small packages, so one can procure the exact quantity required, without loss from waste.

**ATOMIC WEIGHT** is the weight of the atom of an element as compounded with that of the atom of another element, ascertained from the proportions by weight in which they combine; or, leaving out of view the hypothetical idea of an atom, it is the number expressing the proportions by weight in which the elements combine—one of the elements, either hydrogen or oxygen, being assumed as the unit for comparison with the others. Oxygen and hydrogen combine to form water in the ratio of 1 hydrogen to 8 of oxygen; and 1 and 8 are therefore the combining proportions of hydrogen and oxygen—also called, to avoid hypothesis, their combining equivalents.

**WASHINGTON COLLEGE.**—The examination of the classes in Washington college, Alameda county, Cal., will take place on Monday, Tuesday and Wednesday, May 23d, 24th and 25th, commencing at 9 o'clock each morning. The last hour of Monday and Tuesday will be devoted to declamations, reading of compositions, and to music. Wednesday afternoon, from 1 to 4 o'clock, there will be declamations, reading of essays, vocal and instrumental music under the direction of Profs. Toepke and Brandau. The graduating exercises will be held on Wednesday evening, May 25th, commencing at 7:30 o'clock. The friends of the institution, and of education generally, are cordially invited to attend all the above exercises.

**COMPLETE HARVESTERS.**—Mr. W. J. Little, of Stockton, will have in operation this year five or more of his new harvesters, upon which he has lately added important improvements. They vary in size, according to width of cut, from 16 to 24 ft. Mr. Atwater, of Merced, last year cut and threshed an average of 50 acres per day with this machine in average grain, and will run two of the machines this year. Mr. Ostrander, of Merced, and Mr. Kohl, of Placerville, will use the Little harvester this year for the second season. Mr. Little has important improvements this year, and his harvesting apparatus is worthy the attention of wheat growers.

**JAS. H. MILLER,** Tucson, A. T., wishes to learn the whereabouts of Alphonso Miller and sister, who were in Marysville, Cal., in 1866.

In Sierra county the Howland Flat mine is paying regular dividends to its Scotch owners.

### Mining Items.

THE different mines in Cave Creek, 30 miles northeast of Phoenix, are being developed rapidly and showing well.

THE Tiptop mine, 40 miles north of Phoenix, has turned out, with a 10-stamp mill, over \$100,000 in the last two months.

CHINESE wood choppers in Montana have been driven out of the woods by white men, mostly Frenchmen.

Flow of water at the mouth of the Sutro tunnel is 4,342,896 gallons in 24 hours. Temperature of the water is 120°.

JOHN POLGLASE, late underground foreman at the Idaho mine, has been presented with a handsome cane by his brother miners.

THERE is not a mining company in operation in Pioche, but there has been \$60,000 worth of bullion extracted from the chloride ores taken from the mines in less than two months.

It is stated that the Union Con. mine, of Cerro Gordo, Inyo Co., together with the furnaces, has been leased by San Francisco parties, and that work will soon be commenced on this property.

RICH placers have been discovered a few miles east of Vulture City, Arizona, paying from \$40 to \$50 per day. Numbers are rushing to the new El Dorado. Vulture City is 60 miles northwest of Phoenix, and in the direction of the Vulture mine and 80-stamp mill. So says a dispatch.

AT Angels camp a new feature in hydraulic mining has been introduced. It is the electric light, which so illuminates the whole field of operations as to enable the work to proceed at night with all the safety and carefulness which attends it by sunlight. Considerable mining is opening up here. Men are prospecting and arastras are running in many places.

THE Yreka creek mining enterprise, in Oregon, one of great magnitude, is likely to prove a failure, from various causes. A great amount of money has been expended in it by capitalists of San Francisco and elsewhere, and, if this is the case, the loss must be heavy. Last winter's storms almost destroyed a great portion of the large ditch, and other misfortunes have not been few.

**BEVERIDGE GOLD YIELD.**—The statement in the last issue of the Inyo Independent of the shipment of over \$14,000 in gold bullion from the Beveridge mines, being the product for the month of April, should attract the attention of parties seeking productive gold mines. Beveridge is fast coming to the front as a rich gold producing district. A number of fine gold quartz ledges in this camp are as yet untouched.

THE Ward Reflex is now assured that the proposed Eureka and Colorado river railroad will not be built. The road from Stockton, Utah, to Eureka, will answer all the purposes of the projectors of the Eureka and Colorado river railroad, as it will cross White Pine county fully as far south as there was ever any intention of extending the Eureka and Colorado river railroad.

**CROSS LEDGES.**—Where two or more ledges cross or intersect each other, priority of title governs, and such prior location is entitled to all ore or mineral contained within the space of intersection, but the subsequent location has the right of way through the space of intersection for the purpose of the convenient working of the mine. And where two or more veins unite, the oldest or prior location takes the vein below the point of union, including all the space of intersection.

**GOLDEN BASIN.**—This is the name of a comparatively new mining district in Arizona, located about 50 miles due east of El Dorado canyon, which is of great promise and will at an early day attract considerable attention of the mining world. The ledges are principally gold, containing little or no silver whatever, and varying in width from two inches to four feet, the assays ranging from \$10 to \$50 in gold. The country around is well timbered and there is an abundance of water for milling purposes 12 miles from the mines.

In the matter of the Richmond-Albion decision, Judge Rising wishes it to be understood that he decided that the St. George patent, owned by the Richmond company, was unlawfully issued, and upon the trial of this case, must be decreed to be the property of the Albion company; but because the matter heard before him was solely as to whether the injunction should continue or be dissolved; and as he had no power to set aside the patent on such hearing, for that reason alone he continues the injunction. We should regard this as a decided expression of legal opinion in favor of the Albion.

In the suit of the Empire gold mining company against the Pacific gold mining company, Chief Justice Morrison R. Waite, of the Supreme Court of the United States, Thursday, ordered that an attachment issue in the case. Yesterday the United States Marshal made his return on the writ, showing that he had attached the Oaks quartz mine, 1,200x500 ft., on the lode of and adjoining the Empire claim, at Plymouth, Amador county, known as the Pacific Gold Company mine. The action is to recover \$120,000, and the bonds required over this amount and damages that might result from the attachment.

### News in Brief.

BOSTON talks of undertaking a world's fair in 1885.

THREE thousand immigrants arrived in New York on Sunday night.

THE Mexican Congress Committee on Public Works reported favorably on Gen. Grant's railway contract.

SINCE the Kansas Prohibitory Liquor Law went into effect, it is said, nine-tenths of the liquor saloons have closed.

THERE is great want and misery in the State of Bolivia in consequence of the ravages of locusts on the cereals—especially rice and Indian corn.

It is said the Queen desires to confer a peerage upon Master Conigebay Israell, nephew of the late Lord Beaconsfield, but Gladstone dissents.

THE California Southern railroad at San Diego, Saturday, called for bids for 30 miles additional, making in all 82 miles let since December 10th.

A BILL will be presented in the German Bundestag regulating the employment of boys in mines, stipulating that their hours of labor must not exceed eight per day.

In London the crowd of persons on the lookout for investment has not lessened, and even the Spanish and Peruvian bonds are looking up. Sound American securities are dearer.

THE complaints respecting the condition of emigrant vessels have led the English government to dispatch Capt. Wilson to Queenstown to inquire into the correctness of the statements.

THE Swiss representatives abroad have been instructed to ascertain the views of the various States, relative to the adoption of an international law regulating hours of labor in the factories.

ST. PETERSBURG advises say the Emperor has accepted the resignation of Gen. Melnikoff and has appointed Gen. Ignatieff to succeed him. This change has produced great uneasiness in political circles.

JAMES ALEXANDER FORBES, who came to California in 1829, died at Oakland last week. He at one time owned one-eighth of the Almaden mine. He was author of Forbes' History of California, a standard authority.

THE engineers engaged in the work of constructing this ship canal across the Isthmus of Panama, at last advise that a shaft 100 ft deep, where the Chagres river dam is to be begun, and had not yet reached bed rock.

MAY 5th no river boat had left Bismarck for Benton. The wood yards the whole length of the Missouri have been washed away, and no dry wood can be got. Boats will have to bring their own coal or stop to cut wood.

GLADSTONE'S difficulties increase daily. The Transvaal affair has apparently sunk deeply into the minds of the people, and the present attitude of the Boers is regarded as extremely menacing to British interests in South Africa.

A NEW line of railroad is to be constructed from the main line of the Missouri-Pacific at the Pacific junction, to Carthage, Mo. This line will open up a new and very rich section of Missouri and will shorten the through line to Texas by about 30 miles.

ADVICES from Paris say that *La Liberte* announces that Col. Flatters' Trans-Sahara Mission will be taken up, and the murder of Col. Flatters and his followers avenged. The new expedition will consist of a regiment of 700 men mounted on camels.

GOV. OVERTON, of the Chickasaw nation, has gathered together an army of 300 men, and has issued an order that Texas cattle raisers, and whites men generally, must leave the country before June 1st, or force will be used. A similar situation prevails in the Choctaw nation.

SUIT has been brought in the Superior Court at Oakland by the Savings and Loan Society against the North Pacific railroad company, to recover the sum of \$150,000 on a promissory note. Plaintiff holds 450 of the first mortgage bonds of the denomination of \$1,000 as security, and seeks to recover on them.

RAILWAY workmen at Ekaterinastat, Russia, have pillaged the shops of several Jews. The arrival of troops stopped further rioting. Order has also been restored at Nonolop and Ananief. There have been anti-Jewish disturbances at Warsaw. The Jews at Odessa have been ordered to surrender their arms.

At the moment when the Greek question appears to be settled, a distressing telegram comes from Athens. It is asserted that the Porte, covertly assisted by Austria and Germany, intends to prevent a peaceful settlement. It is stated further, that England's isolation encourages the three Empires to settle the Balkan question. The Bulgarian troubles are associated with this idea.

PANAMA advices of May 7th state that Frederick Ford, a British subject, and representative of the famous house of Dreyfus Bros. & Co., Paris, was arrested recently in Lima by the Chilean military authorities and held a close prisoner for 25 hours. He was released only after energetic representations on the part of the English Minister Resident. The only crime alleged against Ford was that Piorola had addressed him a personal letter, which was intercepted and fell into Chilean hands.

## Iron and Machine Works.

**SACRAMENTO BOILER WORKS,**  
214 & 216 BEALE St. (rear of Etna Foundry),

**J. V. HALL,**

**PRACTICAL BOILER MAKER.**

Marine, Stationary and Portable Boilers, Smoke Stacks, Hydraulic Pipe, Oil or Water Tanks, Ore and Water Buckets, Gasometers, Girders, Bridges and Iron Ship Building.

**Patent Agency.**

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address **DEWEY & CO.,** Patent Agents, 202 Sansome St., S. F.

### EXCELSIOR BLASTING POWDER

MANUFACTURED BY THE  
Excelsior Powder Company.

This is no so-called "safety" Powder, but a powerful explosive, and as safe to handle and use as any nitro-glycerine Powder on the continent. There is no headache or nausea in the use of this Powder, as the noxious fumes are entirely done away with. It is put up in cartridges of any size to suit consumers and is exploded with cap and fuse, the same as any other high explosive. The following testimonial is a sample of hundreds of the same tenor being constantly received.

GOLD HILL, August 17, 1880.

AGENT EXCELSIOR POWDER CO.—Dear Sir,—I have used your Powder in test cement and hard blasting rock, and find it superior to any Powder in use on the Comstock. It does its work effectually, and does not leave the person using it with a severe headache, like the other Powders do to the majority of miners. In recommending it I would suggest, give it a fair trial and I am confident it will speak for itself. Wishing your Company success,  
I am respectfully yours, etc.,

GEORGE CLARK,  
Foreman Sierra G. and S. M. Co.

### \$1,000 CHALLENGE!

### THE FRUE ORE CONCENTRATOR.

Over 250 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal. Saves from 50 to 100 per cent. more than any other Concentrator in use, and the concentrations are clean from the first working.

The wear and tear are merely nominal; the water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of \$1,000 each, and we mean business.

ADAMS & CARTER, Agents, Room 7, No. 109 California Street, S. F.

FOR SILVER, LEAD AND COPPER ORES WITH NEW AND IMPORTANT IMPROVEMENTS HAVING FOR MANY YEARS MADE A SPECIALTY OF THIS LINE OF WORK, AND CONSTRUCTED, WITH FEW EXCEPTIONS, EVERY SMELTER IN USE ON THIS COAST, WE ARE PREPARED TO GUARANTEE MUCH BETTER RESULTS THAN CAN BE OBTAINED FROM THOSE OF ANY OTHER MAKE, AND THE BEST RESULTS POSSIBLE ON ANY CLASS OF ORE. SEND FOR CIRCULAR RANKIN, BRAYTON & CO., PACIFIC IRON WORKS, SAN FRANCISCO, CAL.

# MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO.,  
Publishers.

SAN FRANCISCO, SATURDAY, MAY 28, 1881.

VOLUME XLII  
Number 22.

## A Siphon Mining Sluice.

In the stamp mills in common use in the mining sections, the mills are divided up into batteries containing five stamps each. Any desired number of these may be placed in line, and in front of each one is a series of amalgamating plates, over which the material flows into a sluice, the sluices from all the batteries leading to a common sluice, into which all discharge. The main sluice conveys the tailings away to the place of deposit. Notwithstanding the precautions which are taken, a certain portion of the precious metals escape with the tailings into the sluice, and is lost.

The object of the invention illustrated on this page (which was patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by Joseph M. Robinson, of Eureka mill, Plumas county, California), is intended to reduce this loss by placing at the end of the main sluice a peculiarly constructed sluice-section, through which the material must all flow, and in which the escaping particles of gold, quicksilver, etc., are caught and saved. In case there are pans in use in the mill, their tailings are also conducted into the main sluice to be conveyed away from the mill, so that all the material passing away has to pass through the sluice section before it can escape.

At the end of the main sluice is placed the curved sluice-section A, it being mounted on an axle or shaft which fits in the bearings or boxes as shown. At the upper end of this sluice-section is a hopper B, into which the tailings flow from the main sluice, and below this hopper is a trough, C, a foot or more deep.

From this trough the sluice-section inclines upward, as shown, to the neck of this section, and thence it inclines downward sharply, the whole being somewhat of a siphon shape. At the outer or lower end, which is considerably lower than the hopper and trough, is a gate controlling the flow from the sluice. If the water from any one of the batteries is shut off at any time, this gate in the discharge pipe can be closed a little, so as to keep the section full of water and sealed from the air.

If, for instance, the trough of the section is a foot deeper than the hopper, and the distance from the bottom of the trough to the bottom of the neck, or highest point to which the water must rise to escape down the discharge portion, is also a foot, and the lower end of the discharge pipe were on a level with the hopper, said hopper being the height of the neck, the water would flow through the section of its own volition; but when sand, tailings, etc., are brought into the sluice with the water, this will settle at the bottom and remain there, because there is no force to throw it out and the section would become choked.

To prevent this, the inventor strengthens the discharge pipe considerably and brings its lower end lower than the hopper, the siphon principle being then brought into action to relieve the sluice and draw the material with the water up the incline to the neck, where it passes down and out. Any desired length may be given to the discharge pipe, enough only being required to throw out the sand and light sulphurets, leaving the gold and particles of mercury, heavy sulphurets, etc., in the sluice.

This platform on which the section stands is so placed that the hopper will come under the end of the main sluice from the wall, and low enough, so that the end with the hopper may be raised or depressed at will. When one end is raised the other end is correspondingly depressed, which motion will regulate the working of the machine to a certain extent. This is rendered possible by the section being mounted on the axle, as shown, so it may be oscillated at will. The block D, under the hopper, is removable, so that blocks of different sizes may be substituted to regulate the inclination of the section.

As the material passes into the sluice section, on dropping from the hopper into the trough, it is compelled to move up the incline with the current. The lighter particles do this easily; but the quicksilver globules and heavier particles of gold and other precious metals, by their gravity, will remain below and not rise upward,

being caught in the sluice. If the water is not allowed to run over the hopper, the floured quicksilver will remain on top of the water in the hopper until an aggregation of particles takes place, when it will gravitate to the bottom of the sluice, and be saved the same as gold or other heavy material.

In starting the sluice the hopper is raised a little above the neck; and, by having a gate in the end of the main sluice, this gate will, when

MINING SLUICE FOR QUARTZ MILLS.

closed a moment, gives a head of water sufficient to crowd it through the section and force the air out of the discharge pipe. The siphon being thus started, the long column of water will continue to draw the material up the incline of the section as long as the supply is continued.

Power is thus gained sufficient to draw the tailings through the incline sluice without drawing out the precious metals. The water has an

THE KNIGHT WATER WHEEL.

easy and even flow through all parts of the sluice alike, and the user can, of course, apply any amount of power equal to atmospheric pressure, or as little as he desires, the inclination being regulated as well as the flow through the section.

The Virginia City Enterprise says: In all directions we hear of laborers being wanted to do various kinds of work. This is rough on the tramps. They are quite bewildered, and hardly know in what direction to send their steps to avoid stumbling upon a place where they would find work staring them in the face.

The profit of copper mining in the Walker River, Nev., region now appears to be an established fact. There is room and occupation there for a dozen furnaces.

## The Knight Water Wheel.

The Knight, as a pressure wheel, having obtained a success seldom equaled by any new invention in its line, we give in this issue a cut showing in part the style of it as near as a cut can, that those who have water for power may be able to form some idea of it.

Of these wheels, there are now running quartz

calculated for it from actual tests. The wheels are made of all diameters, according to work required. The face of buckets also vary, but usually run from three to six inches, according to wheel.

Some very important improvements have lately been made in the nozzle, which forms one of the important features of the wheel. This is in the addition of what may be termed a hydraulic engine, making a complete regulation of the power, and all can be operated 200 ft. from the wheel. This addition allows the introduction of six openings as water discharges, instead of three as formerly. This improvement is more particularly used on low heads and larger bodies of water. For hoisting works it is universally used. This new feature is not represented on the cut, as the patent on this is in course of issue through the MINING AND SCIENTIFIC PRESS Patent Agency, but will be illustrated in due time. These wheels are manufactured by Knight & Co., Sutter Creek, Cal., Almarin B. Paul & Co., office room 20, Safe Deposit building, San Francisco, Cal., and Fraser & Chalmers, No. 139 Fulton street, Chicago, Ill. By writing to any of the above firms all desirable details can be had.

## Sliding Scale for Mines.

They have a great deal of trouble in England with miners' strikes. The men get small wages and see no chance of advancement of any kind, while they have plenty of laborious, tiresome work. All sorts of plans have been suggested to ameliorate the condition of the men and to prevent the repetition of disastrous strikes. Employers have been asked to make concessions to the men, and the men to make concessions to the employers. The question has been discussed in all its bearings. A national conference of miners' representatives has just been held at Birmingham, at which it was decided to adopt a sliding scale as the best means of preventing strikes and lock-outs.

It is interesting to note that it was stated at the conference alluded to, which represented about 195,000 miners, that at the present time there are about 180,000 miners working in mines on regulations of some kind or scale, but many of them, it was stated, are so dissatisfied with their working that they are about to give notice to have them put on a different basis, the north of England miners being amongst the number. It was resolved that all the associations or bodies of men who are bound by a sliding scale should forward a copy of such scale and the regulations attached to it to Mr. Macdonald, M. P., with a view of his suggesting the basis of some scale or method of payment which would be more satisfactory to the miners employed. Another resolution was agreed to, to the effect that the conference thought that accountants ought not to be bound to secrecy, but should be allowed to give some details to the representatives of the men to show and convince them that the work had been got satisfactorily through.

QUARTZITE AND QUARTZ.—The Richmond Co. of Eureka, Nevada, in sinking the last 200 ft. of their main shaft, cut through the limestone zone and penetrated the quartzite; since sinking was resumed some 50 ft. has been made. The Eureka Sentinel, now announces that the barren quartzite has given way to an almost pure white quartz carrying a fair amount of metal. Assays average right along \$30 per ton. It is a magnificent article of flux, and now the ore taken from the shaft is being saved in the dumps for shipment to the reduction works. This is an entirely new feature in mining on Ruby Hill, and may add untold wealth to the mines of that portion of the district. Further developments will be watched with no little interest. If the whole quartzite belt should change at that depth to paying quartz the mines would become practically inexhaustible.

REPORTS from Paradise are to the effect that a fine body of rich ore has been cut into in the face of the drift in the Wild Goose. It is said to be a richer and larger body than any heretofore found in the mine.

THE Hansuer smelter, Utah, is running steadily and producing excellent hullion.

We admit, unendorsed, opinions of correspondents.—EDS.

made a change for the better in that camp.

## MECHANICAL PROGRESS.

## Iron as a Plastic Material.

The original method of forging iron by the simple application of the hammer, continued and varied until the desired form was given to the product, was largely improved upon by the introduction of drop-forging. By the use of a die or matrix, and the weight and gravitation of the powerful hammer falling upon the iron, it was made to assume almost instantly the shape required under the immense force thus brought to bear; and for a great number of processes this method has been found entirely satisfactory. Not only was the rate of production vastly increased by this advance of the art, but the quality of the manufactured article, as to the condition of the fiber of the metal, where there is not too radical a change from the original form of the bar, has proved to be all that its practical use and service requires.

In the exceptional cases just hinted at, however, it was perceived that a still finer adjustment of cause and effect was demanded to meet the necessities of the case. If the change of form is such that the percussion of the hammer in drop-forging destroys the fiber of the iron, the result is a failure, so far as the quality of tenacity is concerned. How to meet this difficulty, and apply the necessary amount of force without the destructive effect of the sudden stroke, has been a perplexing question. To administer the blow, and yet preserve the continuity of the fiber, was an evident impossibility. How, then, should the requisite degree of power be employed upon the iron so as to give it the form of the mold, yet without disintegrating its metal itself?

The solution of the problem has been found in treating the iron as a plastic substance, which it in fact becomes when heated to a certain degree—something less than a welding heat, and very far below a fused condition, but still imparting to it sufficient mobility to serve the purpose. In this state it is subjected to enormous pressure, steadily yet rapidly acting, and forcing it into the matrix with irresistible effect, inasmuch that when the product of this compressive forging is examined, it is found to be not only perfect in shape but unbroken in fiber, and therefore having all the toughness which it possessed in the bar. The work is done with speed, and thus far there is no dissent from the verdict of approval with which the results have been received by the iron-working community. The new process is perhaps not strictly a discovery; it appears to be rather the fruit of a closer knowledge of the metal with which it deals, and a more accurate determination of the precise state in which it will submit to be treated as a fluid while still retaining its texture as a solid substance. "Getting it down to a line point" is a phrase from the vocabulary of the street; but it gives in few words the exact nature of this latest achievement in the art of iron-working, and indeed of most of the substantial victories which science is daily winning for mankind.—*Industrial World.*

**MANGANESE BRONZE FOR PROPELLERS.**—*Design and Work* states that the Lords of the Admiralty have ordered the *Colossus*, now in course of construction at Portsmouth, to be fitted with a manganese bronze propeller, in place of the one of gun metal, originally ordered. This decision has been arrived at after a series of comparative experiments made with the two metals in the presence of Mr. Farquharson, of the Admiralty, at the Works of Messrs. Maunslay, Sons & Field, the contractors for the engines. Bars of both metals, one inch square, were placed on supports 12 inches apart, and first subjected to a steady pressure applied in the middle of the bars, and afterwards to impact by a weight of 50 lbs. falling from a height of five ft. With a steady pressure the gun metal bars dipped between the supports, or broke with a strain of 28 cwt., while the manganese bronze bars required 54 cwt. to break them. Tested by impact, the gun metal bars broke with from 8 to 9 blows, while it took from 13 to 17 blows to break the manganese bronze bars. The ultimate bend of the latter was also in both cases more than that of the gun metal, showing nearly double the strength, with superior toughness. The advantages claimed for manganese bronze over gun metal are, first, a considerable saving of actual weight of machinery, and secondly, that it enables a thinner, and consequently a better, blade to be made, offering less resistance to the water, and equalling in strength the gun metal blade of greater dimensions.

**BOILER PATCHES.**—A mistake is often made in making a boiler patch of thicker metal than that of the shell of the boiler needing it. A common reflection ought to show the absurdity of putting a five-sixteenths or three-eighths patch on an old one-quarter inch boiler shell; it is not so rare an occurrence as one would imagine. A piece of new iron three-sixteenths of an inch thick, will, in most cases, be found to be stronger than that portion of a one-quarter inch old plate needing repairs.

**STAINING WOOD GREEN.**—To half a pound of the heat verdigris add one ounce of indigo; boil six pints of vinegar. Allow the veneers to immerse till the color has penetrated.

## The Gilchrist Basic Process in America.

The *Industrial World* says: The fact that the Bessemer Steel Association has purchased, for \$400,000, the American right to the Thomas-Gilchrist basic method for dephosphorizing iron, should have a stimulating effect upon the inventive genius of this country, especially in metallurgical circles. It is evident that the association intend to keep the steel rail production under their own control, and any new process that will rival the Bessemer or the Thomas-Gilchrist processes, will find a ready and liberal purchaser in the association. In any event, if the steel rail manufacturers would not become purchasers, there is plenty of capital ready to back up a new invention in this direction, if it can satisfactorily demonstrate its worth. It is not too much to assert that we are on the eve of great discoveries in the methods for manipulating the metals. The great advancement already made we trust is but a prelude to that greater progress which we shall yet see in this boundless domain of scientific research. No laurels can be taken from the brows of men such as Sir Henry Bessemer, Siemens, or Gilchrist, but honor and renown is reserved for other workers who shall either hew out new paths into the heart of the metallic world or carry on still further those already marked out by the men we have mentioned, and by other noted metallurgists of our times.

**STARTING FRICTION.**—When a shaft bearing is at rest in its box, the oil is pressed out from under it; either out of the box altogether, or upward to the space above the shaft, between the shaft and box. No doubt the metal of the shaft then settles down to actual contact with the metal of the box. In starting a lot of machinery into motion, the metal of the shaft must actually drag, for a short distance, in contact with the metal of the box, making the machinery hard to start. But as the bearings make part of a turn in their boxes, the oil adhering to the surface of shaft bearings is dragged in between the box and shaft underneath, thus floating the bearing upon a sea of oil. This sea is, however, not very broad or deep, but there can be no doubt of flotation. As flotation takes place, the bearings rotate more easily than when the metal drags in contact. This explains why starting friction is greater than friction of motion in the machinery. When heavy pressures are brought to bear at the boxes, the oil is hindered from entering freely between the surfaces; and if, at the same time, the two surfaces are not nearly parallel, there may possibly, or even probably, be metal contact at the prominences. The high resistance thus caused will produce heat at the rubbing parts, which, by continuous motion, is sure to become excessive, resulting in destruction of lubricant, abrasion of metal surfaces, waste of power, etc.

**TORSION.**—If we know the force in pounds per square inch that it takes to shear any material, then that required to break a cylinder of it by torsion would be the leverage in inches, divided into half the shearing force in pounds per square inch, times 3.1416 times the cubic root of the cylinder area in inches. A square shaft is about one and one-fifth times as strong against torsion as a round one, and one-fifth less than a round hollow one of the same sectional area. Hollow shafts resist torsion better than solid ones of the same area of metal. Wrought iron shafting, supported at eight or nine ft. intervals by self-adjusting hangers, may have a diameter equal to the cube root of the number of horse powers it transmits, divided by the revolutions per minute and multiplied by 125. The faster shafting revolves when transmitting a given number of horse powers the less the torsional strain.

**A NOVEL KIND OF WIRE BELTING.**—Herr J. Jarolimek, of Hainburg, Austria, has brought out a novel kind of wire belting, which is described as follows: The wire is wound on spindles, the diameter of which is as small as practicable, and is obtained, therefore, in the form of a long spiral spring. *Der Techniker* states that the main point to be observed in using these wire coils is to give them dimensions proportioned to the power to be transmitted, so that while flexible, they do not suffer undue elongation when in use. Practical trials have proved that the proper proportion between tenacity and elasticity of these coiled wire strings is obtained when the spindle, around which it has been wound, has a diameter equal to that of the wire. The two ends of a string are hooked together, and each string (the number varying according to the power transmitted) is laid in a groove on the pulleys. This method of transmission is reported to be cheap and effective.

**METALLIC BELT.**—An inventor in Hartford, Conn., has patented a belt which is made of iron wire, the selvages being brass and copper. The web is of cotton, several threads being woven in without being twisted together. A double fabric is made, between which, or inside of which, a number of single heavier wires are enclosed to take the tensile strain of the belt.

**RULE for calculating the pressure of steam on a cylinder boiler at any given number pounds of steam:** Multiply the diameter in inches by the length in inches and by the pressure per square inch; the result is the total pressure tending to rupture the boiler.

## SCIENTIFIC PROGRESS.

**BEHAVIOR OF METALS IN SOLIDIFYING.**—The question is again before scientists for discussion: Whether the expansion of bodies on heating and contraction on cooling occur, as a rule, in the passage from the solid to the liquid state, and vice versa. Ice, it is well known, behaves differently, and is regarded as an exception. Kopp's researches have shown that phosphorus, sulphur, wax, stearic acid, stearine, chloride of calcium, phosphate of soda, hyposulphate of soda and Rose's metal grow larger in volume when fused. Observations made in the past concerning metals give very discordant results, and therefore Nies and Winkelmann have lately studied the question anew. As a foundation experiment, the solid metal was put into the fused metal. In certain cases the difference of density could be measured. For instance, tin, in solidifying, is increased in volume 0.7%; zinc is increased 0.2%; solid bismuth is fully 3% less dense than the fused metal. Expansion in solidifying was also demonstrated for antimony, iron and copper. Indecisive results were obtained with lead and cadmium; lead presented difficulties in the probably very small difference of density as a solid and as a liquid, its small heat conductivity and heat of fusion; and cadmium in the fact that in fusion it passes first into a viscous state. Thus, of the eight metals examined, six distinctly showed expansion in solidifying, and expansion may occur in lead and cadmium. If these experiments stand good, expansion would seem to be the rule for metals.

**THE VARIABLE COLOR OF SALICYLATE OF SODA.** The changeableness of remedies, whether in taste, effects or color, is an important thing to guard against. The first may be due to negligence, and often to carelessness, but the latter, or a variability in color, is rarely the fault of the dispenser, but of the manufacturing chemist, and at times depends on certain influences over which the pharmacist has no control. Salicylate of soda is of the latter class, sometimes occurring as a snow-white powder, and again of a dirty gray and even brown color. We find an explanation as follows: Whenever salicylic acid is brought or left in contact with an excess of an alkali, the mixture turns brown verging on a black. We do not know that any one has yet ascertained the exact cause of this change, but such is the fact. Manufacturers have to exercise the greatest care to prevent the point of neutralization being overstepped in the preparation of these salts; in fact they prefer, in order to insure a white salt, to have a trifling excess of salicylic acid present.—*Pac. Med. and Surg. Jour.*

**THE POLYSCOPE.**—At a recent soiree in the Paris Observatory, M. Trouve showed a live fish with its body lit up from within by his polycope, a minute form of which, with conducting wires passing to the hands of the operator, the animal had been caused to swallow (comfortably, let us hope). The whole body became transparent in the dark, so that the vertebrae could be counted and all details examined. This instrument promises to have many uses. Among others, it has already been applied, *La Nature* says, to show students the texture of the rectum and bladder; to facilitate extraction of a projectile at the back of the nose, to examine the stomach of a hull (in which a gastric fistula was formed), to lighting the interior of shells and cannon for examination, also to lighting powder magazines, in which case the reflector is inclosed in a triple envelope of glass.

**EFFECT OF COLD ON MAGNETIZED STEEL.**—A recent investigation conducted in the physical laboratory of Harvard University has led to the discovery of the remarkable fact that intense cold can deprive magnetized steel bars of nearly all the magnetism which may have been imparted to them. The intense cold was produced by solid carbonic acid. This fact has an important bearing upon observations of the earth taken in high latitudes; for what appear to be daily and yearly changes in the earth's magnetism may be due in large part to conditions of temperature, which effect the magnets used in the observations. It also must be concluded that the molecular condition of steel is changed by great cold.

**CHANGES IN WATER-LEVEL OF LAKES IN OREGON AND CALIFORNIA.**—A letter to the editors from Mr. B. F. Dowell, of Jacksonville, Oregon, states that Goose lake, 30 miles long and two-thirds of it in Oregon, the rest in California, was almost dry in 1853 and 1854, while in 1869 and 1870 there were 10 feet of water; its depth has been increasing since 1870, and there is a probability of its discharging, as at some former time, into Pitt river. Clear Lake also, about two miles farther south, is 10 feet deeper than it was in 1833-4; and Tulie lake, in the same region (the locality of the lava beds where were the hiding places of the Modoc Indians) is 10 or 15 feet higher to-day than then.

**HYDROBROMIC ACID AS A REAGENT FOR COPPER.**—A drop of the solution in question is placed in a watch-glass, a drop of hydrobromic acid is added, and the mixture is evaporated at a gentle heat. When it is reduced to the hulk of one drop, a rose-red coloration appears, three or four times more intense than that produced by potassium ferrocyanide. In this manner 1-100th milligram copper may be detected.

**SELF-LUMINOUS PHOTOGRAPHY.**—According to the *Photographic News*, self-luminous photographs are attracting much attention in Vienna. When these are examined by daylight they look like ordinary paper photographs, but in the dark they are beautifully phosphorescent in the high-lights, have a more or less feeble glow in the half-tones, and in the deep shadows possess no luminosity. The preparation of these self-luminous photographs is very simple. A silver print on albumen paper, or a collotype is rendered transparent by brushing over it a mixture of equal volumes of castor oil and oil of turpentine. The superfluous oil is removed by means of cotton-wool or a linen rag, and the phosphorescent paint is then put on. The paper thus prepared is then dried, and afterward mounted with its reverse side on cardboard. As soon as it has been exposed to the daylight and the light penetrates the transparent or semi-transparent parts, the phosphorescence of the luminous paint underneath is excited, and in the dark the image is seen with all its gradations. Brilliant pictures and moonlight landscapes give especially good results.

**A NOVEL PHENOMENON.**—Dr. Phipson, an English chemist, describes a novel phenomenon observed in connection with a zinc white of a dazzling purity, obtained by precipitating a solution of zinc sulphate by means of barium sulphide, submitting the precipitate to strong pressure, and igniting it with limited access of air. If any barium sulphide escapes oxidation, the white compound, on exposure to the sun, begins to darken, and in about 20 minutes becomes of a dark slate color. If removed into a dark place it gradually loses color, and in about five or six hours it becomes again snow-white. This experiment may be repeated with the same specimen as often as desired. Further, this change of color does not take place under a slip of common glass, whether thick or thin; at most the compound takes a slight yellowish brown color on exposure to the sun for two hours. The sample on analysis was not found to contain silver or any other substance known as antic.

**CHANGES IN THE DIAMETER OF TRUNKS OF TREES.**—According to the *Gardener's Chronicle*, MM. Kraus and Kaiser have been making some researches from which it appears that the trunks of trees undergo daily changes in diameter. From early morning till early afternoon there is a regular diminution till the minimum is reached, when the process is reversed and the maximum diameter attained at the time of twilight; then again comes a diminution, to be succeeded by an increase about dawn—an increase more marked than that in the evening. The variations in diameter coincide, therefore, with those of the tension, but they are shown to be inverse to the temperature, the maximum of the one corresponding roughly to the minimum of the other, and so on.

**PHENOMENA OF OPTICS AND OF VISION.**—M. Treve. The author mentions the fact that the flame of a lamp appears brighter, and that a vertical shaft, a post, or mast is seen more distinctly through a vertical than through a horizontal slit, while a house, a landscape or the disk of the sun or moon is perceived more clearly through a horizontal slit. He finds similar differences in photographs according as the light passes from the object to the plate through a vertical or a horizontal slit, and ascribes the results to the action of diffused light.

**A NEW CELLULOID.**—This new product is said to be obtained from well peeled potatoes, which are treated for 36 hours with a solution of 8 parts sulphuric acid in 100 parts of water. The mass is dried between blotting paper, and then pressed. It is further stated that in France smoking pipes are manufactured out of this new material which are quite equal in appearance to the meerschaum. By heavy pressure the material acquires such a hardness that billiard balls can be manufactured with it.

**THE BLUE OF THE SKY.**—M. Chappuis thinks that the blue of the sky may be due to ozone present in the upper regions of the air. He argues that the electrical discharges constantly taking place will produce ozone; and the recent researches of himself and M. Hantefeuille have shown that ozone, at any rate when near its condensation point, is of a blue tint. He has examined the absorption-spectrum of ozone and finds nine dark bands in it, three at least of which correspond with known bands in the telluric spectrum.

**THE TELEPHONE THROUGH WATER.**—*L'Electricite* states that M. Dohrn has introduced the telephone in connection with his scientific explorations of the bed of the Bay of Naples. By its use the diver and the hoaman overhead are able to communicate with each other quickly and intelligibly.

**CONVERTING SOUND INTO LIGHT.**—A French scientist claims that he has succeeded in reversing the result obtained by Prof. Bell, in producing light from sound. He has described an experiment to the French Academy, by which he contends a transformation of sound into light is produced.

**A NEW COMET.**—Mr. Lewis Swift, of Rochester, N. Y., has announced to the Smithsonian Institute, the discovery, by himself, on the morning of May 1st, of a new and quite bright comet. It rises a little before the sun and is moving slowly south.

A NEW FURNACE PRODUCT.—Herr W. Sonnet, of Duesseldorf, proposes a method for utilizing blast furnace cinder. He melts 60 to 80 parts of cinder, 10 to 20 parts of soda residues, 1 to 20 parts of lime, 1 to 10 parts of manganese ore, and 1 to 10 parts of diabase rock in a cupola so as to obtain a material having the following composition: Silica, 60%, lime, 10%; alumina, 10% oxide of iron and oxide of manganese, 8%; and alkalis, 12%. It is stated that this material is so hard and tough that it can be turned like steel. It resists the action of water so well that it can be used for pipes, tubes, masonry, door steps, window sills, etc.

PARK CITY looks way up as the leading mining camp in Utah. More improvements are being made there this season than ever before in the history of the place.

TIN, silver and lead in paying quantities have been discovered near Ilwaco, Oregon.

## MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertisements in Mining and Scientific Press and other S. F. Journals

### ASSESSMENTS—STOCKS ON THE LISTS OF THE BOARDS.

several men are employed at this mill. Placer mining on the Salmon has paid better the past season than for many years. O. O. McVail has made one clean up of \$1,000, and will make another clean up, which will end the season. The Schumacher brothers are taking out about as much a day to three men. Bloomer and Hamilton are making five and six dollars a day to the hand. The season here is slow here during this season, will be a short one, there being no snow in the hills. Mines generally shut down early. At Big Bar, Mr. Silby has taken at 50 ounces, and probably will take out as much more for the season closes. Taking the whole length of the season the reports of a short but very successful season among the placer mines, and of new and rich discoveries of quartz.

## NYO.

**YACACIO ORE.**—Inyo Independent, May 21: Cameron's mines passed southward yesterday, going to Cerro Gordo haul ore from the Yacacio mine to the mill at Keeler. The ore is first class, and will amount to 200 tons or more quantity.

**SWANSEA SLUG.**—From A. W. Elsbeth, who returned from Cerro Gordo to-day, we hear that the Swansea mine, have been overhauling the immense slag pile at the base of the hill, with astonishing results. Thousands of tons of rich, half-smelted ore and metal have been sorted out.

**IRON EXHIBITION.**—Mr. Woodhull's assay of ore from the Jack discovery at Beveridge district, resulted in 61.07 gold, and 7.85 in silver; total \$507.62 per ton. It is one of the new properties, and belongs to Dan O'Connell, Jack Welsh, Nate Mount, Charley Holmback and John Rankle.

**STARK ROCK.**—J. H. Ely, writing from Swansea, relates a discovery of "a world's wonder"—a quartz ledge (thin 200 yards of the edge of Owen's lake, near the Jeweller station. The ore sent is lead sulphides, of a low grade. John's veracity is at stake in the matter and wants the public to come and see the "wonder."

**FOR TASTING ORE.**—As completing the Keeler mill, so far as pecuniary and thorough knowledge of the business is concerned, Supt. Holt has just constructed a 1-stamp mill, and 2 small amalgamating pans. It is distinct on the regular works, and intended for crushing and sizing all varieties of milling ores, in lots of 10 or 100 lbs. more. It is a "prospect mill," destined to prove a very important auxiliary to the main concern.

**MINES BONDED.**—An agreement has been perfected between Wm. Hamilton, of the Kern & Inyo State Co., and the Inyo County, whereby, for the sum of \$1,000, the latter contracts to give a bond for a deed to the Hidalgo, Maria and El Plan gold mines, situated near Juarez camp, in Beveridge district. If, at the end of that time, the purchase price is not paid the \$1,000 is to be forfeited.

**THE LATRA MINE.**—This is a location in Beveridge district by Nate Mount, Jack Welsh, Omla Mairs and A. R. McKillo, and gives promise of considerable value. It is located on the following assays of its ore: Black ore, 3.50 gold, \$318.05; silver, \$4.70—total, \$323.65; honey-bell ore, gold, \$190.75; silver, \$5.40—total, \$196.15; white ore, 3.33; silver, \$1.17—\$20. The assays were made by T. Luther & Co., of Bodie.

**SOLD.**—The Minnata mill property, of Lookout, has been sold by Belshaw & Co. to an Arizona company, represented by J. L. Porter. It is to be removed to a point on Grapevine, on the Mojave river.

## LOS ANGELES.

**OUR MINES.**—Cor. Los Angeles Herald, May 21: We are, in the township of Soledad, have every reason to believe that we are on the eve of some astonishing developments in the way of mines. Within 15 miles on the northeast of Soledad, mines are now being worked by men who have struck pay rock (gold) which yields at a rate of one half ounce to the pan. On the northwest of Soledad, mines at the Union mine are taking out rock which will yield (the best of it) at least \$1 to the ton and in gold. This mine is about seven miles from Soledad, owned by Rush & Herrick. At the Escudilla mine, 14 miles from Soledad, they are striking very rich rock. Fourteen miles northwest of Soledad and 11 miles north of the town of Soledad, there has been a new district organized, bounties established and Recorder elected, called the Minnata district. There have been eight locations, all of which prospecting extraordinarily well on the surface. The present Climax mine has the best prospects. There are now running a tunnel into the ledge and are striking the ore in the wall rock. They will strike the main ledge at 40 ft in by 80 ft down from the surface, and then on the ledge. The district is easy of access, and is in a very healthy locality. By railway, the best way is to get off at Newhall and follow up the wagon road to the ranch, owned by Noah Chiswick, or he is more familiarly known, by the sobriquet of "Old Tex." In a short time you may look out for developments in this district that will open the eyes of Los Angeles people not only, but of people of other counties.

## SONO.

**THE NEAL.**—Inyo Independent, May 21: Developments the famous Neal mine, Indian district, near Benton, are reported as highly favorable, the 21-ft ledge holding its ore to the greatest depth, some 80 ft. Some of the ore says up to \$120 per ton, gold and free milling. It is now a property of Dr. S. A. Middleton.

**THE QUEEN.**—Supt. Adams, of the Indian Queen property, near Benton, says that the mine has sufficient ore in it to assure, for 8 or 10 months to come, the company's gulch dividends of \$17,000 to \$18,000 per month.

## EVADA.

**THE ESPERANCE CLAIM.**—Nevada Transcript, May 19: The Esperance bedrock tunnel, at French Corral, owned by Messrs. Coleman, McLean and others, is now in about 10 ft, but will probably have to be pushed 1,300 ft before reaching the gravel deposit being searched for. A full crew of men are working on it day and night, Sundays included. The Esperance Co. have a small tunnel in the hill of ground situated below the famous Milton mine, and supposedly on the same channel.

**LEADON CLEAN-UP.**—Theodore W. Sterling and his sister yesterday visited the Idaho mine and explored some of its workings. While at the mine they saw the result of week's run melted down, and the amount realized was to gold bars worth about \$14,000.

**ROUND MOUNTAIN MINE.**—The contractors engaged in vacating the main tunnel of the Round Mountain drift vein claim so as to explore the hill, have already gone 1 ft, making it now in 636 ft. They have 250 ft more to go, but as the formation being passed through is soft talus and bedrock, good progress is being made and they will probably complete the contract within the next four months.

**MINE COMPANY'S PROPERTY BURNED.**—Last Saturday afternoon a fire caught in the kitchen of a boarding house at Fall Creek, Washington township, destroying the boardinghouse, blacksmith shop and tool-house, all owned by the Blue Teat M. Co. A defective stovepipe led the damage.

**THE BANER MINE.**—On Sunday the tunnel of the Baner mine while being pushed north to a small ledge of blue ore heavily sulphuretted. Since then the ledge has been widening out rapidly and improving in quality. The place where the strike was made is at a vertical depth of 10 ft below the surface, and will soon be under the place where the very rich red gold croppings were found a few days since. If the ledge in the tunnel continues to hold out a while longer, the machinery will be removed to a point below the heavy ledge, and the water is pumped out. It will be run to the south, so the ledge can be worked from both directions. The hauling of quartz will begin on Monday.

## LACER.

**THE VALLEY FORGE.**—Placer Herald, May 21: We mentioned some weeks ago that J. W. Foulks was putting up machinery on an extension of the famous Bell mine, down at the Valley Forge, with the view of thoroughly developing it. Passing there the other day we noticed his

works in full operation. He is already down on the incline some 70 ft, and from top to bottom has a large ledge which prospects very good—the rock in some instances showing free gold. In sinking he has taken out from 50 to 70 tons, which he intends soon to have crushed, and from which he expects big returns. He is making arrangements for a steam crushing mill, which he will build close to the mine.

## PLUMAS.

**STARK BED ROCK.**—Plumas National, May 21: The shaft of the American Valley Co., in the flat below Loring & Leavitt's claim, found bottom on Wednesday, but evidently struck down on a high spur of smooth washed bedrock, which was piling rapidly to the southeast. The shaft will be sunk 8 or 10 ft deeper to make a snip for the water, and then the drifting will begin. The gravel is several ft in depth on the bedrock, and shows a prospect in fine gold, and from this indications it is probable that pay in the crevices will soon be found. The shaft is 102 ft in depth to bedrock, and is probably in a low place, which makes it favorable for easy work when the drifting begins, as the water will drain to the pump.

**RENNING.**—The mills are running steadily and work in each mine is progressing with its accustomed regularity. There is no wonderful strikes to record, as this is not a sensational mining district. It abounds in low grade ore, and in crushing this our mills are actively engaged.

**PROF. W. F. BLAKE,** of New Haven, Conn., consulting engineer of the Green Mountain, Cherokee and Gold Stripes, arrived on Tuesday, to make his regular visit to the mines, note their progress and advise as to future working.

Important developments in reference to change of ownership, and the resumption of active work in mines in this vicinity now idle, are soon to take place, which will be duly announced. The future of this district is destined to be of great importance in the mining industry of this coast.

## SAN DIEGO.

**IRONWOOD DISTRICT.**—Arizona Mining Journal, May 21: Mr. Jessie Whitten returned a few days since from Ironwood district, 20 miles west of Ehrenburg, on the Colorado river, in San Diego Co., Cal. During the past year there has been a resumption of excitement relative to mineral deposits, in the country lying along the foothills, and mountain skirting, thick desert, and several discoveries of more or less importance have been made in gold, silver and copper, prominent among which is the Copper Chief, Silver Dime and Lucky Strike, embraced in what is known as Ironwood Mining District. The ledge upon which these claims lie, runs through the country for miles, it has been exposed in a number of places and shows a uniform width of about 7 ft, lying between two places of contact. The ore is very rich in gold, silver and copper. The returns in some instances showing \$25 in gold and 20% copper. Others show very rich in silver. Jessie and Dick Whitten and Adolph Schimpf, have bonded 7,500 on this ledge. Much of the ore shows free gold.

## SHASTA.

**FRANK OUTLER.**—Cor. Redding Independent, May 21: Mr. Shafter's mine has blossomed out into a 3-ft ledge, which pays big. Mr. Chassell has made a discovery of paying quartz on the head of East Fork of Clear creek, and there has been a good prospect in quartz found lower down on the same stream, and we may expect a huge find there any day. The West is going to be a big find. Mr. Willey showed us some two ounces of mortar poundings from his lode that needed no quicksilver to save it.

## SIERRA.

**GOOD FIND.**—Mountain Messenger, May 21: Jas. Patterson, who owns a large amount of mining ground on Excelsior hill, has struck it rich. It seems there are two channels, a front and a back channel. He has been working for years in the back channel, making it pay fairly. Recently he took a notion to prospect for the front channel, which had been worked in places in former years, but not followed. As good luck and good sense would have it he found the channel the first day and made an assay. The ore is very rich in gold, silver and copper. The haul is light and the top dirt easy to get rid of, and by the hydraulic process Jim will be able to take out a bushel of money next year. The hearty of the business is that Jim owns all the ground himself, and thinks the channel extends about 3,000 ft. The gold is finely washed, one piece being shown that weighed \$40.

**THE ROCK TUNNEL.**—The rock is very hard and the tunnel is being made with a Burleigh drill. Under the able direction of Supt. H. W. Wallis, work is steadily progressing in a most workmanlike manner.

**HIDDEN TREASURE.**—The shaft on the Hidden Treasure quartz mine is down about 25 ft and the rock prospects as well as at the top.

**EXTENSION.**—The Extension reservoir was completed on Wednesday, but no prospecting has yet been done so far as we can learn. A gateway has been started from the main tunnel and is now off about 30 ft. The bedrock rises on a grade of about 4 ft in 100 so far as they have progressed.

**WIND DAM.**—A company of Chinese are preparing to wind dam the river just above Durgan bridge.

## TRINITY.

**WATER FAILING.**—Trinity Journal, May 21: Miners are still sluicing hereabouts, but water has begun to grow less and may be expected to fail rapidly if the present warm weather continues. It is expected that 2 or 3 weeks more will mark the end of the sluicing season. The generality of claims have succeeded in doing an average year's work.

## TUOLUMNE.

**BUCHANAN.**—Union Democrat: John A. Davis has bought the Buchanan mine and what one proceeded to work it systematically. No machinery is to be used. The mine has lain idle for several years. The trouble with former owners was, that being without means they tried to make the mine pay for its own development. Having passed into hands possessing the necessary capital, there is every reason to believe that very valuable property will be opened. There is no question among miners that it is one of the best in the county.

## NEVADA.

### WASHOE DISTRICT.

**SIERRA NAYAOA.**—Virginia Enterprise, May 22: Preparing to tap a drill hole in the incline, 30 ft below the 1700 level, to run a pump. The machinery is to be used for repairing the north lateral drift. The joint Union Co. and Sierra Nevada winze has been sunk and timbered 13 ft. During the past week 294 tons of ore have been raised.

**CON. VIRGINIA.**—On the 2000 level are hauling water from the Best & Belcher joint winze preparatory to connecting upraise from the 2500 level. On the 2500 level are every other drain and enlarging the east drift from the C. C. shaft.

**CALIFORNIA.**—On the 2000 level the drift north from No. 1 winze from a point 30 ft below the 2000 level has been extended 12 ft. On the 2500 level are cutting out a drain and enlarging the main east drift. Have resumed work in the joint Ghril east winze.

**YELLOW JACKET.**—The water in the mine is to-day 140 ft below the 2500 level, or 90 ft below the foundations of the 2500 pumps. During the past 48 hours we have been draining the 2500 levels of the Belcher and Crown Point mines. The lift pump in the shaft works well, while the donkey pumps have caused much delay and loss of time in lowering.

**NEW WELLS-FARGO.**—Work was resumed on the New Wells-Fargo mine on the 9th inst. After a thorough examination of the machinery it became very evident, from the neglected and rusty condition of the engine, that repairs and alterations would be necessary before active operations could be resumed in the mine. Since that time engineers have been employed in overhauling the

machinery and boilers. This work is now about completed. The first work in order will be a thorough examination and further development of the vein cut in the shaft at a depth of about 75 ft from the surface.

**ALTA.**—Easting timbers and putting in a set of pumps at the 1800 level.

**UNION SHAFT.**—The shaft has been sunk and timbered 9 ft. The 2700 station set is in place, and are casing timber between the 2300 and 2400 stations.

**UNION CO.**—On the 2500 level the joint Mexican winze has been sunk and timbered 13 ft, and the joint Sierra Nevada winze sunk and timbered 13 ft.

**UTAH.**—Since last report the incline has been sunk and timbered 12 ft. The south drift on the 2150 level has been extended 13 ft. The ground in the face of the drift is somewhat harder.

**MEXICAN.**—On the 2500 level the joint Union Company winze has been sunk and timbered 12 ft, and the joint Ghril east winze has been sunk and timbered 13 ft.

**OPHIR.**—On the 2500 level work in the joint California winze has been resumed, and the joint Mexican east winze has been timbered 13 ft.

**HALE & NORCROSS.**—The west crosscut on the 2400 level reached the west wall in 217 ft. Nothing of value was found. Preparations are being made to sink a 3-compartment winze 30 ft north of the 2400 station. The 2100 level is finished and our pump running. The best in the mine is intense.

## ESMERALDA DISTRICT.

**WHAT IS DOING.**—Esmeralda Herald, May 21: While there is no startling development during the week, work has been going on the same as usual, and there appears to be a much better feeling among the miners. On account of the prospect of having a good mill erected, and perhaps two of them, at an early date. The Superintendent of the McIntosh & Barnes received word from his company that they have decided to send him a 10-stamp mill, with all modern improvements, and have contracted for the delivery of the same. It is now a settled fact that the Cortez Co. will commence the building of a mill with at least 10 stamps in a short time. The Esmeralda will be placed on the list with the bullion-producing districts.

Following is a brief statement of the work done at the different mines for the past week: The Cortez has been working day and night. The incline shaft is now down nearly 100 ft, in good ore all the way. The Centennial is opening up well. Work was commenced at the bottom of the incline shaft this week, which shows a steady improvement all the time. The slopes on the upper level are turning out the usual amount of rich ore. The Festoons, located north of the Cortez, is one of a group of mines owned by Ellis Drake. The vein has been stripped a distance of 300 ft and shows good ore the entire distance. The Humboldt West is looking more favorable every day. The crosscut from the bottom of the 100 shaft is now in about 26 ft. The entire ledge shows \$25 to \$30 ore. The Prospects, we understand, is looking much better, and a decided improvement is expected in the drift in a few feet. A shaft is now being sunk in the New Esmeralda through the cap rock at the southwest end of the property to catch the ledge. No work has been done in the tunnel since working the 12 tons of ore, the result of which fully satisfied the owners that they had a good mine.

## EUREKA DISTRICT.

**THE GEDDES & BERTRAND.**—Sutcliffe, May 21: Mr. Clark, Superintendent of the Geddes & Bertrand mine, was in town last night. He has got matters in pretty good shape to prosecute the work of development. Among other things, a new pump reaching down to the 350 level has been put in. There is a fine body of ore on the 75 level. A drift has been started on the 150 station, to cut the ore found above. The drift is now in 40 ft and is looking promising. It is expected to tap the ore within a distance of 30 ft more. As soon as the mine shall have been developed, reduction works will be constructed to treat the ore on the ground. Mr. Clark is an excellent miner and manager, and we have no doubt that there is a bright future ahead for the Geddes & Bertrand.

## LEWIS DISTRICT.

**MILLS RUNNING.**—Silver State, May 21: George Berger, who has been on a business trip to Lewis, informs us that there are two mills—one of 15 and the other of 10 stamps—running steadily in the district. Some 50 men are at work on the 40-stamp mill. Henry Vogt is putting up a brick kiln of 150,000, and when that is finished he intends to build another one. Barney Rice is painting and Doc Alder is running a restaurant. There are three hotels, three stores, two restaurants and five saloons in the place. Several new buildings are going up, and the middle town is being removed to the lower town. The Star & Grove employ 50 men; the Highland Chief, 45; the Betty O'Neal about as many more, and in the whole district some 300 men are at work. Everybody seems to be at work, and the town has a very lively appearance.

## ARIZONA.

**MINERAL CREEK MINES.**—Pinal Drill, May 18: D. B. Spangler, from Mineral Creek camp, near the Gila river, was here this week buying burros, camp supplies, and hiring men to work. This gentleman is a member of the Pinal Copper Co., whose works are in Pinal county, organized under the laws of California, having their office in San Francisco. The company commenced operations about four months ago by securing in quite a number of valuable copper mines, among which are the Monroe, Ray, Esperanza, National, Tibbets, Ida Bell, Green Mountain and Reed. There are several others all having more or less work done on them. The Reed alone has produced 150 tons of ore at a cost of \$2,000 for development, and the Monroe shows a vein of about 4 ft of very fine copper ore, while the average assays from these mines show 25% copper. The new smelter is of 30 tons capacity, and was started up last Wednesday. It has a water jacket, and is similar to the Copper Queen, of Tombstone district. There are 500 tons of ore at the smelter taken from the different mines. These reduction works are about 13 miles from Pinal. The mines are about 13 miles. The route is by the Bauman mine. Eight miles of road has been built by the company, six of which are towards Pinal, reaching Walnut Grove. Fifty miles of road are now being built, there have been 80. There are increasing their forces.

**PROSPECT DISTRICT.**—The Gem mine is yielding good ore. The mill is running and proves satisfactory, and regular work will now go on. This property belongs to the Wide Awake M. Co. They have expended \$40,000 to \$50,000 for work, and have paid for everything as they went along, and have money in the treasury for what they want. The Silver King mine is working over 100 men. On other mines in the immediate vicinity over 500 more miners are employed. A large number of men are awaiting the completion of the hoisting works at the Eastland, Bilk and Nowry, for employment. The usual miners' wages, \$4 per day, is paid. There are 3 teams with 16 mules to each, hauling 60 tons of Silver King ore to the mill daily. They are hauling concentrating ore to the mill, as to keep the stamps going, as the road have a quantity of pulp on hand for lixivating. While at Silver King we visited the Eastland M. Co.'s works, overlooking the village. A new office building, convenient to the mouth of the shaft, is completed, and also a temporary carpenter and blacksmith shop. About 40,000 ft of lumber is on the ground for shafting and building purposes. The hoisting machine is being put in place, and the engine, 40-horse power, 600 ft of inch cable. Steam power to sink the shaft 1,000 ft, all will be in full operation in about 10 days.

## IDAHO.

**THE MOTTER LODE.**—Yankee Fork Herald, May 21: The more the Charles Dickens mine is developed the more we see that the great bonanza of the future is here. As the shaft on the summit progresses in depth the mine yields richer ore, and the indications now are, as the rich pay dips toward the east, that the great body of ore is not the one now being developed. A crosscut is being made in the lower tunnel near the face through the foot wall, and is now in very rich stringers, indicating that there is another body of ore south of the ledge, where pay had not been looked for.

Three more men were put to work in the Montana mine during the week. The ore in the lower works is way up, and a good deal of it will be stopped out by the blue pack trains can get to the mine.

**PROSPECTING.**—The snow off sufficiently to admit of prospecting in the high mountains, and now is the time for prospectors to come to the Yankee Fork country. Mines of great value have been found in the past, and there are many more yet to be discovered. But men coming to prospect should bring a few dollars with them, as they may not find mines that will yield well by hand mortar process, as did the Charles Dickens and Montana.

**PLACER.**—Nevada Press, May 15: There is a ripple of excitement on Camas prairie relative to extensive placers discovered last fall on Little Snake creek, 7 miles west from Florence; the ground prospects all the way from 10 to 50 cents to the pan on the bedrock, with color running from the tops of the ridges to the creek bed. The new diggings will be thoroughly prospected this summer.

## MONTANA.

**CLOSTER MINE.**—Cor. Helena Independent, May 21: A better prospect for a thrifty mining camp than the Kloster now presents, is rarely seen. This mine is the property of the Gregory M. Co. A 10-stamp mill has been employed continuously for more than a year in cleaning up the ore from the drifts alone, and although a pump has not yet been stopped, two handsome dividends have already been declared, thus proving an exception to the general rule that a loss is sustained until stopping begins. A 40-stamp mill will soon be put up just below the one now in use. Any one who enters this mine will be impressed with the neatness and security of its timbering. Up to the present time this camp has been isolated, so to speak, owing to the fact that during a part of the year it was almost inaccessible by way of the road from Belmont. Hitherto the only road to it. But the company have about finished a good road to the camp. The new road runs from Silver City by way of the Trinity road along the foothills till it strikes the Little Prickly Pear, thence up Piegian gulch, and around the foothills, approaching the mine from the west.

## NEW MEXICO.

**NEW PLACERS.**—Cor. New Mexican, May 19: The miners at Golden are taking life as they find it, and while the United States is disposing of the land, the miners are developing their own resources. John McKay and Thos. Munns are now engaged in making fire brick, and will soon begin the erection of a smelter for the purpose of working their own ore. J. M. Lucas has started up his arasters. His ore is very hard, and his efforts are an experiment, which the value of the ore alone can determine.

**BLACK RANGER.**—The Olust mine has a pay streak of mineral that will carry in assay samples \$40,000 per ton in gold and silver. It is telluride ore, incased in a large ledge of quartz, and is being worked by one shift of men.

**POVERTY AND BEAR CREEK** have large ledges of quartz carrying high grade ore, but as yet not thoroughly examined. Prospectors are developing.

**TURKEY CREEK** has a post office called Oraeton. Here there are some fine bodies of ore which are well developed, namely:

**THE WASHINGTON**, which has a 70-ft tunnel and 50-ft shaft; there is a large lot of ore on the dump. The Montezuma, a 40-ft shaft, working one shift, has 25 tons of ore on the dump, which mills about \$100 per ton. The Alaska, Yankee Boy and Paster are looking finely and working one shift each. South from Turkey creek, and next in order, are the El Paso and Dreadnought mines, which are excellent properties, being worked with a good force of men.

## OREGON.

**NOTES.**—Democratic Times, May 20: B. W. Huston, of Foot's creek, was in town Wednesday and showed us some neat nuggets of gold taken out of his claim, one of which weighed \$15 and another \$3. He informed us that some of the miners have cleaned up for the season, while others are following suit.

**WILLOW SPRINGS.**—We learn that the ore of the Roton ledge, in Willow Springs district, is not as rich as formerly, though still of a good quality. The company evidently struck a pocket, which seems to be worked out.

**FOORMAN'S CREEK.**—Keaton & Klippel, of Foorman's creek, have cleaned up with satisfactory results. Among other gold taken out recently, were three good-sized nuggets, the smallest weighing \$13 and the largest \$25.

**PUMP.**—Cunningham & Barkdell will put in a pump on the quartz ledge in Blackwell district, as there is considerable water in the shaft—so much so that it interferes with the prospecting. The ore is of a decomposed character, and quite a sum has been expended by means of a hand-mortal.

**MINERS** are winding up the season's work everywhere. The run was over a month short. Chappell & Co., of Star gulch, cleaned up their boxes the other day, with good results. P. T. Ives is on his regular prospecting tour in the Sierrita mountains. John Richards and other parties are likewise engaged there. Frank Towne, of Sterling, informs us that the miners of that section are all cleaning up, as water is falling fast. John Beckner and Jas. Burns have finished cleaning up their work on Mission Flat, with fair success. They talk of emigrating before long. Kleinhammer, Towne & Reynolds, of Sterling, are cleaning up and doing well. They brought 106 oz. of dust to town a few weeks since. Savage Bros., of Rogue river, have about two-thirds of their ditch completed and will soon suspend operations, as the ground is becoming very dry and hard. Sheriff Bybee returned from Waldo this week, have consummated a contract with the Chinese to construct several miles of ditch for the firm he is a member of. Bybee & Fisher are working on the harden of their ditch leading to Big Bar and expect to complete the enterprise in about two weeks. They will then have a fine water privilege. Glen Lin cleaned up some boxes the other day. How much gold-dust he got none but the Mongolian himself knows; but those doing business with him say it was considerable.

**POCAHONTAS ITEMS.**—From a gentleman residing near Pocahontas we learn that the mining season in that district is an extremely productive one, and the prospect for an abundance of water is good. Jack Low & Co., on Ruene gulch are doing well. Nelson & Co., on Salmon creek, have 2 large giants at work. Akers & Co., on Mill creek, have 1 large giant running all the time. Hayes & Co. are working steadily, with good results, on their quartz ledge. Baisley has 3 giants at work, one of them is the largest in the county.

## UTAH.

**SILVER BELT.**—Silver Reef Miner, May 21: A contract has been let to Messrs. Watson & Co. to sink 40 feet on the lower level of the Silver Belt. The completion of this will no doubt go far towards determining the value of properties in that promised land.

**SILVER REEF ITEMS.**—Miner, May 21: Fifty-one men, all told, are employed about the Stormont mines. Henry Thomas, an amalgamator, at the Christy mill, was killed last week by being caught in a belt and carried around the line shaft.

**HIGH SPOKE.**—The work of straightening up and driving the crosscut on 3 still continues, 40 ft of high grade ore having been gone through already. A 218 oz. assay was made from the face of the crosscut and some ore found being the almost unprecedented assay of 50% lead and 200 ozs. silver. The company shipped 11 carloads of their own and 3 cars of the Frisco Co. to the Rio Grande.

**ARTICLES OF INCORPORATION.**—Articles of incorporation have been filed in the office of the Secretary of State in New York for the purpose of purchasing and working the Cerro Oord, Minnesota, and five other mining locations at Frisco, Utah Ter. These mining properties, now negotiating, cover the notable Cerro Gordo silver hill, near the celebrated Horn Silver mine in southern Utah, and are chiefly owned by R. F. Derickson and E. E. Wood, of Chicago, Ill.

## THE MINE-JUMPING SEASON OPENS UP BRISKLY IN THE BLACK HILLS.

### What the Tourist May See.

The visitor who now turns his eyes upon the California landscape sees the height of its loveliness. It is true that in some parts the yellow of summer ripeness is stealing in upon this scene, but taking the State as a whole it is in its loveliest dress. Fortunate are those who now look upon it. It is the peerless time when earth and air and sky play their sweetest parts, until house walls become prisons and roofs a burden. It is the time when California goes out of doors.

Visitors will be warned, no doubt, that the many hues of flower-flecked fields, which now entrance their vision, will fade away, and that the landscape will come beneath the reign of dust and desolation. To a degree this is true, though not to the extent it once was. The increase of orchard, vineyard and timber areas, the spread of forage plants constantly green by irrigation are doing much to break the old monotony of summer browns and yellows.

While strangers are prone to bewail the short-lived green of our landscapes, they should not forget that it is from the death of our natural verdure that comes the life and prosperity of the greater portion of our people. The drouth which covers the midsummer traveler with dust is the secret of the successful harvesting of our immense grain crops. With an Eastern summer, grain growing on the scale now practiced would be impossible. And if the earlier drouth is thus salutary, the continuance of it is not less so, for it gives the fruit grower his opportunity. Cloudless skies from September to November are the secret of full success in our vineyards. Without them the ten-ton yields of wine grapes would be partly sacrificed, and our vigorous raisin industry would be impossible. Therefore, mourn not the death of the green, as one mourner without hope; for as we have said, it is the key to the prosperity of a number of our agricultural industries.

It is to be expected that many who come for a sojourn in California do not seek alone the beauties of the landscape, but desire as well an acquaintance with our cultures. Those who come from Eastern agricultural districts will perhaps be pleased to see the specialties which engage their attention at home. Therefore, perhaps a running directory of the regions where each may be found, will be of avail to some of our new readers. Of course, to accurately direct attention to all localities where certain industries have taken root would exceed our space. We can but point to the localities where most of a thing may be sought.

Our greatest wheat fields may be seen in the San Joaquin and Sacramento valleys and in Monterey, Ventura and Los Angeles counties; barley in immensity in Los Angeles county, and in quality of Chevalier in the lower part of Alameda county. Corn fields, which the country cannot surpass, are in Los Angeles county; rye in Stanislaus; flax in San Mateo, San Luis Obispo and San Benito; oats in San Mateo, Humboldt, Mendocino and Siskiyou. The greatest amounts of hay are cut in Santa Clara, Sutter, Contra Costa, Tehama and Butte counties. The great pea region is in Humboldt, and beans in Santa Barbara and San Luis Obispo counties. Castor beans reign in Los Angeles county. Potatoes are most abundant in San Mateo, Sonoma, San Joaquin and Alameda counties; sweet potatoes in Sutter, Los Angeles and Yolo counties; onions in Alameda, Los Angeles, San Mateo and San Joaquin counties. Hops are largest in Mendocino, Los Angeles, Santa Cruz and Napa counties; tobacco in Los Angeles, and cotton in Merced and Kern counties. Sugar beets are grown in greatest quantity at Alvarado, in Alameda county.

To find interesting illustrations of California dairying one can hardly go amiss if he hunt from the coast line to the high valleys of the Sierras. The greatest hutter counties are Marin, Sonoma and San Luis Obispo, and in cheese San Luis Obispo, Sonoma and San Benito lead, with Marin, Santa Clara and San Mateo following. The greatest alfalfa fields may be seen in Tulare county, along the Sacramento river and in Los Angeles county. Los Angeles leads in wool with nearly 3,000,000 lbs., Mendocino and Tehama have half as much and Merced, Fresno, San Luis Obispo and Sonoma counties yield over 1,000,000 each. Honey flows most freely in Los Angeles, San Diego and Ventura counties.

Even to catalogue the fruit regions would require a column. The earliest tree fruits are to be sought in Solano county, and strawberries may be found the year round in sheltered spots from Santa Cruz southward, near the coast, to the State line. In similar localities the tomato becomes perennial and the potato is unvisited of frost. The greatest wine regions are Sonoma and Napa counties in the north; Yolo, Santa Clara, Sacramento, San Joaquin and Alameda in the center; El Dorado, Tuolumne and Placer in the Sierra foothills, and Los Angeles and San Bernardino in the south, with luscious beginnings in Fresno, Calaveras, Contra Costa and elsewhere. The largest raisin vineyards are in Yolo, Sutter, Fresno and San Bernardino, and gnatwart beginnings here and there over the fogless valleys and the genial foothills. Without attempting to specify the hosts of the standard fruits, it may be said that the masses of temperate zone fruits come from Sonoma, Napa and Solano, from the Sacramento Valley region and the foothills, the district around Stockton, and from the beautiful valley west of the Contra

Costa hills, including Alameda and Santa Clara counties, with extensions toward the south and to the coast at Santa Cruz and San Mateo counties. This enumeration is geographical and takes a swing around, with San Francisco as a market center. Beyond this, from north to south, many so-called northern fruits are growing to greater or less degrees of perfection, according to local conditions which prevail. The most that can be said of them in a sentence, is that many fruits are reaching the fullest excellences where it was thought they would not grow at all, and some fail where the best results were expected.

The semi-tropical fruits must be sought in profusion in Los Angeles and San Bernardino counties, with gratifying results already attained in Santa Barbara, Ventura and San Diego counties. Very fine orange and lemon trees in smaller numbers may be found in favorable locations in nearly all the fruit regions of the State.

The great lumber regions of the State lie in two lines along the coast and upon the sides of the Sierra Nevada. Both are of much interest both in methods and materials. See the redwoods in Humboldt, Mendocino and Sonoma counties on the north, and in San Mateo and Santa Cruz on the south. The Coast range is their home. On the Sierra foothills and mountains look for mills working spruce, pine and fir, in Tehama, Nevada, Placer, Butte, El Dorado and Sierra counties.

THE product of the Storey county mines for the quarter ending March 31st, according to the returns to the Assessor, was 21,002 tons, valued at \$426,353, or an average of \$21 per ton, against 49,100 tons, at \$1,615,800, an average of \$33, in the corresponding quarter of 1880. The detailed statement for the last quarter is as follows: Belcher, 1,989 tons at \$33.953; Crown Point, 4,696 tons at \$68.301; California, 3,150 tons at \$63.780; Con. Virginia, 4,818 tons at \$111.506; Con. Imperial, 2,931 tons at \$38.104; Ophir, 217 tons at \$5.174; Savage, 47 tons at \$1.682; Sierra Nevada, 2,286 tons at \$97.463; Monte Christo, 820 tons at \$7.380.

In the suit of the Empires Gold Mining Co. against the Pacific Gold Mining Co., the necessary affidavit and the undertaking on attachment having been filed, Chief Justice Morrison R. Waite, of the Supreme Court of the United States, on the 12th inst. ordered that an attachment issue in the case. The U. S. Marshal made his return on the writ, showing that he had attached the Oaks quartz mine, 1,200x500 feet, on the lode of and adjoining the Empire claim, at Plymouth, Amador county, known as the Pacific Gold Mining Co.'s mine. The action is to recover \$120,000, and the bonds required cover this amount and damages that might result from the attachment.

We see by the *Pioche Record* that during the past eight days a large number of people have left that part of the country, most of them being old timers. Bristol lost nearly half of its inhabitants the other day, all departing in one solid band, feeling gay and happy. This party were destined for the Wood River country. A host of the Piochers have departed for other fields and pastures new. Most of them have gone to Wood River and Montana, while others will search for employment as near Pioche as they possibly can.

BULLIONVILLE SMELTER.—The furnace closed down a week ago and the water-jackets are now being placed in position. The short period that the small furnace has been running the company shipped fourteen car-loads of bullion, which Mr. Frank Godhe stated, was valued at fully \$30,000. The experimenting with the new mill process is still going on, and it is thought that everything in regard to the machinery will be in readiness to start up at an early day.—*Pioche Record*.

ACCORDING to the *Virginia Chronicle*, D. R. Fraser, writing from St. Elmo, Col., says that Comstock miners are scarce and in demand. All that a man has to do is to say that he is a Nevada miner and he gets work immediately. Mr. Fraser remarks, however, that it won't do to lie about it, for there are good miners here from all parts. The wages are from \$2.25 to \$3 per day and board for miners. The tenderfoot get \$40 per month.

THE machinery at the New Wells Fargo mine is found to be in a shameful condition. The parties who last run it seemed to have stopped the engine and walked away and left it without putting a drop of oil into or on any part of it. In consequence it is a mass of rust.

AL. FRENCH writes from Tombstone, Arizona, that the camp is booming, but it is no place for men in search of employment, as there are too many idle men in the place now. One miner can extract as much ore in the mines as four men could in California or Nevada.

THE *Inyo Independent* says that the State Line mine appears to be developing far better than the most sanguine hoped for. Five shafts are being sunk, and all exhibit any quantity of ore, some of it assaying as high as \$10,000 to \$13,000 per ton.

THE Giant Gap company, Iowa Hill, Placer county, have spent \$13,000 in running their tunnel, without having yet reached gravel. But the indications are considered sufficiently encouraging to warrant a continuance of the work.

### Nevada County Mining Camps.

Mining camp is a name applied to towns located in mining regions, or mining districts. It matters not how large a town may be, if it is dependent on the mines in its immediate neighborhood for support. This name originated in 1849-50, and was then applied to all towns located in the mining regions. We use the word "camp" now, in accordance with the meaning as then given to it. Of these camps there are in this, Bridgeport township, eight (not including Montezuma Hill), to wit: French Corral, Empire Flat, Birchville, Sweetland, Sebastopol, North San Juan, Cherokee and Badger Hill.

At French Corral the great Milton mine is located—one of the best mines now worked in this township by hydraulic process. The town contains less than 100 inhabitants, though the school district contains, perhaps, 200 people. In the town proper there is a post-office, water office, a hotel, one saloon and an elegant school-house.

At Empire Flat, a half mile this side of French Corral, there is a store, which supplies nearly all the residents of the Corral with groceries and provisions. It is known as the French Corral store, and is owned by M. Darneal & Bro. It is at Empire Flat George D. McLean and others are running a tunnel to open up their mining ground, which is known to be very rich.

At Birchville, three miles from French Corral, in this direction, there is a large tract of mining ground owned by the Milton Co., which is not now being worked. Birchville contains one grocery and provision store, Geo. B. Newell's, and one very excellent schoolhouse. There was formerly a hotel and a saloon at that place, but at the death of the proprietors, they were both closed up. The building formerly occupied as a saloon, was purchased by Peter Graham, and removed to Sweetland. The town of Birchville proper contains a population of less than 50 people, while the school district contains 100 people or more.

Sweetland is a good sized mining town, situated a little over two miles from this town, on the Marysville road, having in close proximity the Manzanita mine and the famous Buckeye mine. It is a town of considerable importance, and boasts of having two hotels, two grocery and provision stores, one saloon, and one of the finest constructed schoolhouses in the county. The Manzanita mine, close to the town, is one among the best hydraulic mines in the State. Sweetland proper contains a population, including the miners, of about 200 people—men, women and children. It is an old town, the oldest perhaps in the township, except the Corral. It holds its own remarkably well.

Sebastopol is located about one mile from this place, and about half way distant between this place and Sweetland. It contains about 20 families. The celebrated American mine is near this town, and nearly all the male residents of the town find employment at that mine. Sebastopol has no hotel, no saloon, or store of any kind. It has, however, an elegant schoolhouse, at which some 30 or 40 children are receiving an education. The Sebastopol people receive their supplies of groceries, etc., at this place and at Sweetland.

North San Juan, the next town in order, contains a population of about 800 souls, perhaps 1,000 in the school district. It can boast of two hotels, three grocery and provision stores, two dry goods stores, one drug, book and miscellaneous store, two clothing stores, two furniture stores, one bakery, one hewery, four saloons, three tobacco and candy stores, one wagon-making shop, one undertaker, three blacksmith shops, one livery stable, one cabinet-maker, one upholster, four physicians, two attorneys-at-law, one dentist, one lumber yard, five carpenters, one wash-house (Chinese), four dress-makers, one tailor, one horse manufactory, one ladies' furnishing store, one printing office, two fire hose companies, one telephone office, express office, postoffice, one watch maker, one barber shop, telegraph office, and two very fine schoolhouses. Also, one church, and one shoe and hoot making establishment, Thomas Harris, proprietor. The only mine at work on San Juan Hill proper is Bowen & Rings.

Cherokee is a mining camp situated about four miles up the ridge. It, too, is an old town, and at one time was a place of considerable importance. There are no mines of any magnitude being worked in the immediate neighborhood of Cherokee, though the town is located on rich mining ground, and is surrounded by ground that will pay for washing. At Cherokee there are two hotels, one grocery store, one blacksmith shop, one shoe manufactory and a very fine schoolhouse. The population of Cherokee proper will number probably 100 souls. The school district, about as many more.

Badger Hill is a mining camp about two and a half miles from Cherokee, and numbers about 50 people, including men engaged in the English mine, which is located at that place. There are no stores there of any kind, nor saloons. It is, literally speaking, a mining camp, occupied by family residences scattered over a large extent of country. The only mine worked there at present is the English mine. Though the Milton Co. own a large tract of mining ground adjoining the English Co.'s claim.—*San Juan Times*.

SNYDER concentrators are used at Rough and Ready, Nevada county, and elsewhere for saving sulphurets, also for black sand.

### Wood River.

A great deal is being said about Wood River, for and against. Those persons who want to get work there had better read the following article carefully. We take it from the first number of the *Wood River News*, and it is evidently a very true statement of the situation:

As this issue of the *News* will have a very large circulation, we feel it a duty we owe our fellow workmen to state the exact situation of affairs for their class of people on Wood River at the present time, and the prospects of the future. Only a few strong, rich companies have any hold in this country as yet.

The properties they do own show large deposits of rich galena, and a few men can take out enormous quantities. The number of prospectors who have opened claims along the river is vast, but they (the prospectors and owners) are poor. They have no means to pay help with, and the ore they take out has to be shipped, at least, so far as Salt Lake City, and then return, though they will lempy pay, in most cases cannot be expected to always prove satisfactory to the demands of all manner of actual expenses.

In spite of all the *News* can say, we know there will be a great rush to Wood River this spring of the class of people who barely have sufficient means to land them in Bellevue. Only a small proportion of these men will get work at remunerative wages, and they will be of the experienced hands at mining. It is well to think of this before grabbing up your gunny sack full of threadbare clothing, old letters and faded photographs, to seek employment at big wages of a poor people in an unexplored though evidently rich mineral region 150 miles from the railroad ties.

As a matter of justice to the *News* when five months later, perhaps, you are "hoofing it" for the railroad—it may be on scant rations—cussing your luck and the country, please let your memory run back to the time when you perused these lines, and remember that you called us a "bear." As anxious as we are to handle coin, we do not wish to get it by inserting advertisements of "Situations Wanted." When we are called upon to say, "5,000 good miners wanted immediately!" our readers can rest assured that Wood River is booming, and we will welcome the honest laborer heartily, and assure him of getting first-class wages.

It is the opinion of many experienced mining men, who have at different periods visited this region, that for all classes of laborers this will, in time, be a good country, but until there are smelters, mills, and facilities for condensing Nature's crude richness in this vast mineral belt, those who expect to be dependent upon capital for daily labor, had better linger in more congenial climes, and where "spuds and hamfat" are cheaper.

AMERICAN VS. ENGLISH MACHINERY.—A practical miller, writing to the *Glasgow Herald*, expatiates at great length upon the causes which have brought about the ruinous competition of American millers with those of the British Islands. He contends that the English millers have neglected the most important point in this contest for the supremacy—viz., the improvement of their machinery, and that, therefore, the only reason why the American producer can import and undersell his English competitor is that he has the means through his superior mechanical appliances to produce a finer grade of flour at a cost and with an ease which puts the English miller hopelessly in the background. The writer, however, claims that much of the American flour imported into England is sold at an actual loss, and advises his co-workers to adopt the most improved American machinery now in use, and seize upon every new device as it comes from the inventors' hands.

MATTERS AT THE MINT.—The *Carson Appeal* says: "From the way supplies are being taken in at the Mint it does not look as if the institution was to be closed. Yesterday, 22 tons of copper ingots were received from the Ludwig copper mines, while 30 tons are lying at the Mound house, waiting transportation. There are now 2,500 tons of ore lying in the dump of the Ludwig, which will produce 250 tons of pure copper."

THE Director of the Mint estimates the total amount of gold in circulation in the United States (including bullion in the Treasury) at the commencement of last week, to be \$520,000,000, of which about \$264,000,000 was held as Treasury and National Bank reserves, and \$256,000,000 was in actual circulation. There has been a total gain of gold coin and bullion to this country, since July 1, 1879, of \$234,000,000.

SINCE August the Dunkin mine at Leadville has been turning out from \$21,000 to \$33,700 per month, while the expenses for the same time have averaged only \$6,500 per month. The ore now worked nets from \$22 to \$35 per ton, and there is said to be a considerable quantity of ore in sight. The mine is paying monthly dividends with regularity, and has already disbursed \$185,000.

MEADOW VALLEY CO.—The mill of this company at Dry Valley has been running for about six weeks, and during that time Superintendent Duff has paid out to the chloriders and for supplies and labor to the company, \$30,000.

## THE ENGINEER.

## Immense Steamships.

A company has been organized to build a class of express steamers of immense size to run between New York and Milford Haven. Report says the steamers will be 550 ft. long, 45 ft. beam, and that they will draw about 25 ft. when loaded; but these figures must be taken as approximate; as well as the statement that they will carry 5,000 tons of goods and 400 first-class passengers. It is estimated that their speed will be about 23 miles an hour.

No such speed has ever been attained by any screw steamer of large size; and it has only been reached by a very few paddlewheel yachts on rare occasions. The first ship driven at this speed across the Atlantic, will have performed a feat without, for a time, a parallel; and when we hear in mind what a rapid ratio the resistance of a ship increases with each augmentation of speed, it will be seen that the construction of the proposed express Atlantic steamers presents a tremendous problem for solution to naval architects and engineers.

Calculations have been made, which appear to be accurate, and they go to show that engines of 16,000 indicated horse-power, and probably more, will be required to drive a ship of the stated dimensions at 23 miles an hour across the Atlantic. It is very doubtful if the required velocity could be got at all with a vessel with much less than 7,000 or 8,000 tons displacement. Making every allowance for the skill of modern smiths it is considered very doubtful if a trustworthy shaft of the dimensions necessary for such a screw could be made. The *Engineer* says: "Allowing that steel is to be used, and that the shaft will be built upon the most approved principles, we shall find that many portions of it cannot be less than two ft. six inches in diameter by about seven ft. long. Sound forgings of these dimensions have never yet been produced. The weight of such a block would be, when finished, nearly eight tons. It is true that heavier forgings have been made for years, but they have not been solid. We do not assert that a sound crank shaft, with minimum diameter at any place of two ft. six inches, cannot be made; but we do say that no such shaft has yet been made, and that it will not be easy to produce one. Such a shaft might, perhaps, be depended upon to transmit power safely at the rate of 250 horses indicated per revolution per minute. This means 64 turns per minute to provide for 16,000 horse-power, and this velocity implies a great deal more than appears at first sight."

The *Engineer* considers the experiment a very doubtful one, and suggests that their engines and propellers should be of 8,000 horse power each.

LIVERPOOL ENGINEERING SOCIETY.—At the late meeting of this society, a paper on the "Application of Natural Forces to the Production of Motive Power," by Mr. G. C. Thompson, was read, in which the author treated his subject in a general manner, without going extensively into detail, dwelling for a considerable period on the possibility of much mechanical knowledge possessed by the ancients being lost at the present day, citing as a proof, the ruins of Baalbec, where some of the stones employed in construction, according to the author's calculation, must have weighed 840 tons, and required the united strength of 25,000 men to lift into position. Having pointed out some obvious disadvantages in the use of steam and its substitutes, the paper suggested the use of compressed air, to be obtained by automatically utilising the rise and fall of the tide, according to a detailed description and diagram, the main feature of which was the enclosure of 20 acres of coast land, and the formation of a large airtight space, to be acted on by the tide, which, on rising, would pass through the inlet pipe, and force the compressed air through an outlet pipe at the upper and opposite side, when it would become a prime motor. The second portion treated of the utilisation of the wind by means of windmills and pumps for effecting a similar purpose. A discussion followed.

JAMES RUSSEL LOWELL'S TRIBUTE TO THE MODERN ENGINEER.—At the late annual banquet of the Institution of Civil Engineers, the American Minister, in proposing prosperity to the Institution of Civil Engineers, said: "I feel that there are certain relations between engineers and that general civilization of which literature and art can also claim their share, which gives me, perhaps, some claim to propose the toast assigned to me. Naturally, in some respects I confess I am wanting in sympathy with some of the achievements of modern science; yet, with all the world, I must confess that you are the makers and the masters of the modern world, so far as it is visible, palpable, and serviceable to the rest of the world. \* \* \* I think there is no achievement of modern science which so touches the imagination as that narrow bridge for thought which engineering skill has stretched through the profound and silent stretches of the Atlantic between this continent and the other. Nothing touches the imagination more than the way in which the modern engineer has realized that dream of the ancient philosopher—that the earth was a sentient being. It has made mankind contemporaries in a sense in which they were never contemporaries before."

## USEFUL INFORMATION.

## Luminous Paints.

According to the *London Building News*, luminous paint is getting into quite extensive use in England. Mention is made of offices coated with the paint, which give great satisfaction to the occupants. The effect is that of a subdued light, every object in the room being clearly visible, so that in a room so treated one could enter without a light, and find any desired article. The luminous paint is excited by the ordinary daylight, and its effect is said to continue for about 13 hours, so that it is well adapted for painting bed-room ceilings, passages that are dark at night, and other places where lamps are objectionable or considered necessary. For staircases and passages a mere band of the paint will serve as a guide, and costs but a trifle. For out-door purposes the oil paint is used, but for ceilings and walls the luminous paint, mixed with water and special size, can be used the same as ordinary whitewash, and presents a similar appearance in the daylight. By the recent discovery that it can be applied as ordinary whitewash considerably expands the field of its usefulness. Sheets of glass coated with the paint are in use in some of the vessels of the navy, at the Waltham Powder factory, at Young's paraffine works, and in the spirit vaults of several London docks; and now that, by increased production and the use of water as the medium, its cost is reduced by one-half; it will probably be extensively used for painting walls and ceilings. The ordinary form of oil paint has already been applied in many ways—to statues and busts, to toys, to clock faces, to name-plates, and numbers on the doors, and notice boards, such as, "mind the step," "to let," etc. The paint emits light without combustion, and therefore does not vitiate the atmosphere. Several experimental carriages are now running on different railways, the paint being used instead of lamps, which are necessary all day on account of the line passing through occasional tunnels.

COPYING DRAWINGS.—By a method patented by M. Joltrain of Paris, it is claimed that copies of drawings having nearly black strokes on a white ground can be made by the following sensitising mixture: Gum, 25 grammes; chloride of sodium, 3 grammes; perchloride of iron at 55° B., 10 cubic centimeters; sulphate of peroxide of iron, 5 grammes; tartaric acid, 4 grammes; water to fill up to 100 cubic centimeters. The developing bath may be a solution of ferrocyanide of potassium, red or yellow, acid or alkaline. The printing is done in the ordinary way, and the developing in a bath of red or yellow prussiate of potash. After washing the proof is put into an acidulated bath, which darkens the lines to an indigo tint, and is then again washed and dried.

PAPYROTYPE.—THE LATEST DECORATIVE NOVELTY.—Under this name the *London Building and Engineering Times* describes the latest novelty in products for decorative treatment of interiors. Papyrotype is neither paper or tile, but a tough, pliant fabric, in substance like leather, though artificially composed of prepared materials which result in a non-conductor of heat and sound. These quasi-tiles may be advantageously employed for wall or ceiling decorations simply by the aid of glue or other cement, and are readily cleaned by the ordinary dust brush. The decoration is applied in one or more colors to straight or curved lines, either flat or in high relief.

ASHES AS A SUBSTITUTE FOR EMERY.—We copied a paragraph on this subject a week or two since. And now comes a correspondent in the *Iron Age* who writes as follows: "A paragraph has been going the rounds of the papers that some one has discovered in anthracite coal ashes a substitute for emery. As it may save many from going to the trouble of washing ashes to try this last discovery, I thought I would write you to say that as the ashes in question contain only finely divided silica, which can be bought crushed, graded and bottled to any degree of fineness for one cent per pound, \$20 per ton, it does not look as though it was worth the trouble and bother of extracting it from refuse of any kind."

MOUNTAIN mahogany is a wood indigenous to this coast. The trees do not grow large; one with a trunk a foot in diameter is much above the average. When dry the wood is about as hard as hoxwood, and of a very fine grain. It is of a rich red color and very heavy. When well seasoned it would be a fine material for the wood carver. In the early days it was used in making boxes for shafting, and in a few instances for shoes and dies in a quartz battery. Used as a fuel it creates intense heat, it burns with a blaze as long as ordinary wood last, and is then found (almost unchanged in form) converted to a charcoal that lasts about twice as long as that of ordinary wood.

LUBRICATING GEARS.—Where a mill is driven by mortise gearing it has been recommended to use a mixture of pulverized chalk and linseed oil for lubricating purposes. It is said that this mixture is much better for wooden cogs than oil, tallow or flour. The chalk for this mixture should first be pulverized and then sifted with a fine sieve.

## Painting on Brown Paper.

Painting on brown paper is now all the rage. Concerning the new craze the *London Queen* says: "Brown paper of the darkest shade and thickest texture, and gray paper of a coal granite tint are just now in demand as materials for painting upon for dados, panels, cornices, and book-covers and other things. They give a background on which the light and shade are at once relieved; and while gray paper is the softest, brown paper, partly by the contrast of the rough surface, gives the most relief. The best brown paper for the purpose, is the stout, continuous kind used by the paperhangers and upholsterers for hacking, which can be had at all the carpet warehouses in any quantity. The colors are oil paints in tubes or water colors, well ground with Chinese white, used with fine bristles or red sable brushes.

Another method is to lay on the Chinese white, well ground to the consistence of thin cream, and when it is dry to paint over it with ordinary water colors. Red sable brushes are also the best for both the latter. Minute finish is out of character with the kind of work; the effects should be put in broadly, and the designs be distinct and of few large objects. In connection with this subject it may be appropriately mentioned that the "Angry Swans," two of the finest of Turner's drawings, which are on exhibition at the National gallery in London, are painted on common brown paper, which had been used as the wrapper of a parcel.

A PULVERULENT LUBRICATING MATERIAL for axles, shafts, etc., is prepared by Herr Drechsler, of Dresden, thus: The finest graphite powder is worked up thoroughly with egg-white, or yellow, or both, to a firm dough, which, in a metallic vessel, is kept in a vessel of boiling water till the egg-white and yellow are fully coagulated. The mass is then dried at 90° C., so thoroughly that it can be bruised or stamped to powder. This powder is applied to a slowly-revolving axle or shaft till axle and bush take the peculiar dark shine of graphite.

HIGH UP.—The crown of the hat of the statue of William Penn, which is to surmount the tower of the new public building of Philadelphia, will be just 525 ft. above the pavement. This is ten ft. and one inch bigger than the highest towers of the Cologne cathedral.

TO MAKE MODELING CLAY.—Knead dry clay with glycerine instead of water, and a mass is obtained which continues moist and plastic for a length of time. This removes one of the greatest inconveniences that is experienced by the modeler.

## GOOD HEALTH.

USE OF THE EYES.—The man who avoids excesses of every description has a fair chance of retaining his eyesight until old age sets in. A time comes to every one when the physical powers begin to decay, and then, unless the brain has been kept active and recipient by exercise, there is nothing left to live, and the man perishes. We say that he died of gout, or over-eating, or of kidney disease, or of the failure of the particular organ which was the first to exhibit symptoms of the approaching end. In reality he has died of stupidity, artificially produced by neglect of the talents with which he was endowed. That which is true of the organism as a whole is true, also, of its parts; and the eyes, among others, are best treated by an amount of systematic use which preserves the tone of their muscles and the regularity of their blood supply. Acuteness of sight is aided by the attention bestowed upon objects within the range of vision. In people who cannot read the sight is far from acute. I have even had reason to think that the wives of such men were indebted to their household needle-work for the maintenance of a higher standard of vision than that of their husbands; and I have no doubt that idleness of the eyes, if I may use such an expression, is in every way hurtful to them, and that proper and varied employment is eminently conducive to their preservation and efficiency.

SALICYLIC ACID.—Experience has shown that salicylic acid should be employed with care for internal use. It is soluble in only a very limited number of ordinary solvents; hence it is liable to crystallize in the stomach under certain conditions, from which serious consequences may arise. It should be taken internally only under the advice of a physician. It is considered so dangerous in France that the French Minister of Commerce has issued a circular to the prefects instructing them to forbid the sale of any article of food, solid or liquid, containing salicylic acid, or any compound of it. The attention of the sanitary authorities has been called to the danger to public health by the use made of this substance for the preservation of food, and M. Tirard has had a thorough analysis of its properties made by the Consultation Committee of Hygiene. The result of the committee's examination is that the acid is injurious to health, not only on account of its direct effects on the system, but also indirectly, by permitting the fraudulent introduction into food of other "deleterious, or at least unwholesome, substances."

THE BRAIN WORKER.—So long, says a medical authority, as the brain worker is able to sleep well, eat well, and take a fair proportion of out-door exercise, it is not necessary to impose any special limits on the actual number of hours he devotes to his labors. But when what is generally known as worry stops into complicated matters, when cares connected with family arrangements, or with those numerous personal details which we can seldom escape, intervene; or when the daily occupation of life is in itself a fertile source of anxiety, then we find one or the other of these three safeguards broken down. Probably the man of business or the successful lawyer fails to shake himself free from his anxieties at night, and slumber becomes fitful or disturbed. The nervous system, unsettled by the mental strain, brings about various defects in nutrition, and then we meet that depression which is the chief misery of the overworked.

THE ENERGY OF THE HEART.—We may form some conception of the enormous energy of the human heart when we reflect that a good climber can only ascend 9,000 ft. in nine hours, that is, can only raise his own weight 1,000 ft. in an hour, that is, of course, continuously for any length of time, while the work done by the heart is equivalent to raising its own weight (10 ozs.) 13,860 ft. high; and we may put this even more strikingly by pointing out that the most powerful engine ever made by men, the "Bavaria" locomotive of the Vienna and Trieste railway, can only raise itself through 2,700 ft. in an hour; that is, its energy is less than one-fifth of that of the human heart (Houghton). Of course, the actual amount of work done, both by engine and climber, is much greater than that done by the heart; but relative to weight, the energy of the heart far exceeds that of the other two.

LACK OF AIR.—Some workmen think themselves "tired," when they are only poisoned. They labor in factories, breathe air without oxygen, and in an atmosphere of death. They are, too often, allowed to smoke, and thus add fuel to the flame that is consuming them. They knock off work "tired" and listless, when they are merely weakened by foul air and made dull and heavy by an atmosphere charged with disease. They keep the windows shut and close the door on health, while they lift the gratings of the tomb by breathing and re-breathing the poison from their own lungs, and the floating particles of matter about them. Open the windows—let in the sunshine and the breeze, stop smoking, and you will soon find that it is the poison of confinement, and not labor, that wears and tires.—*Montreal Herald and Star*.

ALCOHOLISM A PREDISPOSING CAUSE OF CRIME AND EPILEPSY.—In a recent number of the journal with the awkward title *Brain*, Dr. Clarke has published some tables of statistics, which lead him to the conclusion that "alcoholism of parents is a predisposing cause of crime and epilepsy in their children." Forty-four per cent. of the epileptic criminals were the children of drunken parents. The proportion of epileptic and insane relatives is found to be very much greater with criminals than with ordinary epileptics. The convictions for hasty are three times as numerous among epileptics as among non-epileptics. The statistics show that the amount of crime, as indicated by the number of convictions, is greater among epileptics than among ordinary criminals.

CURE FOR WARTS.—A correspondent of the *Scientific American* writes as follows: Some years since a corn doctor advised me to use coal oil. My hands were covered with them. Having little faith I tried it, putting a drop on each of common kerosene and letting it absorb; where there was a hard crust, scraping it to facilitate absorption. In a fortnight after twice daily treating them, they began to lessen, and finally disappeared without scar. Then the right hand, in part, leaving one which remained after all others had passed away, and then that one. Have advised others to try it, with like effect on persistent use. Simply softened the top, dropped the oil on, and let it be for some minutes to absorb.

PITTING OF SMALLPOX.—Dr. Swimmer advises a mask to be formed of very pliable linen cloth, leaving apertures for the eyes, nose and mouth. The inside of this is to be smeared with one of the following liniments. 1. Carbolic acid, 4 to 10; olive oil, 40; and prepared chalk, 60 parts. 2. Carbolic acid, 5; olive and pure starch, of each 40 parts. 3. Thymol, 2; linseed oil, 40; and chalk in powder, 60 parts. The mask should be renewed every 12 hours. Compresses impregnated with one of these mixtures may also be placed on the hands, and on any parts of the face with which the mask does not come into exact contact.—*Gazette des Hôpitaux*.

THE BEEF JUICE FUROR.—In the present furor for fluid beef juice, says Dr. Fothergill, the necessity for starchy matters is being quite overlooked, or to be very safe, underestimated. These meat products furnish—the best of them—little glycogen or animal starch, and yet that is the fuel food of the body *par excellence*. We must be guided by rational knowledge, by physiology and not by fashion, in our dietetics. When there is very feeble digestion, then the digested milk and milk gruel advocated by Dr. Roberts is to be employed.—*The Practitioner*.

Annual Meeting—Gover M. & M. Co.  
Carson and Colorado Railroad.  
New Revision of the New Testament.  
Pattern Letters—H. W. Knight, Seneca Falls, N. Y.

## Passing Events.

The principal news of the week, from a miner's point of view, is that the big hydraulic pump on the Comstock broke down, and it will take two months to repair it. This is a serious accident, and one much to be deplored at the present time.

The news from Alaskan mines, which we give in another column, is not especially encouraging for those who have gone up there. But it may be taken as a general proposition that all reports from newly discovered regions are more or less exaggerated. Those persons who have had experience always accept such rumors with a "grain of salt."

The news of the cave in the Black Hills mines was received with regret, but the disaster was not so bad as was at first reported. Ground was broken this week on the Black Hills and Custer City railroad. The road will run from Deadwood to Custer, with a branch to Rapid City. The total distance is about 70 miles. It is being built by the Homestake M. Co., principally to furnish timber and fuel for their mines and mill.

From Wood River come somewhat contradictory reports, as was to be expected. It is said, however, to be a good "poor man's country." That is, the metal is near the surface and easily mined. It is, however, like any new camp, a poor place for men to go, who are without means and dependent for their support on daily labor.

The season now being fully opened, prospecting operations are going on in all directions. Arizona and New Mexico both attract numerous miners and prospectors, owing to the fact that large extents of new territory are here open. We may expect to hear from this on reports of new districts being formed, new strikes, etc.

## Wood River.

The recent reports from this new mining district are of a very contradictory nature. When the earliest news came of the discoveries made last fall in the Wood River country, the facts were undoubtedly highly colored, as is apt to be the case with all new mining regions; and latterly we hear accounts carrying quite as decided a bias toward the other extreme. The truth, as usual, lies between the two. Many, who had been carried away by the enthusiasm aroused by the earlier reports, have this spring flocked from the older mining camps in every part of the country to Wood River, and inaugurated a "rush" which promises to rival those of Reese River and White Pine. They found, on reaching their destination, that all the more promising "prospects" had been located by the first comers; that work was scarce, as compared with the number seeking employment; that the expenses of living were high and accommodation limited. So, of the throng which has been pouring into the Wood River country since the opening of the season, not a few have returned to their former camps in a disgusted frame of mind, and inclined to think and say that the new mines are a humbug. A number of papers published in the mining towns have obtained their information from this source, and have spread it widely; without, however, checking the rush. In spite of all discouragement, it is safe to say, that not less than 10,000 men will have been attracted to Wood River during the coming summer and fall.

We will briefly state the leading points of interest to those who may still have in mind a pilgrimage to this latest strike. The Wood River country embraces a tract of about 45 to 50 miles in length by 25 in width, lying on both sides of the stream from which it takes the name, and about the head waters of numerous feeders to the main river. It is in the center of Alturas county, Idaho, and nearly in the center of the Territory. Immediately south of the Wood River country are the great Snake River lava beds, which extend through Idaho and neighboring Territories for some 800 miles. The river runs from north to south, emptying into the Snake. On the north and west of the district are the Sawtooth mountains, in which several good camps had been struck previous to the Wood River excitement. The country composing the district, or rather series of districts, is of very varied character. About Bellevue, the most easterly and principal town, the valley is broad and quite flat, the mountains forming the sides of the valley converging toward the north, but split up by innumerable gulches. At the head of this valley the country becomes more rugged, and at Galena and to the north is exceedingly grand and picturesque. The altitude varies from 5,500 ft. above the sea level on the prairie land to 9,500 ft. at the northern portion of the district, some of the mines, as the Eunice and Gladiator, being situated at an altitude of 10,000 ft. above the sea level.

The climate is not so severe as is generally supposed, and is certainly not to be compared in point of cold with that of Yankee Fork or Cariboo. At Bellevue, where the greater number of last year's miners and prospectors wintered, the weather may be considered mild in comparison with that of many mining camps, the altitude being lower than most silver districts. The average fall of snow at this point may be placed at three feet for the season. Communication was maintained regularly throughout the past winter. What is known as the open season begins about April 1st and continues till December. During the early spring, however, the roads are heavy and transportation difficult. The summer is very pleasant.

Wood River is reached through two main routes. One, the more frequently taken by those having their own teams or saddle animals, is by way of Kelton, Utah, on the C. P. R. R. The other is the stage route from Blackfoot, on the Utah Northern R. R., a branch of the U. P. R. R., connecting with the latter at Ogden, Utah. The distance from Blackfoot or Kelton is nearly the same, but the former route is the easier one. Freight is brought in from either point at about the same rate, which was 2½¢ to 4¢ last season, including carriage over the Utah Northern R. R. from Ogden to Blackfoot. The fare from San Francisco to Kelton is \$30 emigrant—time, three days; first-class, \$53—time, two days. From Kelton to Bellevue it is 150 miles by stage; through in 36 hours; fare, \$25. Through freights from San Francisco to this place range from 1.65¢ to 4½¢ per lb.

Wood and water are abundant. In the lower portion of the Wood River country there is little timber but cottonwood, but further north are forests of fir, spruce and pine, furnishing excellent mining timber.

Bellevue is undoubtedly destined to remain the principal town, being the natural outlet of the country; and it has grown with mushroom rapidity. Further north are the towns of Hailey, Ketchum and Galena, which are nearer the mines; while a number of smaller camps are springing up at intervals throughout the tract described.

The ores of the district are argentiferous galena—a large proportion of which is the steeley variety containing antimony; carbonate of lead associated with bromide and iodide, and occasionally anglesite. The galena shows but traces of gold as a rule, but carries from 60 to 350 ozs.

of silver per ton. The shipments to the Salt Lake smelting works last year averaged 125 ounces per ton; and, in fact, almost all the galena in the country carries sufficient silver to pay for shipment. The assays of the carbonate ores are very variable, running from traces merely up to very high figures; and the value of the ore cannot be readily determined by the eye, reliance being placed on close assaying. The country rock embraces a wide range of varieties, limestone and shale being the most common, while porphyries of several types and granite are also found as the habitat of the lead deposits. The veins, as with all lead districts, are irregular and generally narrow, but widen in places to extensive chimneys, such as those of the already famous Bullion, Idahoan and Scribner mines.

It is expected that two custom smelting works will be in operation this year. This will be a great advantage, especially to owners of small mines.

Quite an important system of business operations has already sprung up. Freight and stage lines, the furnishing of mining supplies, etc., are naturally leading branches. The opportunities for establishing these, we think, have been pretty well exhausted by the more enterprising first-comers. Still, as the district has undoubtedly a life of at least three years before it, judging from what has been already uncovered, there may still be room for further business ventures.

At present, the largest mine-owning interest of the district is centered in Salt Lake City. Eastern buyers are, however, coming in, while several of our San Francisco mining men have had an eye on the Wood River country for some time, and have had their experts in the field, picking up promising claims.

In conclusion, we would strongly urge upon all who may think of going to Wood River to make ere before starting that when they have arrived they will have means of subsistence for many months. The history of these mining "rushes" has been a painful one, but ever repeat itself. We hope that in this case there will be fewer disappointments, less privations. There will be work for skilled miners, smelters, carpenters and blacksmiths, but little for the common laborer. While wages are high, the expenses are still higher, certainly offsetting the increased earnings. If the country fills up as rapidly as the indications show, there will, we fear, be an over-crowding, just as has happened at Tombstone and other new camps, and many will find it harder to find employment in Wood River than at their own homes. We trust this advice will be heeded.

## Zone or Lode.

When the case of the Eureka-Richmond mines was brought before the U. S. Supreme Court, Mr. Thos. Wren, in his argument for the Richmond Con. said: "The Court (below) finds that this entire zone is a lode; and the whole case rests, in my judgment, upon that question. But if that zone is a lode in the meaning in which those terms are used in the Acts of Congress, then the case, perhaps, should be affirmed. But if that zone is not a lode in the sense in which those terms are used in the Acts of Congress, then there is nothing found outside of that upon which this judgment can rest."

The decision of the Supreme Court does not definitely answer Mr. Wren's question, but it says: "Whether the limestone was or not, within the meaning of the Acts of Congress, and the understanding of the miners, a single vein, lode or ledge, it was all mineralized or metal-bearing rock as distinguished from the barren walls in which it was inclosed. It descended into the earth on an angle, and unless parties in working it could follow its course as it went down, they could not avail themselves to the full extent of the wealth it contained. When, therefore, we find parties contending about their rights to its possession, and finally agreeing on a line of division between themselves which shall be continued downward toward the center of the earth, the conclusion is irresistible that the line was to be extended downward through the property in its course toward the center of the earth."

Prof. R. W. Raymond (who was one of the experts), commenting on this clause in the decision, says: In other words, whether this zone answers the set definition of a lode or not, it is bounded like a lode, it dips into earth like a lode, it must be followed in working like a lode, and boundaries drawn across it, to settle titles and end disputes, must be extended just like boundaries drawn across a lode. We do not wonder that the august tribunal adds: "This disposes of the case."

In avoiding to give an unnecessary definition of a lode, which might be used as a basis of verbal quibbling in some future case, the intention of the court appears to have been to leave all other contests to be decided, as this has been, on their merits.

**GOLD MOUNTAIN.**—Paul Frisk, in the Grantsville Bonanza, speaks favorably of the outlook at Gold Mountain. Of course things are a little dull at present, but when water is brought in there will undoubtedly be a boom that will cause a genuine excitement. A good deal of money is expended on dead work, and it will take time to open the mines and get the mill in running order. When everything is fixed, then look out for brilliant shipments.

## Holding Ground with Prospect Holes.

Not in one mining camp, but in many, is there a strong feeling against the habit of men coming along and digging a dozen or two holes which are nothing but holes, but never more, and which keep other men off of unprospected ground. This thing is usually done by a lot of greedy fellows who sink holes and hold claims, half the time with no signs of mineral, but who hope to sell to others, or to hold ground which others will make valuable. There have been numbers of instances where this has injured the district. In fact, it retards development in every camp. We notice the statement of a correspondent at Baldwin's camp, New Mexico, which he says is being slowly developed. He says:

"It was first opened by some tenderfoot who put down a great many holes where there was not the least sign of mineral. These stupid efforts had the effect to stop the development for a time. Miners of experience are now at work there, and two or three genuine leads have been recently opened which bid fair to prove that the fine formation of these mountains really means something."

In Colorado, they are having a great deal of trouble with the practice. At Argentine district a lot of miners finding "slide-rock" holes all over the district and noticing no work was being done on them, went to see the tenderfoot locators, telling them to work the holes or they would. A few days passed and no work being done, the men jumped the claims. Shooting ensued, and one man was killed and a number wounded. Mr. Joseph Bush, a pioneer prospector of the district, explains, in the *Leadville Democrat*, the cause of the difficulty, as follows:

The tenderfoot, he says, makes his advent in a district and sinks a multiplicity of holes in "slide" rock and then asserts and holds it as a valid claim. If a tenderfoot hole, he added, was on, or in a true fissure vein and mineral in place, it would certainly be all right in the eyes of the law; but on the other hand the true prospector and experienced miner is bound to denounce the 60 and 90 day regulation in reference to assessment and recording. "For instance," said he, "a man goes into a district the middle of June and makes a hundred locations, claiming 90 or 60 days for developments. He is a tenderfoot and has an idea that these holes can be disposed of for mines. He permits them to lay undeveloped. The experienced miner comes into the country, who would work them, but he sees the evidence of location and passes on."

"Finally the claim is forfeited by the tenderfoot, and the miner is cheated out of a year's work, and the development of the district retarded and seriously injured. If a conscientious prospector locates a claim, he settles down and works diligently upon it, but the emigrant of to-day displays an aversion that is fearful to behold. The legitimate prospector that has worked for years, made fortunes and lost them, concentrates his efforts within a fair territory, and, not wanting a whole mountain, will confine himself to one place, thereby giving others a chance to 'try their luck with a pick.'"

This matter is causing much dissatisfaction among the prospectors. As it is now, there is a resolution among the miners, initiating steps toward an abolition of the 90-day policy.

## Copper.

The business of copper mining is now rapidly reviving on this coast. The discovery and development of extensive copper mines in Arizona, has turned attention to many neglected properties in this State, being known, but never worked to a profit. It has been proven that ore could be worked here as well as abroad, and there are now several furnaces running in Arizona and making money. We expect to see, within the next few years, a very general reviving of this extensive interest. There are hundreds of good copper mines in California, which, if provided with suitable metallurgical appliances, would pay well. Cement copper in this city is now worth 15½ cents for 100 fine.

In England the price of copper has declined of late. On the 30th ult. quotations for good ordinary brands were £58 15s. to £59 per ton; ore, 12s.; and regulus, 12s. 3d. per unit. Chile exports to April 26th equal 15,148 tons fine. Stocks of west coast produce were equal to 32,060 tons fine against 32,301 tons on the first of the month. The quantity of Chile copper about as advised by mail and cable to the 22d of April, is 13,246 tons, against 10,890 tons on April 1st. Stocks of other than Chile produce are 15,981 tons fine.

The following are the Board of Trade returns of imports and exports for the first three months of the following years, (estimated) in fine copper:

IMPORTS.	1879.	1880.	1881.
Ores.....	2,649	8,842	1,946

### The Buckland Buggy.

We give an engraving on this page which illustrates George G. Buckland's buggy gear, patented through the MINING AND SCIENTIFIC PRESS Patent Agency March 15, 1881. The gear, as the illustration shows, is exceedingly simple and elegant, and its durability and style of finish is such as to recommend it to all who use it. The small views on the upper corners of the cut show the form of clip for fastening the spring to axles.

There are no working joints in any part of the gear, and therefore nothing to ever wear or rattle, making it completely anti-rattling, something hitherto apparently unattainable. The axles being attached to the springs can easily give when the wheels strike any uneven ground and can, therefore, lessen the shock to horse and driver; the wheels thus giving a little have their durability increased. They spring down square, without any side or tilting motion.

This gear can be made entirely of iron and steel, so it is perfectly durable. The springs run from one axle to the other. Therefore they are long springs and ride very easy, and can stand very hard usage. Having no complicated forgings or castings, anyone can repair them.

These buggies have been found well adapted to rough and rocky streets. There being no working joints on this gear, it is apparent at once that it springs down square as a level. A person may stand outside of the body on one step, and yet be unable to tilt it sidewise.

The inventor, Mr. Geo. G. Buckland, of Tulare City, California, has had many years experience as a carriage-builder, and knew where the weak points of buggies existed. He has therefore done away with weak points in this gear. The king bolt is screwed up into the head block and has a jam nut on top, which keeps it from ever working loose, and can easily be tightened up if it wears.

The middle cross frame brace is all in one piece. One great beauty about this simple gear is that it will answer for either buggy or huckboard. Hence a person can change a huckboard into a handsome buggy in a few minutes by adjusting only four bolts. Said bolts can have tail nuts, and would need no wrench or hammer to change huckboard to buggy, which is an item of special worth to all residents of the county.

This is a feature entirely new in carriage building, this susceptibility of change from huckboard to buggy and vice versa. It has never been done, except with this patent gear. It has been found by experience that the form of spring shown is best, for the simple reason that the springs run in the direction of the strain, and do not receive the sudden or dead shock that comes to solid-coupled wagons or buggies. In the form of gear described the wheels give from any shock or jar, and do not strike a stone or other rough ground, hence the ease to the spring and to the person riding.

In these buggies the body may be set either high or low; it may be set in between the springs or on top of the springs, or above the springs as shown in the cut; the springs may be set as close together as desired, by using a short headblock. They are clipped solid in every respect, and can never get out of square or spring down unevenly. The springs may be made in any shape; they can be made straight or be bent up or bent down for phaetons and low wagons or buggies, or be made any desired length, or any width of steel be used in the manufacture of the springs. A wood or iron headblock may be used. The axles may be made either with wooden stocks or the plain iron axles.

**ATTEMPT TO COMPROMISE.**—It was because the Richmond Con. crossed the compromise line and worked the renowned Potts chamber, that the Eureka-Richmond suit was inaugurated. The Eureka Con. claims to have been damaged \$2,000,000 by the working of the Potts chamber. A suit to recover this sum is still pending in the U. S. Circuit Court at Carson. It was not prosecuted for the reason that the main case had been appealed to the U. S. Supreme Court. A suit for damages would not be just the thing until the Eureka had established its right beyond all question to the controverted premises. The late decision removes the question entirely beyond doubt, and it is now in order to proceed with the action and recover damages. The Eureka *Sentinel* says that both companies express a willingness to settle at a fair figure. The Richmond is entitled in equity to a credit equal to the cost of mining, transportation and smelting. This would reduce the damage to the net yield of the ore. The companies were a mile apart when they began to talk figures. But the question has not yet been dropped. A sort of high joint commission is to wrestle with the matter in San Francisco.

The Zacaten mill, Skull flat, near West Point, Calaveras county, was burned last week. Loss, about \$8,000. The fire was supposed to be the work of an incendiary.

### Alaska Mines.

It seems that affairs at the Alaska mines are not as smooth as might be. The placer mines do not seem to amount to much and the quartz is not so rich as was represented. The following items of news were telegraphed from Port Townsend, W. T., when the *California* arrived there from Sitka, Alaska:

In view of the raised influx of miners at Rockwell, Alaska, and the liability of disputes concerning property which might lead to personal collision among citizens, resulting in loss of life, in the absence of civil laws in the Territory, Commander Glass, in command of the naval forces in Alaska, and senior United States officer, has announced officially that in case of necessity, he will use the force under his command to preserve peace, if controversy shall arise involving the right to property which cannot be amicably settled and personal violence is threatened. Commander Glass will hold possession of the property in the name of the United States until its rightful ownership is settled by the proper Federal authorities. He closes his official notice by stating that the operation of any mining regulations not in conflict with United States laws, will in no way be interfered with, and his order is not in any way intended to affect the rights to any property now held or that may be acquired in accordance with such laws. He declares that military authority will be the only recognized government until contrary instructions are received from the President of the United States. Lieut. Rockwell, with a force of 21 mariners and seamen and four officers, are now in quarters at Harrisburg with instructions

### Manganese Ores.

The commercially valuable ores of manganese are the oxides, of which there are six known, the commonest and best known form being black oxide of manganese, which is really the sesquioxide, or the mineral pyrolusite, powdered up. Manganese compounds have valuable uses in dyeing and in medicine. Metallic manganese has not come into use as a metal or as an alloy, though it forms alloys with very promising qualities. The reason for this is the cost of procuring it from the ores.

Pyrolusite is found on Red Rock, in San Francisco bay, just opposite San Quentin, and on the route to the rivers at the head of the bay. It is also found at Brandon, Vermont; at Conway, Mass.; Winchester, N. H.; Salesbury and Kent, Conn. It is also found in Nova Scotia, Moravia, Thuringia, Bohemia, and elsewhere. Mangasite, which is another important form of manganese, we do not find in this State.

The ores which are found as oxides are from a reddish brown to black, varying from earthy to a dull resinous appearance, lacking metallic luster, bruising and streaking either the same or a lighter color. To the eye it more or less resembles some flinty compounds, tin ore, the friable garnet and spinel, some iron ores and certain magaesian rocks. J. S. Phillips, in his "Explorers', Miners' and Metallurgists' Companion," says that manganese is readily distinguished from the flint, tin stone, garnet and spinel by its inferior hardness (not scratching glass), and from all minerals, by affording a surprisingly delicate characteristic greenish hue, when fused with carbonates of soda, either on platinum foil over a spirit lamp, or platinum

### Cleavage of Minerals.

Webster defines "cleavage," with reference to crystallography, as "the quality of splitting or dividing naturally; direction of dividing planes." This definition, with reference to geology, is "division into laminae like slate, with the lamination not parallel to the planes of deposition. Miners in examining minerals often notice that they break in regular lines, but they may not know that there are various forms of cleavage. All or most crystallized minerals have certain directions in which their cohesive power is weakest—ones in which they consequently yield most readily to an exterior force. This tendency to break in the direction of certain planes is what is called cleavage, and it is one of the characteristics of certain minerals. Cleavage differs according to the ease with which it is obtained and according to its direction, crystallographically determined.

Dana says, 1st: Cleavage is called *perfect* or *imperfect* when it is obtained with great ease, affording smooth, lustrous surfaces, as in mica, topaz and calcite. Inferior degrees of cleavage are spoken of as distinct, indistinct, or imperfect, interrupted, in traces, difficult. These terms are sufficiently intelligible without further explanation. It may be noticed that the cleavage of a species is sometimes better developed in some of its varieties than in others.

2d. Cleavage is also named according to the direction, crystallographically defined, which it takes in a species. When parallel to the basal section, it is called basal, as in topaz; parallel to the prism, as in amphibole, it is called prismatic; also macrodiagonal, orthodiagonal, etc., when parallel to the several diagonal sections; parallel to the faces of the cube, octahedron, dodecahedron, or rhombohedron, it is called cubic, as galenite; octahedral, as fluorite; dodecahedral, as sphalerite; rhombohedral, as calcite.

Intimately connected with the cleavage of crystallized minerals are the divisional planes investigated by Reuch. He has found that by pressure, or by a sudden blow, divisional planes are in many cases produced, which are analogous to the cleavage planes. The first he calls *Gleitflächen*, or planes on which a sliding of the molecules upon each other takes place. Thus, for example, if two opposite dodecahedral edges of a cubic cleavage mass of rock salt, all regularly filed away, and the mass then subjected to a pressure in this direction, a *Gleitfläche* is obtained, parallel to the dodecahedral face. The figures on each hand, obtained by a blow on a rounded steel point, placed perpendicularly to the natural or cleavage face of a crystal, are called by him fracture figures (*Schlagfiguren*). The divisional planes in this case appear as cracks diverging from the point where the blow has been made.

In regard to cleavage two principles may be stated. 1st. "In any species, the direction in which the cleavage takes place is always parallel to some plane, which either actually occurs in the crystals or may exist there in accordance with general laws." 2d. Cleavage is uniform as to ease, parallel to all like planes.

### Low-Grade Ores.

The problem, "can low-grade ores be made to pay," is the most important one of any to our mining population. Inasmuch as nearly every camp has more or less of an abundance of low-grade ores, while there are few, comparatively, high-grade ore mines, the method of working low-grade is much more important than the other. In California, we are rapidly solving this question with respect to the gold ores, as will be seen from the following extract from the semi-annual report of the English company owning and working the Sierra Buttes and Plumas Eureka, in Sierra and Plumas counties.

During the last half of 1880 the Sierra Buttes mine yielded 24,864 tons at an average cost of \$3.56 per ton, the mill crushing 25,091 tons at an average cost of 63 cents per ton, making the total cost \$4.19, as compared with \$3.97 in the first half of the year. Despite this slight increase in the cost of manipulation the rock, the aggregated expenses were only \$88,478, against \$101,539. The yield of free gold was \$5.91, and including tailings, \$6.34, an increase of about \$1 per ton. The net credit balance was \$18,024 13s 10d, from which a dividend of 10 per share, or \$6.125, was declared, leaving a balance of \$11,899 13s 10d to be carried forward. The product of the Plumas Eureka mine for the same time was 24,960 tons, and by the Seventy-six mine 12,490 tons, at an average cost of \$2.66 per ton. The quantity crushed by the two mills was 38,571 tons at an average cost of 56 cents per ton, making the total cost \$3.22 per ton. It is this economical working of mines that is attended with such success. The average value of the ore crushed was \$6.50 per ton, the aggregate amount being \$250,482. The profit for the half year was \$21,422 5s 9d from which a dividend of 3s per share, or \$21,093 15s was declared, leaving a balance of \$12,886 11s 3d to be carried forward.

Ore shipments to Salt Lake are being made by the Wood River mines.

THE BUCKLAND BUGGY.

to make no interference, save in the prevention of violence or bloodshed.

Miners and experts say that Harrisburg is the most peaceable camp they have ever seen.

There is yet much snow at the mines, though a good number of the ledges are exposed, and are opening up finely. The mines are good and the ore of a high grade, but not as rich as at first represented. A number of experts and capitalists have been driven off by the exorbitant prices put upon the mines, and the unsettled condition of rightful ownership. Two or three sales have taken place. New discoveries have been made in the same district some eight miles distant. They are not reported on very favorably. The placer claims are not considered of much value, and little or no prospecting has been done upon them. Mining business is already very much complicated, and in the absence of any civil law valuable property may lie idle for a long time. There have been several disputes regarding town lots, but they have all been peaceably settled.

**MINING TROUBLE IN SAN BERNARDINO.**—An associated press dispatch of the 22d says: United States Deputy Collector E. F. Bean seized the Ivanpah Consolidated mill and mining company's mill and other property, under a United States warrant for distraint, on the night of the 17th, at Ivanpah. The seizure was resisted by John McFarlane, J. B. Cook, and others, and an attempt was made by McFarlane and Cook to kill Bean, and also Mr. Hison, who had been deputized and placed in charge of the mine by Collector Bean. J. B. Cook drew a revolver on Hison, and was in the act of discharging it, when Bean seized the revolver with one hand and struck Cook with the other, and then clinched, and a desperate encounter took place between them, during which John McFarlane rushed in with a shotgun and attempted to shoot Bean. Fred. Hison then stepped in, when John McFarlane turned upon Hison and discharged his gun. Hison threw the gun up and the charge passed near his head and lodged in the woodwork of the mill. Then they clinched, and McFarlane, using a knife, inflicted a severe wound in Hison's head, after which Hison drew and discharged his revolver under his arm three times, two shots taking effect and killing McFarlane instantly. Bean and Hison left the mill, and two shots were fired at them by parties concealed in the mill. Mr. Bean succeeded in keeping possession.

or iron wire loop before the oxidizing flame; or in an iron spoon over a clear, open fire. This is by far the best reaction, which may, however, be further corroborated by fusing it with borax in the same manner; when the hot glass will shine from violet to amethyst, and the cold glass reddish violet, approaching to purple, which appears almost black when in excessive quantity.

An addition of a very small crystal of niter increases the color, by more complete oxidation, where minute quantities are present; and pulverization of the bead exposes the thus modified and true color of the glass, when in excess, much easier and better than flattening with the forceps, so often recommended. By completely enclosing the borax bead in the yellow flame this color may be destroyed by reduction of the metal. As nickel gives a too similar bead with borax, this infallible carbonate of soda test is also necessary for absolute certainty. Manganese when hoiled with sulphuric acid may be detected by adding litharge, which changes the solution to pink.

**THE Tombstone Epitaph** gives a detailed account of two most important strikes in the Empire mine on the 400 level. A well-defined vein, six ft. wide, has been cut, from which the assays average \$25.78. This is the only mine on the Arizona belt which has not heretofore proven a producer. It is a Boston incorporation. In the northwest workings of the Good Enough mine, near the Arizona line, a four-ft. vein of ore has been struck, assaying as high as \$4,000. This is in new ground and a most important strike.

In the case of Joseph A. Donobue against the Mariposa land and mining company, of California, and the Farmers' loan and trust company, Judge Evans has appointed Sylvester Hemenway receiver, in the place of R. E. Meyer, removed, at a salary of \$250 a month, with bonds in the sum of \$50,000. Immediately after delivering up possession, R. E. Meyer, the old receiver, has been directed to file his accounts, to enable the Court to make a settlement thereof.

N. E. NELL, who went down to San Jose, Lower California, to take charge of some newly discovered copper mines, was drowned on the 3d inst. on landing freight with a boat.

The Bullionville Smelting Co. are sending plenty of bullion to the Salt Lake market.

## THE PELTON WATER WHEEL.

(Patented, Oct. 26, 1880.)

This water wheel has been thoroughly tested with the Dynamometer, and utilizes 78% of the theoretical power; and underheads of water of 75 to 800 ft. is guaranteed to give better satisfaction than any Turbine or other wheel ever offered to the public. The above per cent. is due to the peculiar shape of the buckets used. They do not reduce the water to a spray, but divide and deflect it outward and backward, in such a manner that a part of the impact and the whole reactionary force are utilized, without any part of the water coming in contact with the bucket following. Furthermore, the per cent. of efficiency remains constant through great variations in the amount of water used. These buckets can be taken off in transportation, and can be replaced by new ones when worn out by sand in the water; also can be applied to wooden wheels when desired.

SEND FOR CIRCULAR.

Orders can be filled at short notice by addressing the undersigned,

L. A. PELTON,  
Camptonville, Yuba Co., Cal.

FOR SINGLE OR DOUBLE SHAFTS, TO WORK TO ANY DEPTH, OF LATE AND IMPROVED DESIGNS, SUPERIOR TO ANY OTHER MAKE; ADAPTED TO THE REQUIREMENTS OF PRACTICAL WORK AND EMBRACING ALL THE IMPROVEMENTS AND SAFEGUARDS THAT EXPERIENCE HAS PROVED VALUABLE IN THIS CLASS OF MACHINERY. MINING CAGES, CAR AND BUCKETS, ALSO MILL AND MINING MACHINERY OF EVERY DESCRIPTION. SEND FOR CIRCULAR. RANKIN, BRAYTON & CO., PACIFIC IRON WORKS, SAN FRANCISCO, CAL.

### A NEW TREATMENT

—FOR—

Consumption, Asthma, Bronchitis, Dyspepsia, Catarrh, Headache, Neuralgia, Debility, Rheumatism,

And all CHRONIC and NERVOUS DISEASES.

PACAGE CONVENIENTLY SENT BY EXPRESS, READY FOR USE

### AT HOME.

A Treatise on Compound Oxygen, giving the history of this new discovery, and a large record of most remarkable cures, will be mailed free to all who ask for it. Also, 'Health and Life,' a quarterly journal, containing much interesting information. Write for it. Address the proprietors, DRS. STARKEY & PALEN, 1109 and 1111 Girard street, Philadelphia, Pa., or H. E. MATHEWS, 606 Montgomery street, San Francisco, Cal., from whom can be procured both information and supplies.

42 years' practical experience; 14 on Pacific Coast.

HERCULES SLAYING THE GIANTS.

## HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

### THE CALIFORNIA POWDER WORKS,

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and HERCULES Powder.  
ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street, - - - San Francisco, Cal

### MOREY & SPERRY,

MANUFACTURERS OF

Gold and Silver Grinding and Amalgamating Machinery

HOWLAND'S PULVERIZER Takes the Place of the Cumbrous Stamp Mill and can be put up in one day ready for work.

IT HAS BEEN FULLY PROVED AND TESTED.

It weighs complete, 7,000 pounds. It costs \$1,500 ready for the belt. Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C. No bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ore, making a simple, cheap and effective mill. It requires twelve-horse power.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies. Iron Work complete for Wood Frames, also.

SPERRY'S  
WROUGHT IRON FRAME  
FOR STAMP MILLS.

Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.

MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

### LEFFEL'S IMPROVED WATER WHEEL.

PRICES REDUCED!

PATENTS REISSUED 1868.

The "OLD RELIABLE" with improvements, making it

THE MOST PERFECT TURBINE NOW IN USE.

Comprising the Largest and the Smallest Wheels, under both the Highest and Lowest head used in this country. Our new Illustrated Book sent free to those owning water power.

Those improving water power should not fail to write us for New Prices, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address

JAMES LEFFEL & CO., Springfield, Ohio,

and 110 Liberty St., N. Y. City.

PARKE & LACY, Sole Agents, 21 and 23 Fremont St., S. F.

### Pacific Rolling Mill Co., SAN FRANCISCO, CAL.

MANUFACTURERS OF

RAILROAD AND MERCHANT IRON,

ROLLED BEAMS, ANGLE, CHANNEL AND T IRON, BRIDGE AND MACHINE BOLTS, LAG SCREWS, NUTS, WASHERS, ETC., STEAMBOAT SHAFTS, CRANKS, PISTONS, CONNECTING RODS, ETC., ETC.

Car and Locomotive Axles and Frames, and Hammered Iron of Every Description.

HIGHEST PRICE PAID FOR SCRAP IRON.

Orders Solicited and Promptly Executed.

Office, No. 202 Market St., UNION BLOCK.

### INGERSOLL ROCK DRILL. PRICES REDUCED.

Parties requiring Drills can get them at agents' rates by applying to

GEO. R. FOARD,

Sole Agent for Pacific Coast.

No. 18 First St., S. F.

The only Depot where Standard Drills and Duplicate Parts can be obtained.

### L. P. DECEN.

MANUFACTURER OF

Also Water-Proof Leather Belting.  
NO. 13 FREMONT ST., near Market, SAN FRANCISCO

### MECHANICS' MILLS.

OUR WELL KNOWN

### WATER TANKS,

Made by machinery, constantly on hand and made to order. PAN STAVES, WOOD PULLEYS and OAK GUIDES a specialty.

WELLS, RUSSELL & CO.,

Mechanics' Mills, corner Mission and Fremont street.

### MENZO SPRING.

Manufacturer of the Best

Improved Artificial Limbs.

OFFICE AND ADDRESS:

9 Geary Street, Junction of Market and Kearny, S. F.

### AMERICAN EXCHANGE HOTEL.

Sansome Street, (Opposite Wells, Fargo & Co's Express), San Francisco.

This Hotel, under the management of CHAS. MONT-OMEY, has been thoroughly renovated, and being in the very center of all the Banks, Insurance Offices and Commission Merchants, it offers special inducements to Merchants from the Interior and Farmers.

Board, with Room, \$1, \$1.25 14 \$1.50 per day. Special rates by the week or month.

FREE COACH TO AND FROM THE HOTEL.

### BOILER COVERINGS.

Plastic Cement and Hair Felt, with or without the Patent "AIR SPACE" Method. Cement ready for use by the barrel.

G. O. FOWLER, No. 413 Pacific St., S. F.

WIND MILL. One of the best made in this State for sale cheap on easy terms. Address, W. T., care of Dwyer & Co., S. F.

**Metallurgy and Ores.**

Mining Engineers and Metallurgists

**JOHN TAYLOR & CO.,**

IMPORTERS OF AND DEALERS IN

**Assayers' Materials,**  
MINE and MILL SUPPLIES,

CHEMICAL APPARATUS AND CHEMICALS, DRUG-  
GISTS' GLASSWARE AND SUNDRIES, Etc.

118 and 120 Market Street, and 15 and 17  
California St., San Francisco.

We would call the attention of Assayers, Chemists,  
Mining Companies, Milling Companies, Prospectors, etc.,  
to our full stock of Balances, Furnaces, Mullies, Crucibles,  
Scorifiers, etc., including, also, a full stock of  
Chemicals.

Having been engaged in furnishing these supplies since  
the first discovery of mines on the Pacific Coast, we feel  
confident from our experience we can well suit the demand  
for these goods both as to quality and price. Our  
New Illustrated Catalogue, with prices, will be sent on  
application.

Our Gold and Silver Tables, showing the value per  
ounce Troy at different degrees of fineness, and valuable  
tables for computation of assays in grains and grammes,  
will be sent free upon application. Agents for the Patent  
Piumbago Crucible Co., London, England.

EDWARD G. DENNISTON, PROPRIETOR.

Awarded First Premium at Every Fair of the Mechanics' Institute  
for the Last Twelve Years.

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-OLYGERINE PATENTS.

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive

**Judson Powder**

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary  
powder wherever it is tried. Triple Force Caps and all Ordes of Fuse.

**BANDMANN, NIELSEN & CO.,**

SAN FRANCISCO, CAL.

**\$1,000 CHALLENGE!****THE FRUE ORE CONCENTRATOR.**

Over 250 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial  
Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.  
Saves from 50 to 100 per cent. more than any other Concentrator in use, and the concentrations are clean from  
the first working.

The wear and tear are merely nominal; the water required is less than in any other wet Concentrator; the power  
required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend  
to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of  
\$1,000 each, and we mean business.

**EXCELSIOR****BLASTING POWDER**

MANUFACTURED BY THE

Excelsior Powder Company.

This is no so-called "safety" Powder, but a powerful ex-  
plosive, and as safe to handle and use as any nitro-glycerine  
Powder on the continent. There is no headache or nausea  
in the use of this Powder, as the noxious fumes are entirely  
done away with. It is put up in cartridges of any size to  
suit consumers and is exploded with cap and fuse, the same  
as any other high explosive. The following testimonial is a  
sample of hundreds of the same tenor being constantly re-  
ceived:

GOLD HILL, August 17, 1880.

AGENT EXCELSIOR POWDER CO. - Dear Sir: - I have used  
your Powder in test cement and hard blasting rock, and find  
it superior to any Powder in use on the Coast. It does  
its work effectually, and does not leave the person using it  
with a severe headache, like the other Powders on the ma-  
jority of miners. I recommend it I would suggest, give  
it a fair trial and I am confident it will speak for itself.  
Wishing your Company success,  
I am respectfully yours, etc.

GEORGE CLARK,

Foreman Sierra O. and S. M. Co

**Scientific and Practical Books  
on Mining, Metallurgy, Etc.**

Published or issued, wholesale and retail, by DEWEY &  
CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Concentration of Ores (of all kinds), including  
the Chlorination Process for Gold-bearing Sulphurets,  
Arsenurets, and Gold and Silver Ores generally, with  
120 Lithographic Diagrams. 1887.

This work is unequalled by any other published, embrac-  
ing the subjects treated. Its authority is highly esteemed  
and regarded by its readers; containing, as it does, much  
essential information to the Miner, Metallurgist,  
and other professional workers in ores and minerals, which  
cannot be found elsewhere in print. It also abounds  
throughout with facts and instructions rendered valuable  
by being clearly rendered together and in simple or-  
der. It contains 120 diagrams, illustrating machinery  
etc., which alone are of the greatest value. PRICE, \$7.50

## PATENTS AND INVENTIONS.

### List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," U. S. and Foreign Patent Agents.]

FOR THE WEEK ENDING MAY 10, 1881.

241,270.—ROLLER SEATE—W. Atin, S. F.  
241,234.—VEHICLE WHEEL—J. H. Bradshaw, San Leandro, Cal.  
241,299.—SWITCH FOR CABLE-WAYS—H. Casebolt, S. F.  
241,427.—FAUCET—W. M. Sack, Oakland, Cal.  
241,466.—FIRE ARM—J. W. Wilson, S. F.

FOR THE WEEK ENDING MAY 17, 1881.

241,430.—FURNACE—J. Enright, San Jose, Cal.  
241,485.—DOOR WICKET—L. P. Garcia & A. W. Baldwin, S. F.  
241,749.—STAMP PROTECTOR—J. L. Lillenthal, S. F.  
241,749.—DRAG SAW—J. W. Swales, S. F.  
24,463.—LASEL—H. Vandre & Co., Oakland, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

### Notices of Recent Patents.

Among the patents recently obtained through DEWEY & CO.'S SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

**STAMP PROTECTOR.**—J. Leo Lillenthal, S. F. Dated May 17, 1881. No. 241,678. This invention is designed as a means for protecting Internal Revenue stamps, employed and need by the Internal Revenue Department for distillers and liquor-dealers, by pasting upon pipes and barrels, or other packages, so the said stamps will not become injured or destroyed during transportation or storage, and in combining with the same a shipping card or ticket. That class of Internal Revenue liquor stamps which this device is especially intended to protect have the stamp number printed upon that portion of the stamp which extends across the center, and when the stamp is pasted upon the package the end portions are pasted down firmly. While this center, which is technically known as the "double back" or "pull back," is left free, so that when the contents of any package are to be withdrawn, that portion of the stamp number may be removed and deposited with the revenue authorities. The device will protect and cover all stamps on packages which are necessary for identification and protection. Its use and employment is a necessity in the shipment of stamped packages from one portion of the country to another, as the stamps become mutilated by rough usage or by rats. The invention provides a protector or mark for the central portion of the stamp and stamp number; and in combination with it, provides a shipping mark or ticket, which may be formed as a part of the protector.

### Our Agents.

Our traveling correspondent, A. Leonard Meyer, now at Hailey, on Wood river, Alturas county, Idaho, had his hand severely hurt by a runaway horse while in Utah, and was laid up for several weeks from the effects of the accident. He is, however, getting on very well now, and shall soon have entirely recovered.

And this reminds us that newspaper agents and correspondents who travel on this coast, do not have a very easy time of it, and their services are perhaps not as much appreciated as they should be. Our agents have to rough it in every kind of way. They have to take all kinds of fare; travel at all sorts of hours; have extremes of heat and cold in one day; arrive strangers in strange towns with no one to welcome them.

These men do a good deal of good to the country. They hunt up all sorts of information about it which a resident would not notice. They bring into public prominence enterprises and plans which would otherwise remain obscure for years. They assist in the development of the country; call the attention of capital to suitable forms of investment; describe the routes of travel, railroads, stage lines, roads, etc. They visit the mountains and the villages; go into the mines and mills; and by their judicious descriptions attract the notice of outside people to the towns. No place that these men visit can fail to be benefited to a greater or less degree.

It is not often, by the way, that a good word is said for the traveling newspaper agent and solicitor. Yet he has many good qualities. He is a shrewd judge of character; and while apt, perhaps, to get rather a superficial view of affairs in his hurry, is pretty certain to get a correct one. If people would but think a moment they would feel that these agents deserve encouragement in every possible way.

AFTER the denial of the motion of defendants for a change of venue in the suit of the city of Marysville vs. North Bloomfield Gravel M. Co., the plaintiff, by leave of the Court, filed an amendment to the original complaint to confine the pleadings to the opinion of the late Supreme Court in the case of Keyes vs. Little York Gold Washing and Water Co. The defendants were granted the statutory 10 days in which to plead an amended complaint.

### "Copp's U. S. Mineral Lands."

The new work\* with this above title has just been issued by Henry N. Copp, and contains 570 pages. It comprises laws, forms, instructions and decisions, rules of practice, etc., etc. The work is a very complete one in every respect, and everybody connected with the mining interests in any way will do well to purchase it. Probably no better idea of the scope of the work can be given than by quoting part of the table of contents:

**PART I—LAWS.** United States Revised Mining Statutes, with extracts from the laws of 1866, 1870, and 1872, following appropriate sections; Laws of 1866 and 1870 in full, for reference; A table of parallel reference of Laws and Revises; Statutes, Acts of Congress in full of February 18, 1873, March 1, 1873, June 6, 1874, February 11, 1875, May 5, 1876, January 22, 1880; Sundry Tunnel Law; Timber-cutting Law; Timber and Stone Law; Saline Law, and Coal Laws of 1864, 1865, and 1873.

**PART II—LAND OFFICE REGULATIONS.** (a) General Circular of instructions; (b) Circular of July 15, 1873, defining valuable deposits and rock in place; (c) Circulars relative to hearings; (d) Circulars relative to surveys; (e) Circulars relative to annual expenditures; (f) Stone and Timber lands; (g) Saline lands and salt deposits; (h) Coal land regulations.

**PART III—LAND OFFICE RULINGS.** (a) All the important rulings under the general laws, chronologically arranged (some 300 pages.) All the decisions under the law of 1866 are brought together, and, as the majority of decisions embrace two or more subjects, no other arrangement can prove satisfactory. A good index will refer the inquirer to all rulings upon a given question. (b) Saline lands and salt deposits (four pages); (c) Coal lands (ten pages.) In preparing these rulings, surplus verbiage has been omitted.

**PART IV—JUDICIAL DECISIONS.** (a) The leading Federal and State decisions in full; (b) Digest of about 200 court decisions.

**PART V—MISCELLANEOUS.** (a) Some thirty-five Forms. Those relating to applications for patent have been revised by C. W. Holcomb, Chief Clerk of the General Land Office, and, until recently, chief of the mining division of that office; (b) Glossary, prepared by Dr. R. W. Raymond, late U. S. mining commissioner. This glossary of mining terms prepared by Dr. Raymond is very complete. He took as a basis the glossary which appeared in Gregory Yale's "Mining Claims and Water Rights in California," and which was prepared by the editor of this journal, Mr. Yale's son. Dr. Raymond has eliminated many Spanish terms and added other terms which have come into vogue since the publication of the original glossary, and has extended its scope.

(c) New Rules of Practice, approved by Secretary Schurz, to take effect February 1, 1881; (d) Full instructions how to examine a mining title. This valuable feature will be appreciated by lawyers, especially those who have lately located in mining communities; (e) The Public Land Commission's Codification relating to mineral lands. It contains numerous references to Court and Land Department decisions under each section.

\*Can be examined or ordered at Dewey & Co.'s Book Department. Price full law binding, \$4.50; half law binding, \$3.

### Tubbs' Hotel.

This hotel has recently changed hands, and has been thoroughly renovated, having been repainted, frescoed and refurnished throughout. Mr. H. S. Greeley, the present proprietor (also of the Galindo hotel, of Oakland), is well known for his thorough knowledge of hotel keeping and for his courtesy and attention to his guests, and is meeting with deserved success at both his hotels.

Tubbs' hotel is within 50 minutes journey from San Francisco. Trains leave Clinton station both to and from every hour, and the street cars to Oakland pass the hotel every half hour. The views of the surrounding country are very beautiful, especially that across Lake Merritt to the hills beyond. We should not omit to mention the stairway fire escape from the upper floor, which preclude all danger to residents from fire.

There is a fine billiard-room, with new tables; good reading-room and sitting-rooms a very elegant ladies' drawing-room, with fine piano; a first-class table is kept; in short, every comfort of a home is to be found here, combined with the freedom of hotel life. The charges are very moderate, and we recommend alike visitors and city residents not to fail to visit this delightful resort. An illustration of the hotel appears from time to time in our columns.

ACCORDING to the Wood River papers, things are booming for prospectors in that country. They swear it is the biggest country on the Lord's footstool.

THE shipments of bullion from Butte, Montana, now average over \$50,000 per week. This will be doubled before fall. The camp is growing rapidly.

THE *Calistogan* says: A third interest in the Rough and Ready mining claim has been sold to certain parties in town; consideration, \$500.

### Bad Timbering in Mines.

The telegraph has brought us news of a disastrous cave at the Golden Terra mine, Terraville, in the Black Hills. The night shift, of 60 men, were just coming on, but only about 20 had entered the tunnel, when a large body of earth fell in at a distance of nearly 200 feet from the mouth, tearing and throwing the timbers at a fearful rate, as far as 100 or 200 feet. One man, Thomas Green, was thrown by the compression of the air nearly 80 feet out of the tunnel against a side wall of an open cut and killed instantly. Two others were blown right through the tunnel. One escaped unhurt, the other was struck by a timber and died. Eleven were buried under the debris. The cave is supposed to be about 250 feet long, 100 feet wide and 80 feet deep, and occurred directly over the large ore chamber, completely filling it. Hundreds of miners were at once sent to the works from Lead and Central Cities, and shifts were changed every 15 minutes, only five or six being able to work on either side of the cave at a time. The tunnel runs entirely through the hill, connecting the Terra and Highland mines. Seven men escaped, with nothing more serious than a few bruises, through the tunnel to the Lead City side of the hill. The nine men who had been imprisoned in the mine were all rescued the next afternoon at 2 o'clock. None of them sustained any injuries. This leaves only three, Thos. Green, Jas. Farley and James Beakey, killed, and five slightly injured. Subscriptions for the relief of those made homeless and destitute have been called for by the press of this Hills, and the people have responded liberally.

It is said no blame can attach to the company or anyone else. We don't believe it. When such a case as this occurs it must be somebody's fault. It is very probable that bad timbering was the cause. It is all very well to be economical, but economy in this respect in a mine is a foolish measure. If we remember aright we have been told that the timbering in this mine was very light, and the accident which has now happened had been predicted. Other mines in the same neighborhood are no better protected. If this accident was due to bad or careless timbering, we believe that heavy damages could be obtained from the company.

### Our Native Woods.

Col. Armstrong of the Santa Rosa Republic writes the following interesting paragraph concerning California forests and lumbering:

There are many valuable timber trees in the Coast range for building and decorating. Beginning with the redwood, it is well known as the very best and cheapest timber for building. The price of redwood boards in this city varies, according to quality and finish, from about \$15 to \$30 per 1,000 ft. Planks and squared timber may be ordered at the mill any desired size, only limited by the capacity of the machinery to saw it. Logs eight ft. in diameter may be sawn into planks; but nobody wants boards eight ft. wide, so the logs over five ft. are generally split into halves or quarters before sending to the mill. This lumber splits true, and works soft and smooth. It is a beautiful cedar color, and very durable. Our redwood forests are probably of more value to the State than all the mines it contains. They are certainly of great use in supplying the everyday wants of improvement, and are a larger factor in the prosperity of our people than the mines are, or ever were, so far as this coast region is concerned.

A vast amount of this valuable timber is annually destroyed by the lumbermen in careless felling, and by fire. Judging by what we have seen in past years, not more than two-thirds of the tall straight trees are safely handled, or cut up clean. True there are shingle mills now working up refuse cuts, and there is springing up a demand for cord wood that pays something for hauling it a mile or two to the railroad. But perhaps nine-tenths of the spoiled trees and waste timber are too remote for such hauling and become food for fire.

Fir is plenty in the same district. It does not possess the durable qualities of redwood for posts, pickets, etc.; but it is hard, strong timber, much used for framing, bridge-building, and, in heavy planks, for sidewalks. It does not grow as large as the redwood, being usually from 100 to 150 ft. in height, and not more than 5 or 6 ft. across the stump. This lumber, in its various rough forms, sells for about \$22 per 1,000 ft. in this city.

Tan bark oak is still very plentiful, though the high price of tan bark is causing the rapid destruction of the timber. Plenty of quarter sections of Government land have been paid for by pre-emptors with the bark found on the land. The wood is the best of fuel. Its grain is variegated and beautiful when worked into chairs, balustrades for stairs, etc. It would be highly appreciated, if better known, for decorative purposes. Plenty of the tree trunks are large and straight enough to saw into flooring and other stuff.

Laurel, or pepper-wood, grows a majestic tree and is found scattered among the hills. The oldest, gnarled trees are the ones producing the best veneers for cabinet work. Straighter trees are in some request for ship building.

Beside the timber mentioned, there are white

and black oak, madrone, etc., staple woods for fuel.

No country is better supplied with useful and ornamental woods than northern California. Building materials are cheaper at Santa Rosa than anywhere in the Atlantic States, remote from the pines. Timber for railroad construction, ties, telegraph poles, and lumber for bridges and depot buildings may also be snatched under the same head.

### News in Brief.

SMALL-POX is spreading in Virginia, Nevada. The Russo-Chinese treaty has been ratified at Peking.

GRASSHOPPERS are doing mischief in Southern Utah.

COL. THOS. A. SCOTT, the great railroad manager, died on the 21st inst.

GROUND broken at Deadwood, D. T., on the Black Hills and Custer City railroad.

It is estimated that 250,000 volumes of the English Testament have been given out.

GRASSHOPPERS are creating much alarm among the farmers of portions of Washington Territory.

THERE are on the railroad lines of California 32,000 carloads or 320,000 tons of wheat, old crop.

SINCE March 30, 1880, there has been 8,113 miles of railroad constructed in the United States.

A CHICAGO dispatch says: The Chinese have formed a Free Mason organization and protective union.

MAYOR KALLOCH, of this city, has been granted six weeks' leave of absence, and has gone East.

THE Nevada and Oregon railroad reports that 100 men, including 30 Chinamen, are at work grading near Reno.

MRS. WM. CHAPMAN died suddenly of heart disease at her home in Josephine county, Oregon, on the 20th inst.

THE Brazilian line of steamers known as the American line has been withdrawn, because foreign rivalry has proven too great.

THE steamship *Ganos*, from Matanzas for Boston, was sunk in a collision near the latter place Friday night. But one life was lost.

RUMOR has it that the contemplated Guatemala Exhibition of 1882 has fallen through, in consequence of the condition of the revenue of the country.

THE steamer *State of California*, over whose non-arrival so much anxiety prevailed, reached San Francisco in tow of a tug. She had broken her main shaft.

THE newspapers published in Eastern Montana claim that more cattle have been killed at the hands of Indians than perished by the cold during the past winter.

JURGENSEN, editor of a socialist paper, the *Herald*, in Copenhagen, has been arrested, charged with inciting to the murder of the king and to establish a commune.

THE new Hungarian loan of £16,000,000 4% gold rentes, has been subscribed many times over, and closes at 3% premium.

SEVERAL well-known Scotch farmers are about to start on a tour through America, with a view of obtaining information in regard to the prospects of agricultural emigrants.

THE unparalleled telegraphic feat of sending 109,436 words from New York to Chicago was accomplished by the Western Union company on Friday night in less than seven hours.

THE Presidents of the various mercantile associations of Boston have called a meeting for the purpose of considering the possibility of inaugurating a world's fair in that city in 1883.

THE Trustees of the Napa Insane Asylum have purchased 402 acres of land from W. H. Coombs for the sum of \$12,000. This makes the Asylum property include about 600 acres.

SOME small pebbles have been found in the vicinity of Eureka, Nevada, which look like diamonds in the rough, and have been so pronounced by local experts. They are to be tested.

THIRTY Red river carts, accompanied by their half-breed drivers from the Judith basin, lately came to Helena, Montana, with 600 buffalo robes, besides skins and furs, dried meat and pemmican.

CAPT. LAFAYETTE ALLEN, a veteran of the Mexican war, and a pioneer of southern Oregon who fought in the early Indian wars, died at his home on the lower Applegate creek, Jackson county, last week.

AT the annual meeting of the stockholders of the Atlantic and Pacific Railroad Co., held on the 19th, at Boston, Charles Nickerson was re-elected President and E. F. Winslow, Vice-President. Both officers held over.

AN investigation of the U. S. Treasury Department is now in order. It is charged that the custodian has been purchasing furniture, carpets, etc., at exorbitant prices, and buying things at private sale instead of by contract.

THE wages offered for first-class seamen to brave the rigors of an Arctic climate on the next expedition in search of the *Jeannette* were so low that it was found impossible to obtain the men in this city, so they will have to be obtained East.

### California Brass Foundry,

No. 125 First Street, Opposite Minna.

SAN FRANCISCO, CAL.

All kinds of Brass, Composition, Zinc, and Babbitt Metal Castings, Brass Ship Work of all kinds, Spikes, Sheathing Nails, Rudder Braces, Hinges, Ship and Steamboat Bells and Gongs of superior tone. All kinds of Cocks and Valves, Hydraulic Pipes and Nozzles, and Hose Couplings and Connections of all sizes and patterns, furnished with dispatch. PRICES MODERATE. J. H. WEED, V. KINGWELL.

### California Machine Works,

WM. H. BIRCH, Prop'r.

119 Beale Street, San Francisco.

General Mechanical Engineer and Machinist. Steam Engines, Flour, Quartz and Mining Machinery. Sole manufacturer of Brodie's Patent Rock Crushers and Steel-Faced Tappets. Agent and Manufacturer of F. A. Youse's Patent Steam Packing Rings for Steam Pistons. The best ever invented; can be applied to any Engine Piston and give entire satisfaction to those using. Steam, Hydraulic and Sidewalk Elevators. Repairing promptly attended to.

### STEAM ENGINES AND BOILERS

Of all sizes—from 2 to 60-Horse power. Also, Quartz Mills, Mining Pumps, Hoisting Machinery, Shafting, Iron Tanks, etc. For sale at the lowest prices by

J. HENDY, 49 and 51 Fremont Street, S. F.

THOMAS THOMPSON.

THORNTON THOMPSON.

THOMPSON BROTHERS,

EUREKA FOUNDRY,

129 and 131 Beale St., between Mission and Howard, S. F.

MANUFACTURERS OF CASTINGS OF EVERY DESCRIPTION.

### CALIFORNIA

## Electric Light Company.

Owners of the Brush System of Electric Lighting for the Pacific Coast.

Apparatus for sale for Mines, Mills, Manufactories, etc. Flaming Machines and Machines for treating Ore manufactured to order.

Electric Light furnished on all the principal streets of the city.

Office—No. 119 O'Farrell Street,

SAN FRANCISCO, CAL.

### NEW MINING FIELDS.

Prof. Hayden's Geological survey of the northern wilds, comprising his explorations in the Big Horn, Gray Bull, Yellowstone and Sun River Countries, Wind River, Teton, Little Rocky and Bear Paw Mountains. Their geology and physical features. Where the survey found "paying prospects," going from 6 to 25 cents in gold to the pan. Immense gravel bars prospecting 8 and 10 cents per pan. Water abundant for hydraulic mining. Extensive gold and silver bearing quartz lodes, one mammoth ledge assaying \$18.90 in free gold per ton, from surface croppings. The classes of country rock peculiar to each section, which interest the miner, as being the most congenial for the existence of rich veins and placers. A valuable work (with map), forming a complete intelligible, systematic guide and companion for miners and gold hunters, desirous of prospecting in the northern Rockies and localities mentioned. Terms, \$5 per copy; 5 copies for \$20. Address J. A. CAMPBELL & CO., Evanston, Wyo. Ter. Box No. 119. [Mention this paper.]

## DEWEY & CO.'S

Scientific Press

Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

## No Drouths! Sure Crops!

**READING RANCH,**

Shasta Co., Cal.

**Good Land!****Sure Crops!****HEALTHY CLIMATE!****Prices Low. Terms Easy.****TITLE PERFECT.**

The Reading Ranch, in the Upper Sacramento valley, originally embracing over 25,000 acres of choice grain, orchard and pasture land, is now offered for sale at low prices and on favorable terms of payment, in subdivisions to suit purchasers.

The ranch was selected at an early day by Major P. B. Reading, one of the largest pioneer land owners in California. It is situated on the west side of the Sacramento River and extends over 20 miles along its bank.

The average rainfall is about 50 inches per annum, and crops have never been known to fail from drouth.

The climate is generally healthy. The near proximity of high mountain peaks give cool nights during the "heated term" which occurs in our California summers. Pasturage, wood and good water are abundant. The tillage land is mostly level, with complete drainage.

Figs, Grapes, Peaches, Prunes, Almonds, English Walnuts, Apples, Currants, Berries and other common fruits can be raised with success on most of the tract without irrigation. Also, Alfalfa, Vegetables, Corn and all other cereals ordinarily grown in the State.

The soil throughout the tilled portions of the ranch proves to be of great depth and enduring in its good qualities. It is quite free from foul growths. The virgin soil among the large oak trees on the bottom land is easily broken up and cultivated.

The title is U. S. patent. Prices range principally from \$5 to \$30 per acre.

The California and Oregon railroad traverses nearly the entire length of the tract. There are several sections, stations and switches, besides depots at the towns of Anderson and Reading, all of which are located within the limits of the ranch.

The Sacramento River borders the whole tract on the southeast. Its clear waters are well stocked with fish. Good hunting abounds in the surrounding country.

Producers have a local market, which enhances the value of their produce. The railroad transportation route is level throughout to San Francisco. A portion of the land is auriferous and located near rich mines now being worked. Land suitable for settlers in colonies can be obtained on good terms.

Town lots are offered for sale in Reading, situated on the Sacramento river, at the present terminus of the railroad. It is the converging and distributing point for large, prosperous mining and agricultural districts in Northern California and Southern Oregon. Also lots in the town of Anderson, situated more centrally on the ranch. Lots in both these towns are offered at a bargain, for the purpose of building up the towns and facilitating settlement of the ranch.

Purchasers are invited to come and see the lands before buying here or elsewhere. Apply on the ranch, to the proprietor.

**EDWARD FRISBIE,**

Anderson, Shasta Co., Cal.

Location of Shasta County.

Shasta County lies not far from midway between the two most important ports on the Pacific shore, i. e., San Francisco and Portland, Oregon, and directly on the route from Mexico to British Columbia. The town of Redding, at present, and probably for years to come, the head of railroad transportation on the California side of the mountains intervening below Oregon, is distant from San Francisco by railroad (via Vallejo) 255 miles; from Sacramento City, 160 miles; from Marysville 117 miles.

LAND FOR SALE OR RENT IN SUB-DIVISIONS.

## Quicksilver Feeder for Gold Mills.

When automatic ore feeders first came into use, no one believed in them. Everybody thought that it would be necessary to have a man with a shovel standing around to help the feeder; that machinery could not do the work as well as a man. It has been found by experience that automatic feeding is the best; that the machine not only does its work as well, but better than, the man, and now all mills use automatic ore feeders because more ore can be put through in a given time with the same power than under the old system.

People nowadays want to make machinery on pretty much everything, and they succeed very well. The latest thing in automatic mechanism for quartz mills is a quicksilver feeder, the invention of Mr. P. C. DuBois, of No. 18 Fremont St., in this city. We illustrate this device on this page.

This machine is for feeding quicksilver to the mortars of gold mills. It is so connected to the cam shaft, that each revolution of the large ratchet wheel, which can be regulated to revolve once in one, two, three or four minutes, as desired, dips a small cup into a reservoir of quicksilver, and, by a trip of the cam, empties the contents into a pipe leading down to the mortar, supplying an exact quantity at regular intervals, superseding the ordinary hand feeding, which is of necessity subject to great irregularity, and liable to neglect. It renders the amalgamation of all the gold in the pulp equally certain and perfect.

The mechanism to produce this depression and elevation of the cup, is driven by the cam shaft, similarly to the self-feeders, over which so much ingenuity has been expended to regulate the delivery of ore to the mortars. As it is to be desired to have the ore go in constantly and regularly, so it is equally desirable to have the mercury fed constantly and regularly.

Every mill man knows the great importance of ascertaining just the right quantity of mercury necessary to be fed to amalgamate all the gold; and when ascertained, of keeping just that quantity fed to the mortars per hour or per day. If not enough mercury is fed, the amalgam inside and outside becomes too hard and coated with sulphurets, consequently will not catch mors gold or amalgam. If too much mercury is fed, the inside amalgam softens and breaks down. It granulates, after which it is about impossible to catch it again. Likewise, the outside plates become so soft that the sand rapidly wears, and carries away what amalgam has already caught. Once the necessary quantity is determined, regularity of feed is the thing desired.

A chief point of excellence of this machine is, that it allows the quantity of mercury which would be otherwise fed in mass, in one hour, to be subdivided into a number of small portions, and fed almost continuously; i. e., from every one to four minutes. As the gold goes in, and also out of the mortars continuously, it is necessary, in order to effect the best amalgamation, that the quicksilver should go in continuously.

The second point of excellence is, that it renders the feeding of quicksilver practically perfect, as to regularity. A superintendent can adjust the feed to suit the ore being worked, and feel certain that a regular, uninterrupted feed will be kept up during his absence, which is impossible to attain under the general method of hand feeding. It places the feeding of a quantity of quicksilver proper for taking up all the gold in the ore, under the control and knowledge of the superintendent alone, and that, with but a few moments of his attention each day.

The reservoir of the machine holds 25 lbs. of mercury—a quantity sufficient for some weeks' work. A lid fastening on top of the tank keeps all secure. The cup which throws out the mercury can be replaced by a larger or smaller one, as the ore requires more or less mercury; several sizes of cups go with each machine. The frequency of feed is regulated by turning a nut, which controls the thrust of the bar that drives the ratchet wheel; thus making the ratchet pass either one, two, three, or four teeth space, at every revolution of the cam shaft.

## Low Grade Ores.

The problem of working the low-grade ores of the Comstock being solved, hundreds of mines in other places are to be worked in the same way. But this problem has been studied long and earnestly, more attention, however, having been paid to it within the past two years than for a long time. A communication throwing a great deal of light upon the subject is one written by Mathey, Kustal & Riotts, of New York, to J. Aron, Esq., and which is as follows:

We beg respectfully to submit the following figures: We have concluded not to weigh down this statement of facts by a detailed report of our experiments, futile some, experimental and on false scent others, and repetitions the most. We would merely say that we have made over 100 assays, 35 wet concentration tests, three dry and one combined test.

We received five boxes of ore marked re-

The 47.3 tons of dust can be concentrated down to 1.83 tons of concentrates, containing \$285.22 gold and \$293.61 silver; total, \$578.83. We have then a total yield of concentrates, by the dry process, of 2.9 tons, containing \$670 gold and \$258 silver; by the wet process, 1.83 tons, containing \$285 gold and \$293 silver; total, \$955 gold and \$551 silver, the gold being a percentage of 88% and the silver of 61%, or a grand total of \$1,506 out of a possible \$1,992, equal to 76% of all the precious metals.

We would state that from the best sources of information as to the cost of concentrating wet and dry, we believe that in a 100-ton mill, one ton can be concentrated by either method for \$1, and by the two methods combined for \$1.50. It is further possible that Mr. Krom, to whom we are indebted for the use of his excellent air concentrating machinery, may be able, as he thinks he is, to finish the working of this dust as successfully as was done by us by water.

Considering the astonishing results, we would counsel you to have tests made on a working scale—say that a car-load from five well-devel-

DUBOIS' AUTOMATIC QUICKSILVER FEEDER.

spectively Nos. 1, 2, 3, 4 and 5, which we find to contain, per manifold assay:

	Silver.	Gold.	Total.
No. 1, Savage ore.....	\$13.25	\$3.02	\$16.27
No. 2, Hale & Norcross ore.....	6.28	1.88	8.16
No. 3, 4 and 5, forwarded from the bonanza mines, Con. Virginia and California, under instructions John Mackay.....	0.11	10.81	10.92

Box No. 1 was concentrated so that 100 tons, containing \$1,885 silver and \$302 gold, total \$2,187, gave two tons of concentrates, assaying per ton \$578.24 silver and \$108.06 gold—total \$686.30 per ton, or two tons, \$1,372.60, equal to nearly 63%.

Box No. 2 was concentrated so that 100 tons, containing \$628 silver and \$188 gold, total \$816, gave one ton of concentrates, containing \$422, equal to 52%. [This was the first box treated, being the poorest ore, and we are confident that, with our present experience, we could reach the same percentages as with box No. 1.]

Boxes 3, 4 and 5 were joined and treated as one—first, exclusively by the wet way. Our trials resulted as follows: 100 tons, containing \$911 silver and \$1,081 gold, total \$1,992, yielded 2 7/8-100 tons of concentrates, which contain per ton \$144.55 silver and \$276.38 gold—total \$420.93, or total value of 2 7/8-100 tons of concentrates, \$401.71 silver and \$768.40 gold—total \$1,170.11, or equal to about 58%.

Second.—Dry concentration test made on ore from boxes 3, 4 and 5, mixed. One hundred tons crushed through a No. 4 screen, and worked upon a "Krom" concentrator will yield:

	Tons.	Silver.	Gold.
Dust.....	47.3	containing	\$539.00
Fine Tailings.....	35.3	"	66.00
Coarse.....	14.50	"	42.30
Concentrations.....	2.9	"	268.00

Totals.....100 tons "\$905.30 \$1,086.81  
Showing that 100 tons contained originally \$1,992.11 of gold and silver.

## A Needed Cable Connection.

While Cyrus W. Field was on his recent journey around the world, it became necessary to send a telegraphic dispatch to him from New York, which should reach him at Yokohama. When the San Francisco steamer arrived with him on board, he was handed the dispatch as soon as he went on shore, but by what a roundabout journey it had come. It had been sent from New York to Cape Breton, thence under the Gulf of St. Lawrence to Newfoundland, and across Newfoundland. It had been flashed thence under the Atlantic Ocean to Ireland, across Ireland and under the Irish channel to England, across England to Plymouth, under the Bay of Biscay to Lishon, Portugal, thence to Gibraltar, thence to Malta in the Mediterranean, under the Mediterranean to Alexandria, Egypt, thence across the Isthmus of Suez, by the great pyramids, and under the Red sea to Aden, Arabia, thence under the Indian ocean to Bombay, across Hindoostan to Calcutta, under the Bay of Bengal to Penang, thence through the Straits of Malacca to Singapore, near the equator, thence under the China sea to Hong Kong, along the coast 1,500 miles to Shanghai, by cable under the Yellow sea to Japan, and thence across the beautiful hills of Japan to Yokohama.

Now all this roundabout journey could be saved were there a cable under the Pacific ocean from San Francisco to Yokohama. That cable is really needed to complete the electric circle of the world. Surveys of the bottom of the Pacific ocean have been made by Government expeditions, soundings having been taken on several lines. One line was from San Francisco to Yokohama; another from San Diego to Yokohama; another from Cape Mendocino to Yokohama; still another survey was made from Sitka across the Aleutian archipelago and so to the Japan side.

It is not probable that immediate steps will be taken to put a cable across the Pacific; but at some future time there is little doubt but it will be laid.

## Mining Titles in Alaska.

Mines are being taken up in Alaska under the United States mining laws, the same as they are anywhere in the United States. This title is only possessory, however, and local laws must be strictly obeyed. The Commissioner of the General Land Office, in reply to inquiries as to mineral lands in Alaska, says: "It is held by this office that the mineral lands of the public domain in Alaska are subject to exploration and occupation by citizens of United States and those who have declared their intention to become such. The Territory of Alaska has not been established as, or annexed to any surveying district, and no way has been provided by law whereby lands therein may be purchased. It will, therefore, appear that title to mineral land cannot, under present legislation, be acquired from the United States."

This means of course that, as no surveys have been made, no "corners" established, and no mineral surveys deputized up there, plats cannot be made upon which patents can be taken out. But as people here get along very well without a patent until they want to sell, they will probably get along up in Alaska for awhile as they are. Let them find good mines and it will not be long before means will show themselves by which they can get good title to the mines.

The American Institute of Mining Engineers met at Staunton, Va., this week. Wm. Metcalf, of Pittsburgh, President of the Institute, was first welcomed in the opera house by Mayor Balthus, and then A. H. H. Stuart, Secretary of the Interior under President Filmore. President Metcalf enlarged on the great mineral resources of the Virginia section, which are being entirely neglected in favor of the discovery of minerals in rocky peaks in the West, and in favor of arid plains.

The mine-jumping season opens up briskly in the Black Hills, Dakota.

The Grand Dipper, says the Tomahstone Daily Epitaph, has been handed, by telegraph, to New York parties, for 30 days, the consideration being \$40,000. The party holding is C. M. Bullard, of Tomahstone. Thus one by one, Eastern men are picking up the good mines of the district.

## Copper Smelting—Its History and Processes.—No. 8.

[By HENRY HUSSEY VIVIAN, M. P.]

I must now return to our regular copper smelting process. We have advanced to "white metal," pure (or nearly so) sulphide of copper of, say, 75%—Le Play gives it as high as 77.4%, with 0.7 iron, and 21% sulphur. The next process is what we call "roasting," during which the whole of the sulphur is expelled and the copper reduced to an impure metallic condition known as "blistered copper." Le Play's analysis gives it as 98.4% copper, 0.7% iron; nickel, cobalt, manganese, tin and arsenic, 0.7%; sulphur, 0.2%. It is very remarkable how completely the sulphur has been driven off. This "roasting" process is a very beautiful and delicate operation; and as I am not aware that any thoroughly good account of it exists, I think it will be interesting and instructive if I read a description of it by our Mr. William Morgan, who has for 47 years managed our Hafod Copper Works with the utmost ability and intelligence: Copper Roaster.

"The material operated on in these furnaces consists of white or pimpled metal furnace—regulate from the selecting process, as well as the metallic bottoms from the same process. In the old method of smelting, for ordinary tough copper, no selecting process was adopted, but the metal just as it came from the metal furnace was used, as is now done, both for tough and best selected copper. The pigs of white metal from the metal furnace are broken into large lumps and introduced into the roasting furnace by means of a paddle, and piled up as high as possible in the middle of the furnace. The temperature of the furnace is raised very gradually, so as to produce a very slow fusion, the melted metal falling down in drops, all the while subject to the oxidizing action of two streams of atmospheric air, introduced through two holes (plug-holes) at the back of the furnace, one in either side of the bridge. After the whole has been melted down, the temperature is considerably raised (the air-holes being closed up for this purpose), and the surface of the melted metal freed by 'skimming' from it any slag floating on the face of the charge. The air-holes are then again opened, and as also the head of the fire-place, and the charge cooled down till quite 'set' or hard. During this operation, called 'setting,' the whole charge becomes a spongy mass, and swells to twice or thrice its original thickness when in a melting state. The theory of the roasting process is just this: When sulphide of copper in a melting state is exposed to the action of a current of atmospheric air, decomposition of the sulphide occurs and sulphurous acid gas and oxide of copper are the result. The thin film of oxide of copper produced on the surface is immediately acted on by the sulphide of copper with which it is in contact, and sulphurous acid and metallic copper are the result, the gas passing off through the chimney, the metallic copper from its greater specific gravity falling through the melting mass to the bottom of the furnace, where it is protected from further oxidation. In the production and reduction of the oxide of copper, dense volumes of sulphurous acid escape, and, as the reduction takes place mainly under the surface of the melted metal, the gas resulting from this reduction forces up the cooling metal, until the whole mass assumes the spongy consistency above referred to. When the whole charge has been thoroughly cooled down, so as to become black and hard, the temperature is again raised, but very slowly and gradually as at the first. The object both of the first slow melting and the subsequent remelting of the cooled and raised mass is the production of surface action. In this way, almost every portion is brought under the oxidizing influence of the atmosphere. "Generally speaking, long before the whole of the charge has been remelted, the experienced workman finds, from the large production of oxide of copper, that it is necessary to cut off all further access of atmospheric air, to prevent the whole or a large portion of the charge from becoming oxidized. If the oxidizing process has been conducted first to the right point, it will be found, after the whole of the charge has been melted and the surface freed from slag (which is mainly silicate and aluminate of copper), that the copper when tapped into pigs and cooled has a smooth, blistered appearance, which appearance has given a name to the product of 'blistered' copper. This process occupies 24 hours, and the charge varies from 2½ to 4 tons of copper."

This process is essentially South Welsh, although it is now of world-wide use.

The system of concentration from ore-furnace regulus to black copper varies somewhat in continental works; but it may be generally described as consisting of first burning the regulus repeatedly in heaps or in kilns, and then melting it in a blast furnace, whereby a portion of the copper contents is obtained as black or impure copper of 90% to 95%, with about 3% iron and 1% sulphur, while the remainder of the copper flows out as regulus varying from 51% to 61% copper, 16% to 18% iron, and 20% to 24% sulphur. It will be observed that the blast furnace, owing to its reducing action, produces at one and the same time black copper and regulus never exceeding 61%, while the reverberatory furnace gives one pure product of 75%, which is easily and cheaply reduced into copper of upward of 98%. The superiority of our process over the other is now universally recognized;

and our process has been substituted for the old continental system, I believe, in most works.

The same observation applies to the final process of refining. Here again, I think, I cannot do better than read to you an admirable description of our refining process, written by Mr. William Morgan, who has been a practical refiner all his life, rather than attempt to write one myself.

### Refinery.

"The material dealt with in this refinery furnace is the 'blistered' copper produced in the roaster furnace, and contains from 96% to 98% of copper. The charge occupies 24 hours and weighs from 9 to 10 tons. It is melted during the night, and remains several hours in the furnace in a melted state. The first operation in the process of refining is the skimming off from the surface of the copper the slag which has been produced in the melting of the charge, in order to facilitate the separation of the last portions of sulphur from the copper. To ascertain when the copper is 'fine,' or when it is perfectly free from sulphur, a portion is taken out in a ladle and allowed to cool. If it still contains sulphur, the copper rises in the center of the ladle, or bubbles out over the surface of the set portion, or shows a number of black spots, generally forming a circle according to the quantity of sulphur still left in the metal. When perfectly free from sulphur, there occurs a depression in the center of the copper in cooling, called the 'set.' When it has arrived at this state, the copper exhibits in the fracture a dull red appearance, and is very brittle and unmanageable. In this state, the copper contains a considerable quantity of protoxide of copper, which has been taken up or absorbed by the melting mass as quickly as formed at the surface. In most cases, it reaches the point of saturation by the time the whole of the sulphur has been driven off, to effect which the surface of the copper is left exposed to the action of the air. The next operation is a reducing or deoxidizing one—to convert the oxide of copper, which the copper holds, into the metallic state. The surface of the charge is covered either with stone coal or charcoal; and in order to bring every portion of the mass under the influence of the reducing covering on the surface of the charge, a pole of hard wood is pressed down into the melting mass, and the ebullition caused by the escape of the gases from the burning pole so stirs the whole mass that gradually every portion of the charge is brought into contact with the carbonaceous covering, when the oxide of copper yields up its oxygen to the carbon on the surface, and the whole mass becomes malleable. The changes which take place during the 'poling' process are ascertained by frequently taking small portions of the copper, and examining the fracture, which, when the process is complete, is smooth and silky. If this process of poling be carried too far, the whole mass suddenly becomes 'overpoled,' in which state the color of the copper becomes much whiter in the fracture, and the copper assumes a fibrous, crystalline structure when broken, and when ladled into a mold, on setting it rises in the center, just as silver does when cooling in a test. Whatever may be the cause of the appearance or condition which is thus called 'overpoled,' whether from the copper taking carbon into its composition, or from its being deprived of the whole of its oxygen, the means of remedying the matter is the exposing of the surface of the copper again to the action of the atmospheric air."

### The Continental System

Was to melt the black copper in a shallow 'hearth,' called a Gaarheerd, like a blacksmith's forge, by means of a blast issuing from a sharply inclined tuyere, and impinging on ignited charcoal. Slag forms on the surface of the copper, and is from time to time removed. Tests of the condition of the copper are taken; and when these tests indicate that the copper is fine, the blast is stopped, and either the copper is ladled out and cast into molds or taken off in round, thin masses ('rosette' copper) as the trade may require.

We have now obtained our copper in a fine and marketable state, containing at least 99½% of pure copper. But what have we got?

### Is It Pure Copper?

Is it in a marketable state? I am almost disposed to tell you that no 10 persons in this room differ more from each other than perhaps the quality of 10 succeeding charges of copper made by a copper smelter differ from each other. Mind, I speak critically, not with the enthusiasm of youth, which thinks every face beautiful. I speak of minute differences of quality, generally of no moment, but sometimes of very great moment. I think if I were to ask Mr. Morgan what had been the chief labor of his life, he would reply, "To make good copper." I am sure it has been one of my most constant problems. Now, I have caused a few specimens to be prepared, which will show you upon what minute quantities of what our friend, Joachim Gans, 300 years ago, not inaptly called "corrupt humors," which we should now call "impurities," the quality of copper turns. Let me first say that copper may be of first-rate quality for all copper uses, and yet very inferior when used for making brass; and when I tell you that nearly one-half the copper produced in the world is used for the latter purpose, you will at once appreciate the enormous importance of producing copper of such a quality as to render it available for that manufacture. I well remember when our copper was never tried for brass before it left our works; indeed, I myself introduced the practice even before I took management of them some six-and-thirty years ago.

Many was the cargo of copper we had thrown on our hands by the French brass-makers in those days, and a very unpleasant business it was. We, however, very soon introduced a perfect system of trials for quality which has enabled us to avoid such annoyances. In very early days, I took in hand a series of synthetical trials, which proved of great value. I found chemical analysis slow and most unsatisfactory; traces of this, that, and the other impurity were reported; but who could say to what extent the quality of the copper for one use or another was really affected? It occurred to me that the true way of solving the difficulty would be to take the best copper I could get, and make it bad by various known mixtures of impurities; and I soon found that I was thus enabled to unravel much of the mystery of quality. For the purpose of my lecture to-night, I have caused a few of these synthetical trials to be repeated, and here they are. I do not present them to you as complete or exhaustive, but rather to illustrate this branch of my subject.

(TO BE CONTINUED.)

### Means of Desulphurization of Ores.

The desulphurization of ores is affected: a. By heating with free admission of air. This is the common way of "roasting," and the most important, and is effected either in kilns, heaps, etc., or in reverberatory furnaces. As soon as the sulphureted ore is heated to a certain degree, one part of the sulphur escapes as sulphurous acid; another is converted into sulphuric acid. Some sulphurets (iron pyrites) lose their sulphur without the application of heat, being decomposed by exposure to the action of air for a long time. This way is sometimes practiced on gold-bearing pyrites. b. By heating with exclusion of air. Only the sulphides of gold and platinum are perfectly decomposed by this method. Other sulphureted ores lose their sulphur only in part, being reduced to a lower state of sulphide. Sulphurets of silver (Ag<sub>2</sub>S) remains undecomposed. Cinnabar, sulphide of antimony (Sb<sub>2</sub>S<sub>3</sub>) and sulphide of arsenic volatilize unchanged. Iron pyrites (FeS<sub>2</sub>) gives up 23% of its sulphur, being reduced to magnetic pyrites, and, by a strong heat, to proto-sulphide of iron (FeS), not further reducible. Also sulphide of zinc (zincblende) remains undecomposed. Copper glance retains its sulphur, and copper pyrites loses only one part of the sulphur which is combined with the iron in it. Galena (PbS) is reduced to a lower state (Pb<sub>2</sub>S), a part of the lead separating out in a metallic state (Pb). c. By superheated steam. Sulphurets not evolving sulphur by the last process lose their sulphur slowly on the application of steam, sulphureted hydrogen and sulphurous acid being formed. Experiments made by Regnault showed that desulphurization is effected more perfectly if air is admitted. Roasting in reverberatory furnaces is always effected by the oxygen of the air and by steam, as there is no fuel used which contains less than 25% to 30% of water. Superheated steam has been tried in different ways on sulphurets with the highest expectations, but with no better results for practical use than are given in the ordinary way by the steam obtained from fuel. It may be useful in many instances to have more steam than is true obtained, but this increases considerably the expense of roasting; as, for instance, in Patena's application of steam in roasting silver ores, tried principally with the intention of expelling antimony, arsenic, etc. Another application of superheated steam, with exclusion of air is Hagan's method, which may prove successful on pyritic ores, having at the same time the advantage of being a very cheap method. d. By heating with metals, alkalies or alkaline earths, for which the sulphur has a greater affinity. The affinity of sulphur for the following metals decreases in the order in which they stand, being strongest for the first and weakest for the last: Copper, iron, tin, zinc, lead, silver, antimony, arsenic. Each of these metals can be desulphurized by the next preceding, though with difficulty; but more easily by one further off. Practical use of this property is made in smelting galena with the addition of metallic iron or iron ore. Sulphide of silver in crucibles is decomposed by stirring the liquid with red-hot iron. In a cold way silver sulphurets and chlorides are decomposed by iron in amalgamating pans, the chlorides by iron and quicksilver. Quicksilver is obtained from cinnabar by heating the latter with lime, which takes up the sulphur, etc. e. Carbon has no great affinity for sulphur; the use of charcoal for desulphurization of ores is therefore an inferior method. So is also the use of carbonic acid.—Kustel's Roasting of Gold and Silver Ore.\*

\*This work may be had of Dewey & Co.'s, Book Department.

### The Sweetwater Mines.

H. G. Tobler, the well-known prospector, has returned from a trip to the Sweetwater mines. He spent nearly a week in inspecting the country round about what is known as the Charley Willard discovery. In answer to a question Mr. Tobler said he did not desire to say anything that would be likely to cause a rush to Sweetwater, nor did he desire to say anything to deter prospectors from going there. He thinks all the geological conditions of that section are favorable for a good mineral country, and says it is a good place to prospect. A ridge or chain of low hills skirt the valley, run north and south parallel to the main chain of the Sweetwater mountains and form the first

bench or plateau in the ascent of the range, other benches or plateaus rising successively one above the other far above the timber line and into the region of perpetual snow, or to an altitude of from 13,000 to 14,000 ft. above sea level. About the summit and far down the northerly slopes as well as on the higher plateaus, the snow is still very deep, and the face of the country is consequently not visible to the eye nor accessible to the pick of the prospector. There are about fifteen prospectors now in the vicinity of the Willard find. The foothill chain is of porphyry formation. Mr. Tobler says Charley Willard has a ledge that crops out prominently in this formation and looks well. He is uncertain as to the true width of this vein, and knew nothing of the assays it had given, but says it is a large vein of calico quartz shooting up from the porphyry country. Free Press.

### Our Scenery as One of Our Resources.

It is hard to bring magnificent scenes to measurement by the industrial standard. At first thought it would seem to be a profanation of nature, as estimating the painter's masterpieces by the square-yard is an insult to art. And yet this is something of an industrial age, and the suggestion that there is business in a thing, means more to many people than a hint of the presence of the loftiest sentiment or the deepest emotion. It is sometimes of advantage to a writer that there is such a vein in men's minds, for those of us who are denied the power to picture beauty or frame tributes to sublimity find our pencils moving very freely to the jingle of the coin. Therefore, with due respect to the poetry which others can voice in praise of California scenery, we would mention its value as one of the material resources of our State, which may be made to contribute far more than it does to the prosperity of our people.

It is conceded by those who have traveled that California has varied scenery of sea coast and plain, and hill and mountain, which no similar area on the globe can surpass. It is also true that these gems are arrayed in a setting of genial climates as peerless as themselves. In the vernacular of the showman, the State has peculiar "attractions," and people come from the uttermost parts of the world to see them. The result is that California has achieved an enviable position in art and literature; other results are that all visitors bring money which ministers to the success of our various productive enterprises, and many of them, won by the beauties of earth and air which they sought from afar, make the State their future abode, and bring their capital and their energy to aid in the development of our resources. In any way in which it may be viewed, California scenery is of inestimable value to her name and fame, and as an agency in industrial development, should not be overlooked.

We all know that Switzerland, Bavaria, Savoy, portions of Austria and France and other countries, derive a large part of their revenue from the expenditures of tourists. France, it is urged by some, could never have paid the enormous war indemnity to Prussia but for the steady tide of tourists pouring into her gates and dispensing their wealth upon all classes of producers. California can surpass all these European countries in embodiments of the sublime and the beautiful. The Alps, with all their glaciers and wonderful heights, have no such vertical walls or magic waterfalls as Yosemite. They have no El Capitan that would require 30 Palace Hotel buildings, one above the other, to form the corner wall. They have no South Dome, upon whose vertical edge one can sit and his limbs will hang over a precipice of 5,000 ft. And these are but items in the great list of wonders in the valley. Beyond the confine northward and southward to the ends of the State there are other scenes which entrance the beholder and dwell in his speech to the end of his life.

It is eminently fitting that the State should have a care for the perpetuation of its natural inheritance, and should prepare for continual benefits from its unceasing and increasing charm for tourists. That our scenery is each year yielding us returns can be seen by the report of the Yosemite Valley Commission, and what is learned from the record of the valley is to a certain extent applicable to all our greater scenes. J. M. Hutchings, the able guardian of the valley, and whose voice and pen first introduced its grandeur to the world, in his report last December, shows that 25,518 persons had visited the valley during 16 years. These persons spend during their stay in the State, and irrespective of railroad fares, etc., an average of \$600 each, which being distributed among the smaller industries of the State has produced much comfort to many of our people. It may be fairly expected that the opening of new railroads from the East to this coast and the increased travel which will result, will make our valley resource still more valuable.

It is wise therefore that the State of California into whose charge the valley has been given, should take measures to fit the region for the fullest enjoyment of tourists. There will be \$25,000 expended for the improvement of the valley, the purchase of trails, etc. This sum judiciously expended as we expect it will be, will add greatly to the attractiveness of the valley.

MECHANICAL

PROGRESS.

Straw Lumber—Its Economy.

We have already, in these columns made allusion to the new device of manufacturing lumber from straw—the invention of Mr. S. H. Hamilton of Lawrence, Kansas. Mr. Hamilton had worked up quite a business; when, a short time since, his factory was destroyed by fire. He was turning out, at the time, 20,000 ft. a day and had orders on hand for about 10,000,000 ft. The *Northwestern Lumberman*, speaking of this novel manufacture, says:—

“There can be no question that the straw lumber is admirably adapted to many kinds of finishing work, barrels, table and counter tops, fine doors and ornamental work, and we are assured that it can be produced and sold in competition with the finer grades of pine, or in competition with wide walnut, at about one-half the price of the latter. The standard manufacture is in widths of 32 inches, a length of 12 ft., and a thickness corresponding to that of surfaced boards. These dimensions may be varied to suit such orders as may be given, and embrace any width, length or thickness. Unlike lumber, however, narrower widths are the most costly. This straw lumber may be ripped with the hand-saw or upon the buzz-saw; may be run through the sticker for the manufacture of moldings, and takes a nail or screw about as well as oak. It may be finished with varnish or paint, and is susceptible of a high polish. It is water and practically fire proof, being manufactured under 500° of heat, and we are assured has been boiled for some hours without any apparent change of structure. Its tensile strength is greater than that of walnut or oak, and its weight about one-fifth greater than the former when dry. It is made from any kind of straw, including hemp and flax fiber—in fact, from any material that will make pulp—and a ton of straw will produce 1,000 ft. of boards. This pulp is rolled into thin sheets, a number of which, corresponding with the thickness of the lumber desired, are placed together with a peculiar cement which is claimed to be water proof, and are then rolled under a pressure sufficient to amalgamate them into a solid mass, which may be worked with a plane if desired.

“When it is remembered that it takes 100 years to grow a tree to maturity snitting it for commercial purposes, and a tree producing 32-inch lumber will require fully twice that time, while 20,000 ft. per acre is a large yield under the most favorable circumstances, it will at once be realized that where 2,000 ft. can be taken from an acre of ground for an indefinite number of years, the process which enables such a result to be accomplished and which will yield a really valuable lumber, is one of vast importance. We look for valuable results in the future in the manufacture of lumber from what is practically a waste material, but which will be produced in endless quantities so long as the United States maintains its character as a grain-producing country.”

The Art of Grinding Tools.

There seems to be a great number of workmen who pay not the slightest regard as to how a tool should be ground to do good service. A hasty examination of some of the tools, as they lie on the lathe board, will convince the intelligent workman of this fact, that many tools are carried to the grindstone to be ground, but from want of knowledge of the art of properly grinding the tool, are brought back unimproved, and one by one placed in the tool-post, ready to wrestle with the article to be operated upon, and the power which is struggling to overcome the combativeness of the tool. Now and then the belt slips from sheer exhaustion. How often this happens in the workshops need not be told to the mechanic who, often out of pure sympathy for the operator, now and then gives him a few points in grinding a tool, so that it will not require more than one-tenth the power to properly do the work. More than one-half of all the wear and tear and breakage, and bother of dull tools, comes from a lack of proper knowledge and practice in grinding. All steel, however highly refined, is composed of individual fibers, laid lengthwise in the bar, and held firmly together by cohesion. In almost all forms of cutting implements, the steel portion which forms the edge, is laid in and welded to the iron longitudinally, so that it is the side of the bundle of fibers, hammered and ground down, that forms the edge. Hence, by holding on the grindstone all edge tools, as axes, drawing-knives, knives of reapers, scythes, knives of straw cutters, or tools in general use by mechanics and workmen, in such a manner that the action of the stone is at right angles with the plane of the edge, or in plainer words, by holding the edge of the tool across the stone, the direction of the fibers will be changed so as to present the ends instead of the side, as the cutting edge. By grinding in this manner, a finer edge is set, the tool is ground in less time, holds an edge a great deal longer, and far less liable to nick out and break. A little practice in grinding, with a knowledge of what the tool has to do, will in due time reduce the number of ngly looking tools so often found in the workshop.—*E. E. Simonds, in American Machinist.*

Steam Room in Boilers.

A contributor to *London Engineering* writes as follows:—

“I wish to ask a sufficient explanation for the fact that locomotive boilers are every day working unsatisfactorily with about one-seventh of the proportion of steam room per indicated horse-power usually found in ordinary marine boilers. Taking a number of recent examples of marine boilers by first class makers, the proportion of steam room per actual indicated horse-power developed in continuous running at full speed, varies between the extremes of one-half and one cubic foot, or say a mean of .75 of a cubic foot. On the other hand, the locomotive boiler of a first class torpedo boat has fifty-seven cubic ft. of steam room, while the indicated horse-power is 450, which gives .127 cubic ft. per indicated horse-power, but about one-sixth of the previously mentioned proportion in marine boilers of ordinary construction. The boiler of a powerful goods engine belonging to one of our principal railway companies has 42 ft. of steam room, which, estimating the indicated horse-power developed at full speed at 500, gives .08 of a cubic foot per indicated horse-power, or one-ninth the proportion obtained in marine boilers. This difference is rendered more striking when it is remembered that at least 50% more steam per horse-power is drawn from the locomotive boiler with a simple high pressure engine than in the case of the marine boiler, with compound condensing engines. The assumption that the amount of steam room should be proportioned to the amount of steam drawn from the boiler in a unit of time, that is, to the indicated horse-power approximately, evidently is not applicable to all cases. To what, then, shall the amount of steam room be proportioned?”

This letter opens a question which can, with perfect propriety and the certainty of eliciting information, be discussed here as well as in England, for, while our practice is somewhat different, the natural laws remain the same.

Recasting Old Bearings.

This frequently becomes necessary in the practice of every wood-worker and should be done understandingly.

To remove the old metal: Take a narrow cold-chisel and cut a groove entirely through the middle of the old babbitt, longitudinally. Each half can then be removed easily and in one piece. Extract from the cap in the same manner. Clean the cavities thoroughly.

If the box is of the self-oiling pattern, wedge the opening of the oil-holes completely full of wood and projecting up enough to touch the shaft when the latter is in position.

Line up, packing the end of the boxes with card-board, that the shaft may not bear against iron at any point. Also pack about 1-16 inch of paste-board against the shaft, on each side, under the cap, which must be screwed down firmly. Use putty or stiff clay to stop all cracks.

The babbitt metal is ready for use when heated sufficiently to char a pine stick. When practicable, both sides of the bearing should be poured simultaneously, as there will be less danger of springing the shaft. Do not have the metal too hot, as the shrinkage will be in proportion to the temperature. Have everything perfectly dry, and a free gate for the escape of gases, if you would avoid explosion.

Remove cap, trim all edges rounding, and with proper tools open all oil holes. Finally, it is best, although not always essential, to scrape the bearing to a fit.

**SPECIAL KINDS OF CAST STEEL.**—A special steel for taps, called mild-centered cast steel, is made by converting a cogged ingot of very mild cast steel, so that the additional carbon only penetrates a short distance. These bars are afterwards hammered or rolled down to the size required, and have the advantage of possessing a hard surface without losing the toughness of the mild center. Another special steel, somewhat analogous to mild-centered cast steel, is produced by molting a hard steel on to a slab of iron or very mild steel heated hot enough to weld with the molten steel, so that a hard may be produced, one-half of which is iron and the other half steel, or three-fourths iron, and one-fourth steel, as may be required. A third kind of special steel, which is used for turning tools, for chilled rolls, magnets, and some other purposes, is made by adding a certain percentage of wolfram, or, as the metal is more generally called, tungsten, sometimes with and sometimes without carbon, sometimes to such an extent that it can be used without hardening in water. Special steel of this kind is the finest grained that can be produced, but it is so brittle that in the hands of any but exceptionally skilled workmen it is useless. The addition of chromium, instead of wolfram, has somewhat the same effect.—*Ironmonger.*

**AN INDUSTRIAL PROBLEM.**—One of the great industrial problems to be solved by the American people is how to adjust the relations of machinery and minutely divided labor, so as to secure on the one hand the best and cheapest productions, and on the other hand to counteract the tendency of specialization to narrow the scope and value of the workman's life. Our operatives are also citizens and sovereigns; and society cannot afford to spoil the citizen to save a fraction of a cent on a yard of cotton or a few dollars on the price of a ship or an engine.

SCIENTIFIC

PROGRESS.

The Importance of Science.

Mr. Quatrefores, in an address delivered some time since, at Bordeaux, before the French Society for the Advancement of Sciences, well observed: “All men cannot be expected to enlist under the banner of professional science. But all may and must acquire scientific notions, sufficient at least to understand the utility of the intervention of special men, and to be able to judge when that intervention becomes necessary. Science is nowadays omnipresent, and tends more and more to become the sovereign of the world. What industry is there that does not want the help of the engineers, and would remain content with the progress already accomplished? What branch of manufacturers would decline this help of chemistry? What medical practitioner, worthy of that name, would consent to forsake physiology, that complex science, the offspring of chemistry, and would do without natural philosophy, any more than anatomy? What intelligent agriculturist does not understand that the problems of culture and production are essentially questions belonging to zoology, botany, geology and chemistry? And in this great city, one of the queens of universal commerce, what merchant would deny the importance of geography?”

“Science is as indispensable to the military man as it is to the manufacturer, the medical practitioner, and the agriculturist. I am not going to undervalue the share that, in war, falls to inspiration and gallantry. But inspiration must be enlightened by study, and courage must be aided by weapons equal in efficiency and power to those of the enemy. No more than the agriculturist or the manufacturer, can the officer master all the sciences the help of which is necessary to his profession. He cannot be expected to solve by himself all the problems raised by his single art. It is essential that he should first ascertain those problems, and confidentially appeal to scientific men, pointing out to them the application he wants. Let us, therefore, stir up the intellect of all men. Surely, we may hope to bring to light many treasures which, for want of the opportunities which it will be our object to create, might remain buried in the darkness of ignorance.”

“You see, gentlemen, that our task will be fulfilled only when every man exercising any influence on his neighbor, or having any amount of leisure on his hands, shall have become an enlightened friend of science; when the least among laborers shall know what principles regulate the processes and the practice of his handicraft. This is enough to make you understand that our work is one of time. Most of us will not see its ultimate end, but we shall bequeath this noble task to our sons, as a sacred heirloom, and you may rest assured that it will be accomplished by them if not by us. Look at the results obtained in England by our eldest sister, the British Association. It is owing to its action that part of the population of England has undergone a transformation. The sons of fox-hunting squires are now geologists, philosophers, botanists, archaeologists, etc. It is a banker who presides over the Anthropological Institute, and a brewer who is at the head of the Astronomical Society. The British Association reckons its members by thousands, and all the principal towns dispute the honor of its visits. Let us, then, begin our work with confidence; let us spare no efforts, for none shall be in vain. We know now, that in the physical world there is no loss of power, no loss of matter. It is so, and even to a more absolute degree, in the moral world. Will is also a power, a power that increases and multiplies by transforming the minds of men, like a ferment. We have the will for good; let us resolutely apply it, and we shall develop the intellects and raise the hearts of men by the diffusion of learning.”

**SMOKE AND STEAM UNDER THE MICROSCOPE.** L. J. Bodaszewsky calls attention to the rapid oscillatory movements which are disclosed by the microscope in the smoke of burning paper, wood, cigars, etc., when concentrated sun or electric light is thrown upon them through a lens. The particles are of a spherical form, and they are continually darting against each other, so as to represent very strikingly the motion of gas molecules according to the kinetic theory. Similar movements are observed in the vapors of nitric, sulphuric and phosphoric acids, sulphur, ammonia, etc., when examined under the microscope by the light of a glowing platinum wire.—*Dingler's Journal.*

**WORMWOOD AS AN INSECT-PUCE.**—M. Poyrot having observed that the immense tracts of wormwood (sagebrush), upon the American plains are free from insects of every description, is experimenting with the plant as a preventive of phylloxera. He finds no difficulty in cultivating the wormwood, and he proposes to mix the stalks with manure, or simply bury them in the ground in the neighborhood of the vines. His suggestions have been sent to the Phylloxera Committee of the French Academy.

**MOLDING IRIIDIUM.**—Mr. John Holland, of Cincinnati, has discovered the process of fusing and molding iridium, which heretofore has been considered impossible. Phosphorus is the chief element.

Unrecognized Qualities in Charcoal.

Among the numerous and varied properties possessed by charcoal, says the *Scientific News*, there is one—one, too, of the most wonderful—which does not seem to be adequately recognized, probably from its being imperfectly known, except to physicists. It is that of being able to condense and store away in its pores many times its own bulk of certain gaseous bodies, which it retains, thus compressed in an otherwise unaltered condition, and from which they can be withdrawn, as required, as from a reservoir.

That eminent scientist, M. Saussure, undertook the task of a systematic examination of this subject, with a result which will prove surprising to the general reader. Operating with blocks of fine boxwood charcoal, freshly burnt, he found that by simply placing such blocks in contact with certain gases, they absorbed them in the following proportions:

	Volumes.
Ammonia.....	90
Hydrochloric acid gas.....	85
Sulphurous acid.....	65
Sulphureted hydrogen.....	65
Nitrous oxide (laughing gas).....	40
Carbonic acid.....	35
Carbonic oxide.....	9.42
Oxygen.....	9.25
Nitrogen.....	6.50
Carbureted hydrogen.....	5
Hydrogen.....	1.75

It is this enormous absorptive power that renders of so much value a comparatively slight sprinkling of charcoal over dead animal matter as a preventive of the escape of the odors arising from decomposition. A dead dog having been placed in a box in the warm laboratory of an eminent chemist, and covered with charcoal to the depth of between two or three inches, could not be discovered to have emitted any smell during several months, after which time an examination showed that nothing of the animal remained but the bones and a small portion of the skin. To the large excess of oxygen over the nitrogen in the atmosphere, which, according to the above table, was absorbed by the charcoal, and which thus rendered harmless the noxious vapors given off by the carcass as they were being absorbed, is doubtless owing to the fact above stated and the further fact of the charcoal never becoming saturated.

In a box or case containing one cubic foot of charcoal may be stored, without mechanical compression, a little over nine cubic feet of oxygen, representing a mechanical pressure of one hundred and twenty-six pounds to the square inch. From the store thus preserved the oxygen can be drawn by a small hand pump.

From the fact of the charcoal absorbing oxygen in so much greater proportion than nitrogen, we have here a means of utilizing its discriminative powers of selection in obtaining unlimited supplies of oxygen from the atmosphere, which contains nitrogen five times in excess of its oxygen, or 20%, whereas by the separating or selective powers of the charcoal the mixed gases capable of being extracted from it contain over 60% of oxygen. It only suffices to withdraw this now highly oxygenized air into another vessel of charcoal, by the further exposure to which the proportion of oxygen will be increased to a still greater extent. This indicates a most feasible means by which atmospheric air can be decomposed in such a way as to provide a cheap supply of oxygen.

One can not readily recognize the fact, which is nevertheless true, that the condensing power of charcoal, as applied to ammonia, is equal to what would be obtained by subjecting this gas to a pressure of nearly 1,260 pounds on the square inch.

**NEW SUBSTANCE IN THE ROOT OF THE COTTON PLANT.**—Mr. W. C. Staehle, an American chemist, has discovered a curious new product in the bark of the root of the cotton plant (*Gossypium herbaceum*). When the bark of this root is exhausted by alcohol of the specific gravity of 0.84, a dark, reddish-brown liquid is obtained, which when distilled to recover the spirit, leaves a resinous matter which amounts to 8% of the original weight of the bark. The new product thus obtained appears black and shining, but when pulverized takes the color of the cochineal. It dissolves in 14 parts of alcohol, 15 parts of chloroform, 23 parts of ether, and 122 parts of benzol. It dissolves also in caustic alkalies, and is precipitated from these solutions by acids. Hydrate of potash colors it green. Sulphuric acid dissolves it with a red brown color. Its other properties have not yet been examined.

**DR. SIEMENS** proposes a new gas for heating purposes on shipboard. Instead of heating the retorts by means of coke in ordinary furnaces, the raw material left in the retorts after the gas has been expelled, is subjected to the influence of volumes of steam. The steam being decomposed by the latent heat of the material, passes as gas of enormous caloric power around the retorts, and so acts as an active means for the distillation of gas for illuminating purposes.

**SATELLITE GEOLOGY.**—In presenting the Annual of the Bureau of Longitudes, M. Faye described, as usual, the improvements which have been introduced into the volume. The one which will probably attract the most general attention for its novelty is a notice by M. Faye himself upon the comparative geology of the moon and the earth, with illustrative plates,

**QUICKSILVER.**—The quicksilver market is very quiet, with but very little stock on hand, and 37 1/2 cents the best price offered. Since the first of May exports have amounted to 2,505 flasks, valued at \$73,615. The receipts of quicksilver in this city since the 1st of January, aggregate 20,108 flasks. As to quicksilver flasks, new ones are worth \$1.25 and old ones \$1.05.

At Cerro Gordo, Inyo, the Swansea Co. has been overhauling their slag pile at the old furnace on the lake, with astonishing results. Thousands of tons of rich, half-smelted ore and metal have been sorted out.

The Miners' mill property at Lookout, Inyo county, has been sold by Belshaw & Co. to an Arizona company. It is to be removed to a point near Grapevine, on the Mohave river.

The Arizona Journal says that from the 19th to the 21st inst., inclusive, the product of the Copper Queen smelter was 31,257 lbs. of copper.

## The Mining Share Market.

Prices are rather high in the stock market just at present, though, as far as we know, there is no special occasion for it. Some say that the "bonanza crowd" are trying to make a deal through other people's agency. The Virginia Enterprise contains the following account of operations in the leading Comstock mines: "Next week the crosscut will be started up in the Sierra Nevada, and this will soon be followed by the completion of the snmp of the Union shaft and the beginning of operations at the 2700 level.

"At the California and Consolidated Virginia, they are now ready to begin prospecting a block of ground reaching up from the 2500 to the 2000 level; indeed, prospecting has already been commenced in a drift that is being run north from No. 1 winze at a depth of 30 ft. below the 2000 level. This drift is following a body of quartz that appears to be making northward. Next week the Gould & Curry and Best & Belcher shaft will again be going down into the very promising ground into which it was just entering when sinking was discontinued to rearrange the pumping apparatus, preparatory to pumping into the

40 ft on the Iron Silver mine at Silver Lake.

## The Placer County Iron Mine.

### A Flourishing New Industry.

We take the following from the Grass Valley Union:

For the past year there has been occasional reference in the press to the operations of a San Francisco company that was engaged in the erection of works and the building of charcoal kilns for the smelting ores found between Bear river and Clipper Gap, in Placer county. The works reached completion and the smelting of ore was commenced a few weeks ago, since which time there has been a regular and uninterrupted daily production of iron bars or "pig metal." From the fact that an important part of the company's operations are conducted on the Nevada as well as the Placer side of the river the enterprise is one of great interest to the citizens of both counties, and this was sufficient inducement for a representative of the Union to make a visit to the different works of the company a few days since, for which he feels that he was fully compensated in witnessing the magnitude as well as the novelty of the structures connected with this enterprise.

#### The Iron Ore.

The existence of iron ore at this point, where the furnace has been erected (4 miles from Clipper Gap and 6 from Auburn), has long been known, as the writer hereof was on the ground twenty years ago, when at that time a location of 160 acres of the land had been made for the purpose of establishing a claim to the ore, which was found at different points on that tract. The then owner realized that at some day the ore could be utilized, although then and for many subsequent years it has been valueless. About that time some of the ore was taken to Sacramento and smelted in the cupola furnace of Goss & Lanher's foundry, which showed as high as 85% of metal. Some of it was so pure that it could be beaten on an anvil. Subsequently, several other 160 acre locations were made, and the ownership passed to Messrs. Applegate, Brown & Myres, of Placer county. Various efforts were made subsequent to the construction of the Central Pacific Railroad Company to induce that Company and other parties to establish a smelting furnace on the land, but until the property passed to the present ownership, which consists principally or entirely of Messrs. E. Judson, A. P. Hotelling and Irving M. Scott, of San Francisco, nothing was done that took a definite and practical shape. These gentlemen being satisfied as to the quality and extent of the iron ore obtained title to the land and commenced active operations about one year ago. As the ore was of the kind known as "magnetic," charcoal was the desirable fuel to be used in its reduction, and about the first movement was to secure a large amount of wood land and to build

#### Patent Charcoal Kilns

To secure a supply of fuel by the time the furnace could be erected. The kilns were to be of brick, and brick sufficient for twenty kilns was burned in the vicinity, and the kilns were constructed during last season. Six of these kilns are near the river on the Placer county side and fourteen on the Nevada county side, in the southern portion of Grass Valley township. Of the fourteen kilns on this side of the river eight are on the Sales ranch, and six two miles below, both locations being in a section of country that furnishes a large amount of timber of the kind usually found in the foothills, black and white oak and nut pine. The kilns are built in dome shape terminating at the top in a sharp peak. Near the top of each is a wide door, in which to receive the wood for burning, and on the opposite side, at the bottom, is a door of similar size from which to draw the coal when burned. The kilns are built in a row, each standing close to the other, and an elevated roadway is built with lumber on a level with the upper openings of the kilns upon which the wood wagons drive to discharge their loads. On a level with the lower doors of the kilns another wooden platform is constructed upon which the coal is drawn out, and up to which the coal wagons drive and are conveniently loaded. Each kiln holds 40 cords of wood, and in filling them the wood is laid in carefully. The wood is cut in cordwood lengths, and is put in from small limbs to logs two ft. in thickness. It takes 15 days in all to burn a kiln of coal, 5 days to put in the wood, and 5 to cool. Each kiln has a capacity of 2,500 bushels. The company owns the kilns and the wood, but the coal is burned under contract by Messrs. Eghert, Hayford & Co., of Colfax, who have established camps at each set of kilns, but make their principal one at Bear river, where they have established a store and have their principal stables for coal teams. They employ about 175 coal burners, woodchoppers and teamsters, and conduct the entire business of making and delivering the coal at the furnace, which enables the Iron Company to greatly simplify their business, and gives them no care except in the direct running of the smelter and the extraction of ore. The charcoal is delivered at the furnace at the rate of 8 cents per bushel. In going to the iron mine from this direction the charcoal kilns are first visited, and an idea obtained as to the magnitude of the whole enterprise in seeing the destruction that is being made of the timber, the big piles of coal ready for hauling, the men and teams employed, and

the great white domes of the kilns, which at first sight are a cause for surprise and curiosity. From the kilns on Bear river to the

#### Furnace

Is 2½ miles, which on approaching is discovered to be a combination of buildings, the tallest of which is about 50 ft. in height, and surrounds the stack or furnace. The actual height of the furnace proper is 47 ft., built of fire-proof brick and having an outside sheathing of heavy boiler iron. In this same building is the casting room, where the molten metal is cast into bars when run from the furnace. In one of the adjoining buildings is located two hydraulic elevators, by which the ore and charcoal is raised to the top of the furnace, and a rock breaker for reducing the ore to the proper fineness for the furnace. Another building contains the powerful engine which drives the blower for a hot-air blast, and a small engine that runs the rock-breaker. Alongside of the engine house is a brick structure which serves a novel purpose in the utilizing of the gas that is generated in the stack from the charcoal used in fusing the ores. This gas is conveyed by a large conductor leading down from near the top of the stack to a large gas receiver which is set alongside of the brick structure spoken of. From the receiver the gas passes into the furnace under the steam boilers and gives all the necessary heat to make the steam which runs all the machinery—no other fuel being used. The large pipe carrying cool atmospheric air from the blower passes through the brick structure which is filled with pipes heated with the gas, so that when the air reaches the bottom of the furnace, into which it is discharged at four different points, it is a powerful hot-air blast that constantly and strongly fans the flame in the furnace. This utilizing of the gas is very interesting as well as a novelty in iron manufacture, the adaptation being, we understand, but recent—in fact, there have been but five furnaces constructed on the plan of this, which represents the very latest improvements. All the machinery and the structures about the furnace are of the most substantial character, and look as if neither care nor money had been withheld in providing them. In feeding the furnace a charge of 800 pounds of iron ore which contains 25 pounds of marble rock for a flux, is put in at this top. This ore is raised up on the elevators in an iron barrow. After the ore a charge of 30 bushels of charcoal is put in, which is received in the same manner. These different charges are put in about 20 minutes apart, and thus the work goes on continuously, there being no cessation, as once the furnace is in blast it must be kept so unless every particle of its contents is drawn off. The furnace has a capacity for the manufacture of 40 tons of iron in 24 hours, but its present product is 25 tons, as the facilities for burning charcoal are not yet up to this full standard. The casting of the pigs is made twice a day. Up to the present time about 750 tons of metal have been cast, of which about 400 tons are awaiting shipment from the furnace. The iron made is rated No. 1, 2, and so on, according to appearance the workmen understand, but it is all good, and the high grades are said to be the best iron in the market, and will bring several dollars per ton more than the best Eastern or imported iron in the market.

#### The Iron Ore

Is found on the hillside, not more than 200 yards distant from the furnace, and so far as extracted, has been taken out from open cuts. The ore is of high grade, reaching over 80%, and has a short distance beyond hematite ore has been found that will reach 90%. In close proximity to this is a strong vein of marble, which makes a fine flux for the ore, otherwise, that or limestone would have to be procured elsewhere. Ore has been found on other portions of the tract, so that the company feel warranted in believing that the supply is inexhaustible.

The employees about the furnace number 80 white men (no Chinese are employed) whose average pay is \$2.50 per diem. The men work eight-hour shifts, with the exception of the miners, who work ten-hour shifts.

#### The new Town.

A short distance from the furnace, and safely away from its heat and dust, is the embryo town, which consists of a large hoarding and five or six neat houses, built on the opposite sides of a wide street. The location is well chosen, as the site is smooth, and the natural growth of the forest trees give it a cool and homelike air. The town has had no christening yet, and is included in the general name of the neighboring improvements, "The Iron Mine."

#### A Great Enterprise.

A visitor can not but be struck with the importance of the enterprise, its evident cost, and the promise it gives of the permanent establishment of an industry right here in the foothills that is full of promising value to the surrounding country. It is wholly unlike gold-mining, and seems rather out of place down among the grass and wood ranches, but it looks as if it was a business enterprise in which the owners had no idea of failure. It is the only thing of the kind in the State, and a visit to it will compensate any one for the trouble, however far they might have to travel.

James M. White, of Rochester, New York, an experienced and skillful iron manufacturer, is general manager of the furnace and works, whose assistant in the clerical duties is Mr. E. W. Cowles, of San Francisco.

## Auriferous Slate Deposits of the Southern Mining Region.

[Read by P. H. MELL, JR., M. E., of Auburn, Ala., before the American Institute of Mining Engineers.]

Can the auriferous slate deposits of the Southern mining region ever be successfully worked? is a question that has been often asked me by persons seeking investments in Southern mines. As the subject is one that has given me much thought during the past few years, I have decided to present my conclusions to the members of the institute for their consideration. Those who have had the opportunity of exploring the region mentioned above, will readily recall to mind numerous localities to which their attention was directed by would-be miners as "rich and desirable properties," in which there were but few quartz seams running in every direction through fine-grained talcose slate. Most of the gold in such formations was always found disseminated through the slate, and but a small percentage contained in the quartz. Such are the deposits I propose to discuss in this paper.

Of course there are many excellent quartz mines in the South that are paying the owners good profits, and many more to my knowledge that are not being worked for obvious reasons. But it is out of the question to suppose that these slate deposits can be practically worked by the same methods adopted for extracting the ore from well-defined and prominent quartz veins. It is true that in many instances these slate formations are quite rich in gold, but this is not uniformly the case, and as there is no chance of sorting the ore, handling so much crude and dead stuff in the ordinary way of mining and milling would be ruinous.

It has been my privilege to examine quite a large number of these formations in the South, and, as a general thing, they were found so thoroughly decomposed as to render it not at all difficult to spade the slates, and pulverize the whole mass between the fingers. These formations are sometimes several hundred feet in width, extending to unknown depth, and varying in length from a few hundred feet to several miles. In fact, in every respect, except as to composition and location, they bear a striking resemblance to the ordinary gravel deposit.

Now, why cannot these slate formations be worked by water, somewhat in the same way as ore is concentrated in gravel beds? This plan has, in part, been adopted by N. H. Hand & Co., in working a property located near the Pigeon Roost region, Lumpkin county, Ga. The idea seems to have suggested itself to these enterprising men from the surrounding circumstances. It is well known that for a number of years this company have been supplying their mines with water from a well-constructed ditch over 26 miles in length, and by means of this ready agent they have successfully worked the slate vein mentioned above. Before N. H. Hand & Co. took possession, the property was very thoroughly tasted by the old plan of driving shafts and extracting the ore by means of picks and shovels. Very expensive and elaborate machinery was employed, but without success, and the property was eventually abandoned with considerable loss to the company. When the present owners, therefore, took possession, the past history of the mine contained but little to encourage them in this prosecution of the enterprise. There was no regularly defined vein of quartz, but simply a large mass of fine-grained talcose slate, throughout the length and breadth of which good pannings of gold were obtained. A 25-stamp battery, run by water, was erected one-half mile from the mine, at the lowest point accessible. On a high hill in the neighborhood of this mine a large reservoir was supplied with water from the ditch mentioned above, and by means of a "little giant," in connection with this reservoir, playing under a pressure of 150 ft. head, the vein of decomposed slate and quartz was driven through rifle boxes towards the mill.

The inclination of these boxes was sufficient to carry everything in the nature of ore into the mill-house, and the force of the water being broken there by mechanical means, only the finely pulverized slate and floating mud were permitted to pass away and settle wherever opportunities were presented in the various gulches. It was of course necessary at times to break up by means of hammers, or otherwise, any large boulders that were washed down from the vein before permitting them to enter the rifle boxes. But these were of such rare occurrence that two to four men were all that were necessary to supply the mill with ore. The net profits yielded by this mine per week in 1879, under the above treatment, were \$300.

The unused water power of the Southern gold belt is immense, and if companies could be formed to build the proper water ditches to reach these present worthless properties, there would be a wonderful revolution and revival in the mining interests.

From the geological reports of Georgia I find that there are 180 prominent streams in the gold belt of that State, that furnish in the aggregate 26,000 cubic ft. of water per second, the capacity of each stream varying from 2 cubic ft. upward as high as 3,000 cubic ft. per second. This amount of water would give, with an assumed head of 100 ft., 285,640 theoretical horse-power, or 190,426 available horse-power. Again, 26,000 cubic ft. per second would be equivalent to 1,560,000 cubic ft. per minute, and this volume of water confined in a

ditch would supply about 700,000 miners' inches. North Carolina and Alabama are not behind Georgia in the supply of water, and the most of this vast power is running unused to this sea. Prof. Kerr, State Geologist of North Carolina, has given in his report a full and interesting description of the valuable streams of his State, and in some instances gives the estimated water powers. It would be interesting to read this report in connection with this article.

Custom mills should be built at intervals throughout the region, and this water utilized for not only washing down and concentrating the ore, but also transporting it, if possible, to the mill ready for crushing and amalgamating. Upon actual experiment in Georgia, it has been found that by such treatment ore can be profitably handled that yields but 75 cents per ton. Last year the manager of the Findlay informed me that where the ore could be reached by the water, he had succeeded in mining and crushing at a cost of but 28 cents per ton. This was the case, however, where the water was made not only the mining but the transporting agent as well.

The climate is delightful the year round, and seldom are the streams so locked up with ice as to suspend all mining operations. Railroads are running within a few miles of the farthest point of the mining region. Provisions are cheap, and in great abundance. Labor is to be had in sufficient amount, ranging in value from 50 cents per day for ordinary hands to \$1.50 per day for mechanics. The forests are also in their original beauty and abundance, and there is, of course, no lack of wood for building and fuel purposes. So, in summing up, it would not be far from right to assert that, with all these advantages, the same class of ore that is now cast aside as worthless on the Rocky mountain slopes, could be profitably worked in North Carolina, Georgia and Alabama.

## Note on a Direct Process for Treating Fine Iron Ores.

[Read by W. E. C. EUSTICE before the American Institute of Mining Engineers, Subject to Revision.]

This may not be entitled to the credit, or discredit, of being a direct process; still as nothing but iron is reduced to the metallic state, I think it may be called direct.

Interesting experiments have been carried out with the following process at the copper smelting works of the Orford Nickel and Copper Co., Capelton, P. Q., Canada:

1st. The fine iron ore is mixed with a sufficient proportion of fine coking coal, and is coked in any of the ordinary methods for making coke. The effect of this is to convert the iron oxide into sponges in such a shape that the usual trouble of oxidation is avoided.

2d. The resulting mixture of coke and sponges is melted down in an ordinary cupola, the coke furnishing more than sufficient fuel for that purpose.

I may briefly point out here that in the first place the iron is sponged, and this, as is well known, contains no phosphorus or silicon when the reduction takes place at a low temperature; and in the second place, this sponge is melted down in a cupola in which there is no zone of reduction for phosphorus or silicon, and that consequently the resulting iron should be free from both of these impurities.

3d. The liquid sponges, now carburized, is run into an open-hearth furnace, where the requisites degree of hardness or softness is obtained by adding some of the fine ore, and the usual dose of ferromanganese.

I have merely given above this rough outline of the process, but it is my intention, as early as possible, to bring the process more fully before the Institute.

SMELTING ORES.—Many persons, with a thorough knowledge of mines and mining prefer a mine whose ores are of such character that the greater percentage of the valuable minerals which they contain can be obtained by smelting. To all such the Candelaria True Process can say that the State Line mining district is the place for them to seek for such mines. This district joins Columbus district on the south and extends from its southerly boundary to the line of California, hence its name. It was organized in 1874, and though but little work has been done on the mines, that little shows large deposits of valuable ore, which is pronounced as the very best for smelting purposes, containing all the natural fluxes. William Groezinger, of Columbus, has some locations in the State Line district, from which considerable good ore has been extracted. He says there is plenty of wood and water and the ledges are high and strong. Such specimens as are in his possession at Columbus are principally of cube galena and are as perfect and well-cut cubes as though artificially made. At the lower end of Fish Lake valley is also found large quantities of smelting ore which with the advent of the railroad will certainly be very valuable.

A MOUNTAIN OF MARBLE.—It is reported that the marble mountain down in Table Mountain District has been located, and that the quality of the marble is not excelled in the United States. It is said to be worth \$3 per cubic foot in San Francisco. If such is the fact, the quarries will be worth as much as a rich silver mine, as the supply is inexhaustible. Old prospectors have known of the existence of this marble mountain for years; but, as they were looking for silver mines, they did not consider it of sufficient value to bother with it.—Silver State.

## Plants Worth Trying in California.

[The following is the second branch of the report on plants worth trying in California, (based upon Baron Von Mueller's select plants) made to the State Horticultural Society, at the May meeting, by H. Bohr and W. G. Klee.]

**Cassia acutifolia**—The leaflets of this species furnish part of the Alexandria Senna. It is a perennial plant, much of the same habit as the Maryland Senna, and might easily be protected from frost if not quite hardy. *Cassia fistulosa* is perhaps a hardier species. It is the pods of this that are utilized; besides its usefulness, it would be another very ornamental tree added to our gardens.

**Cinchona Calisaya**—The source of the yellow or Calisaya bark, and also of part of the Crown bark, is found in Peru, New Granada and Bolivia at an altitude of 5,000 to 6,000 ft. The tree attains a height of 40 ft. There appear to be many varieties of this species; a Santa Fe variety ascends to 10,000 ft. elevation. *C. Calisaya* has been and is being tried yet at the experimental gardens of Berkeley. Specimens which escaped the early November frosts at as low a temperature as 28° F. were killed afterward by this moist cold which never was actually as cold by measurement as previously. Seeds of these were from Indian plantations where this species thrives, but it would be very desirable to obtain the hardier varieties, as, for instance, the Santa Fe variety. Vilmorin-Andrieux, of Paris, has seeds for sale of various cinchonas, among them Calisaya, var. *anglica*, which is supposed to be from India, and Calisaya, var. *Javanica*. The price is very reasonable, 6 francs for 10 grammes of good seed.

**Cinchona nitida**—The source of the grey or Huancabo bark, is one of the largest growing of the Peruvian bark trees, reaching under favorable circumstances the height of 80 ft., judging from the locality (high elevation of the Andes in Peru and Ecuador). Von Mueller thinks this species one of the hardiest; we are not aware of this species having been tried in California.

**Cinchona officinalis**—Andes of Peru, and New Granada, at an elevation from 600 to 10,000 ft.; yields the Crown or Brown Peru bark, besides part of Loxa bark. This species is averse to a superabundance of moisture, and among its several varieties there will probably be found the hardiest of all cinchonas, the *Crispilla* variety; it is said to endure an occasional frost as low as 27°. The *Officinalis*, and what perhaps is the same, *Condaminea*, have both been grown from seeds in Berkeley. Like the Calisaya, they resisted the early frost of November and lived through the winter by a slight protection, but a decay of the stem set in late in the spring after they had commenced to start which they never recovered from.

The *Cinchona lancifolia*, by Weddell—Considered a variety of *Officinalis*, grows in places where the mean annual temperature is that of Rome, with, however, less extremes of heat and cold. Seeds of *lancifolia* may also be obtained of Vilmorin-Andrieux, in Paris. Seeds from this source are now sprouting at propagation houses of the experimental grounds in Berkeley.

**Cinchona pitayensis**—Is another variety that in upper India has brought some of the best results. It is a tree 60 ft. high. Still another kind, *Cinchona Hasskarliana*, may perhaps belong under *Officinalis*, though the seeds are very much smaller—at least such is the case with samples of this kind procured from Vilmorin. This species has in Java proved very valuable, and deserves like the rest a thorough trial.

**Cinchona succirubra**—From the Middle Andine region of Peru and Ecuador, is a tree attaining a height of 40 ft.; the source of red Peruvian bark. This species has in Berkeley borne out its reputation of being one of the hardiest of bark trees, being the only one of four species that has successfully survived the winter by a very slight protection, and it will probably be this kind that will be found to be the most paying here, as it seems to have been in other countries.

**Camphora officinarum**, or *Cinnamomum camphora*, Lauraceae—The camphor laurel of China and Japan is one of the most beautiful of evergreens, the varied colored hue of the foliage from purple to light green contrasting finely with yellowish branches. Apart from that it may become of great value as the source of camphor. It should be planted in the garden, park and promenades as a shade tree of peculiar beauty. It will most probably be found to be perfectly hardy in all the valleys of California, as it has been tried with success in various parts of the State. In Berkeley it has proved a fast grower; and the young foliage would seem even to be untouched by severe frosts. It is on the whole a tree that cannot be recommended too highly.

**Colubium officinale**—In the northern part of this State, where moist meadows occur, this pretty perennial herb would flourish, and might be sold with profit to the drugstores.

**Ilex Paraguensis**—The Paraguay tea, or mate. The leaves of this bush, which is a holly, are used as a tea by millions of people in Uruguay, Paraguay, and many other countries throughout South America. Though it perhaps never would find much favor with people accustomed to tea, it deserves cultivation trial, as the source of a highly stimulating product. Its nativity places it among the doubtful plants as regards hardiness.

**Forma galbaniflora**—Another umbelliferous plant to be recommended for mountainous regions. It is a perennial, yielding the gum resin galbaunum.

## USEFUL INFORMATION.

## Don'ts for the Varnish Room.

The *Coach Painter* comprises a large store of valuable advice in the following brief article:

Don't use the bucket for a washbasin, or the "shammy" for a towel.

Don't touch your work with sweaty hands.

Don't flood your floor with water; have it clean and dry every time.

Don't wash off your work in the same room you finish it in.

Don't fail to use plenty of clear, soft water in washing off, for if the work won't stand a thorough washing, you understand why, and will not look for a lasting job.

Don't apply your finishing coat, or any other, until you have completely cleaned your work, and are sure it is perfectly hard and free from moisture.

Don't let the pumice in corners, and around and under the moldings, escape your notice.

Don't apply a cold varnish on a warm job, or a warm varnish on a cold one.

Don't keep your varnish in a damp or cold place.

Don't overload your work by laying two coats in one. A full coat laid on evenly is all-sufficient, and will give you a finer looking and more durable job.

Don't work your varnish too long, or leave it too soon. Become acquainted with it and it will obey you first and last.

Don't say you haven't got a good, dry, tight, clean, clear, high-studded and well-ventilated varnish room—*don't*.

Don't pour your varnish back into the can taken from; it will cause you trouble. Have a clean can for the purpose, and use it only after time is given to settle.

Don't keep your brushes in oil or turpentine; keep them in the varnish you use them for.

Don't use any but the best rubbing varnish (it is the cheapest in the end), and follow it with the best finishing.

Don't you know that a job turned out with a fine finishing varnish over a poor rubbing—although it may please you for the time being—will soon return to you for repainting and re-varnishing?

Don't attempt to be a varnish maker by diluting your stock with oil or turps; don't meddle with it, but, if unsatisfactory, send it back to the maker, explaining the trouble.

Don't always lay the blame of a bad job on varnish, brushes, weather, and many other things; but look at home—*once*.

**FINE LUBRICATING OIL.**—Put fine olive oil in a bottle with scrapings of lead and expose it to the sun for a few weeks. Pour off the clear oil for use. Another method is to freeze fine olive oil, strain out the liquid portion and preserve for use. Another good lubricating oil, especially for clock and other delicate machinery is made as follows: Take olive oil and dissolve it in boiling alcohol, and add it drop by drop until it is no longer taken into solution. Upon cooling it will let fall crystals and leave a considerable portion still fluid. The fluid part is to be poured off, filtered through a piece of white blotting paper, and may be used in this form, or the alcohol may be distilled off for fresh processes, and the pure lubricating oil which remains is very suitable for oiling watches, clocks or other delicate machinery. This will not oxidize or gum up, even when exposed to great cold. Or take neatfoot oil and drop it into some lead shavings, in order to neutralize the acid contained in the oil. Let it stand for a considerable time, the longer the better. Oil thus prepared never corrodes or thickens.

**CURE FOR WARTS.**—A correspondent of the *Scientific American* writes as follows: Some years since a corn doctor advised me to use coal oil. My hands were covered with them. Having little faith I tried it, putting a drop on each of common kerosene and letting it absorb; where there was a hard crust, scraping it to facilitate absorption. In a fortnight after twice daily treating them, they began to lessen, and finally disappeared without scar. Then the right hand, in part, leaving one which remained after all others had passed away, and then that one. Have advised others to try it, with like effect on persistent use. Simply softened the top, dropped the oil on, and let it be for some minutes to absorb.

**THE LARGEST STEEL CASTING.**—Messrs. W. Jessup & Sons, of Sheffield, lately made the largest crucible steel casting of which we have any record. It was a spur rim 23 ft. in diameter, machine molded, and was cast whole. The total weight of the casting was 10 tons. The rim is intended for the cotton mill of Mr. Smallpage, Barnley. The steel wheels are expected to pioneer a new branch of industry in the Sheffield trades.

A DIAMOND EXPERT, of Chicago, asserts that many of the so-called solitaires, sold as single stones, are made up of small stones cleverly put together. Under the blowpipe they separate. He adds the surprising statement that not one diamond in ten, sold in this country, is other than the refuse London market. Nearly all are off-colored, specked or feathered, and are sold at a fictitious value.

## Oilstone and Oilstone Powder.

The Turkey oilstone can hardly be considered as a home slate, having nothing of a lamellar or schistose appearance. As a whetstone it surpasses every other known substance, and possesses, in an eminent degree, the property of abraded the hardest steel, and is, at the same time, of so compact and close a nature as to resist the pressure necessary for sharpening a graver or other small instrument of that description. Little more is known of its natural history than that it is found in the interior of Asia Minor, and brought down to Smyrna for sale. The white and black varieties of Turkey oilstone differ but little in their general characters; the black is, however, somewhat harder, and is imported in larger pieces than the white.

Fragments of oilstone, when pulverized, sifted and washed, are much in request by mechanics. This abrasive is generally preferred for grinding together those fittings of mathematical instruments and machinery, which are made wholly or in part of brass or gun metal, for oilstone, being softer and more pulverulent than emery, is less liable to become embossed in the metal than emery, which latter is then apt continually to grind, and ultimately to damage the accuracy of the fittings of brass works. In modern practice it is usual, however, as far as possible, to discard the grinding together of surfaces, with the view of producing accuracy of form, or precision of contact.

Oilstone powder is preferred to pumice-stone powder for polishing superior brass works, and it is also used by the watch-maker on rubbers of pewter in polishing steel.—*Workshop Companion*.

## GOOD HEALTH.

## Treatment of Carbuncle by Carbolic Acid.

In the *Toledo Medical and Surgical Journal*, December, 1880, Dr. J. T. Woods writes:

It is now about two and a half years since a patient presented with two carbuncles, one on the back of the head, the other below it, on the neck. They were of moderate size only, the upper one open in three places, while in the lowest the skin was unbroken.

Having considered the various known properties of the carbolic acid, I determined to use it vigorously instead of inserting it in meager quantity. I loaded my hypodermic syringe, and passing the point through the openings and into the sloughing mass in every direction, I completely saturated it with the pure acid and awaited results. In a minute the smarting disappeared, and with it all pain and all sense of soreness.

By this result emboldened, I again charged my instrument, and thrusting it through the skin over the other carbuncle, in a variety of places, I soaked the whole carbunculous mass beneath the skin, enough of necessity escaping to fully bathe the borders, modify inflammation and destroy any septic elements then developed. I waited, not without concern, and was delighted to learn in a few moments that all the pain and soreness was gone in this also. The skin over the mass became quickly white, hard and dead, and in a few days detached, in the form of a slough, the interior mass also becoming rapidly loosened, only requiring the cutting of a few shreds to remove it, when the cavity was found to present a satisfactory appearance and rapidly filled up, leaving an exceedingly small cicatrice. The remarkable feature in this case was that after the complete saturation of the carbunculous mass no pain occurred, my patient going about his ordinary labor without discomfort. It is now one year since I treated a very painful case, the same method bringing about similar results, the party suffering no pain or even soreness after the lapse of one minute following the injection.

I would advise the use of the pure acid only, and to complete saturation. Dilution would increase, if not create, danger of absorption of the acid, converting a very simple procedure into a condition of great danger, and insufficient quantity defeat the purpose for which it is used.

**TRICHINOSIS.**—According to a recent report to the Sanitary Committee of Massachusetts, it appears that of 2,701 pigs examined during five months, no less than 154, or nearly 6%, contained trichinae. The animals came from different and distant regions, but the majority were from the Western States. The same report affirms that rats are affected with trichinosis at Boston to a much larger extent than in Germany. Of 51 rats caught in a Boston slaughter-house, 30 presented trichinae. On the other hand, 23 fowls fed in the establishment were found to be healthy. Forty rats taken in another large slaughter-house all contained trichinae, but of 60 found in different stables only six were thus affected. In France little consideration has, until lately, been given to the danger of trichinosis in imported pork. At Lyons, however, inspection has been commenced, and has quickly borne fruit. An enormous consignment of lard, amounting, it is said, to 120 tons, was lately received at Lyons from New York. Of 50 specimens examined immediately after arrival, three were found to be infested with trichinae. At Barcelona six cases of death from trichinosis have occurred in three months.

## Cancer.

Many persons undergo a good deal of mental suffering from the want of knowledge of one important fact in relation to this dreadful disease. It is this: When cancer commences, its march is steadily onward toward death, unless arrested; therefore any sore or tumor, however suspicious in appearance, which gets better, or which can be arrested by simple remedies, so that it improves or heals, is not cancer.

I do not say that such sores may not eventually become cancerous, where a tendency to the disease exists, and their liability to do so would probably be a little greater, as disease usually attacks the weaker points; but I do say that a sore that shows marked improvement from its worst condition should cause but little uneasiness or worry. It seems very difficult to determine with anything like certainty whether cancer is, or is not, an hereditary disease. Physicians are divided in opinion, just as they are in regard to the nature of the disease.

I have seen very many cases, and in all stages of development; and I am inclined to believe that the tendency to cancer is inherited—not that the disease exists as a blood poison, but that certain particles or nuclei exist by inheritance, which are liable under certain conditions to develop into cancer. I believe, moreover, that the prospect of eradicating the disease depends on its location, and upon the promptness with which the proper remedies are employed. If deep-seated, they had better be left to themselves, and efforts made to keep up the general health. If superficial, it is possible to destroy them effectually, in many cases, because they exist at first as local affections, the blood remaining for some time uncontaminated.

There resides in New York to-day, a physician, who twenty years ago lost the entire under lip by cancer. He says he arrested the disease by applying tannin to the sore every day and, on the day following, standing in front of a looking-glass, he could see small black spots in the sore; these were the upper extremities of the roots of the tumor, and, seizing them with a small pair of forceps, he would draw them out. He extracted very many in this way; in fact, all that existed. Many of these had preserved between plates of glass and showed them to me. They were from one to two inches long, and resembled the rootlets of a plant. In *Hall's Journal of Health* for December, 1877, I gave the history of a case of undoubted cancer that was cured by electricity. The patient was a most intimate friend, and my anxiety was great, for not a symptom was wanting on which to rest a doubt as to the true nature of the disease; it had extended rapidly to the ulcerative period, and seemed to me an almost hopeless case. My associate physician took a different view of the case, and it proved to be the correct one.

His theory was that cancer was at first a local affection, an independent and forcible body, and that the system does not become contaminated until ulceration has extended far enough for the matter to be absorbed into the system; that strong currents of electricity passed through the tumor would kill it, and that in a few days it would shrivel up and become detached from its seat, leaving the wound in a healthy condition. Such proved to be the case. In five weeks from the first application of electricity no sign was to be seen that any sore had ever existed, and the patient has been in the enjoyment of his usual good health ever since.—*Cor. Hall's Journal of Health*.

## Important to Bread Eaters.

The *London Court Journal* states that the letter to which the following article, from the *Huddersfield Journal*, refers, caused every bakery in London to be besieged: "We last week published a letter from 'Chemist,' on the advisability of the more general consumption of 'wheat-meal' bread. The question is one of great importance, and demands serious consideration. Wheat-meal bread is made from grain which has been deprived of only the outer covering, that is to say, the flour contains the bran. The bread thus produced is not only much cheaper than the ordinary white bread, but it is much better. A shilling's worth contains three times more flesh-giving material, 70 times more heat-producing material, and three times more bone-forming material than is to be found in a shilling's worth of beefsteak. For the discoveries in this respect we are indebted to the late Baron Leibig, who has done more than anybody else to show the world the secret of economical and wholesome cooking. Of course, it is not proposed that the highly nutritious wheat-meal bread should be man's only food. In Spain, it is true, the peasant lives and flourishes on wheat-meal bread and garlic, but the British working man would be very loth to go without the roast beef of old England. There can be no reason, however, why wheat-meal bread should not be substituted for ordinary white bread. By its nutritive qualities men would need less quantities of other victuals, and thus an appreciable saving of money would be the result, while (in growing children especially) the bones, sinews and muscles would be strengthened, and thick coats of pure enamel would preserve the teeth from decay. The only obstacle in the way of the adoption of wheat-meal bread is prejudice."

## TABLE OF CONTENTS.

GENERAL EDITORIALS.—Quicksilver Feeder for Gold Mills; Low Grade Ores; A Needed Cable Connection; Mining Titles in Alaska, 353. Passing Events; Color of Minerals; Miners and Mine Products; Taking up Coal Lands; A Smelting Oven; Mill Sites; Deep Mines in Idaho; Large Grant of Mineral Lands, 360. Notes of a Trip to Yosemite; A Portable Mining Flume, 361. Patents and Inventions; Notices of Recent Patents; Alaska Mines; Botany in Southern California; New Mexico, 364.

ILLUSTRATIONS.—Du Bois' Automatic Quicksilver Feeder, 353. Cathedral Peak Group, of the High Sierras, Beyond the Yosemite Valley, 361.

MISCELLANEOUS.—Copper Smelting—Its History and Processes—No. 8; Means of Desulphurization of Ores; The Sweetwater Mines; Our Scenery as One of Our Resources, 354. The Placer County Iron Mine; Auriferous Slate Deposits of the Southern Mining Region; Note on a Direct Process for Treating Fine Iron Ores, 358. Plants Worth Trying in California, 359.

MECHANICAL PROGRESS.—Straw Lumber—The Economy; The Art of Grinding Tools; Steam Room in Boilers; Reconstituting Old Bearings; Special Kinds of Cast Steel, 355.

SCIENTIFIC PROGRESS.—The Importance of Science; Unrecognized Qualities in Charcoal; New Substance in the Root of the Cotton Plant, 355.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments, Meetings and Dividends, 356.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Idaho, Montana, New Mexico, Oregon, and Utah, 356-7.

USEFUL INFORMATION.—Don'ts for the Varnish Room; Fine Lubricating Oil; Cure for Wart; Oilstone and Oilstone Powder, 359.

GOOD HEALTH.—Treatment of Carbuncle by Carbolic Acid; Trichinosis; Cancer; Important to Bread Eaters, 359.

NEWS IN BRIEF, on page 364 and other pages.

## Business Announcements.

Automatic Quicksilver Feeder—P. B. DuBois, S. F.  
 Assessment Notice—Wolverine Gravel M. Co.

## Passing Events.

While the prices of stocks have been pretty well up, there has been no special occasion for it as far as any change in the mining situation is concerned. The breakage of the big pump on the Comstock last week was a discouraging event, which it was supposed would "settle" the stock market for some little time; but it is evidently considered that the situation is very bad.

News from up in the Alaska region, lately to hand, is to the effect that reports, though a little exaggerated, have not been very much out of the way. Some people think the best way to prospect up there is by means of a steam launch. There is plenty of internal water communication in Alaska, so it is easy to go from one place to another. But the underbrush and timber obstructs walking. It is easier therefore to go from place to place by water and prospect wherever open ground is found.

The hills are now covered with prospectors in every direction. The season is fully opened everywhere, and miners who have been idle during the winter are now tramping over the hills hunting "prospects."

The "copper boom," of which we have written of late, still continues. Copper properties are now valuable everywhere. We shall very shortly give a description and engraving of the form of furnace most in use on this coast for copper smelting.

LEAD.—Last week 9,787 centals of lead were received in this city. Since January 1st, 18,579 centals of base bullion have been received in this city, and 33,839 centals of lead. Pig lead is worth 4½ and 5 cents.

PROSPECTORS are beginning to work in Idaho and Montana.

A LARGE deposit of garnets has been found near Calpella, Mendocino county.

## Color of Minerals.

The color of a substance depends upon its power of absorbing certain portions of the light; that is, certain rays of the spectrum; a yellow mineral, for instance, absorbs all the rays of the spectrum with the exception of the yellow. In general the color which the eyes perceive is the result of the mixture of those rays which are not absorbed. All minerals may be divided into two classes, according to Dana. 1st, those whose color is essential and belongs to the finest particles mechanically made; 2d, those whose color is non-essential and in the fine powder is different from what it is in the mass.

It is obvious from these distinctions, continues Dana, that the color of the powder or the streak, as it is called, is often a very important quality in distinguishing minerals. The streak is obtained by scratching the surface of the mineral with a knife or file, or still better, if not too hard, by rubbing it on an unpolished porcelain surface.

To the first class mentioned belong the metals and many metallic minerals; for instance, the streak of the black manganese oxides is black; that of hematite, which is red by transmitted light, is red, and so on. To the second class belong the silicates, and, in fact, the large part of all minerals. With them the color is often unessential, being generally due to small admixtures of some metallic oxide, to some carbon compound, or some foreign substance in a finely divided state. Most of these have a white or light-colored streak. For example, the streak of black, green, red and blue tourmaline varies little from white.

Iridesence is the presentation of prismatic colors in the interior of a crystal. The phenomenon of the play of colors, iridesence, etc., are sometimes to be explained by the presence of minute foreign crystals, in parallel positions; more generally, however, they are caused by the presence of fine cleavage, lamellae, in the light reflected from which interference takes place, analogous to the well-known Newton's rings.

## Miners and Mine Products.

Summaries of the statistical portions of the reports of Her Majesty's Inspector of Mines, show that in 1878 there were employed in the coal mines of Great Britain and Ireland 475,329 persons, of which number 382,929 were miners underground, and 92,350 were employed on the surface. The *Berg und Huttenmaennische Zeitung*, which summarizes the figures, says the underground hands were composed of:

474 boys from 10 to 12 years of age.  
 6,798 boys from 12 to 13 years of age.  
 38,669 boys from 13 to 16 years of age.  
 338,143 men over 16 years of age.

The surface hands are segregated as follows:

752 boys from 10 to 13 years of age.  
 521 girls from 10 to 16 years of age.  
 6,873 boys from 13 to 16 years of age.  
 438 girls from 13 to 16 years of age.  
 4,502 women 16 years of age and upwards.  
 19,769 men 16 years of age and upwards.

These figures show what a large number of persons there are directly interested in the actual mining work of getting the coal.

It is, however, more interesting to note what these employees produced. During the year when these 475,329 people were at work the output of the mines was as follows: 132,612,063 tons of stone coal; 10,747,227 tons of iron ore; 1,625,586 tons of fire-clay; 813,262 tons of coal shale and enclosing pyrites and building stone; 25 tons of petroleum from Derbyshire.

This was not all, however, for the figures given were only for coal, iron, etc. The statistics to give the range of the whole subject, must include more than this. In the extraction and handling of metals and metallic ores and other useful minerals. There were employed underground:

81 boys from 12 to 13 years.  
 824 boys from 13 to 16 years.  
 29,609 men over 16 years and upwards.

Surface hands were as follows:

627 boys and 96 girls 8 to 13 years.  
 4,339 boys and 981 girls 13 to 18 years.  
 1,741 women and 13,060 men 18 years and upwards.

The product obtained with this labor was as follows: Gold, 702 ozs., 16 dwt., 8 grs.; gold ore, 2 qrs., 26½ lbs.; silver, 153 ozs.; silver ore, 86 tons; cement silver, 8 cwt., 2 qrs.; copper ore, 54,568 tons; cement copper, 532 tons; coal ore, 98 tons; tin ore, dressed, 13,632 tons; tin ore not thoroughly dressed, 950 tons; tin ore, raw, 9,847 tons; uranium ore, 8 cwt.; zinc ore, 24,682 tons; manganese ore, 1,734 tons; arsenic, 4,464 tons; arsenical pyrites, 3,638 tons; ochre, 2,805 tons; rock salt, 182,930 tons; salt, (extracted from water), 1,500,000 tons; iron ore, 2,559,333 tons; pyrites, 14,759 tons; barytes, 21,715 tons. There were, also, quantities of building stone, cement, paving stones, lime stone, gypsum, etc., etc.

These condensed statements show what a very large product the mines of Great Britain give; and how many men, women and children contribute their labor in this direction.

The annual report of the Jocinstita mining company shows a cash balance on hand of \$277,035.29, being the net profit of operation from August 2, 1880, to March 1, 1881. The property of the company is at St. Ignacio, State of Sinaloa, Mexico.

## Taking up Coal Lands.

People who have tried it find that to acquire legal title to coal lands is considerable trouble. For instance, timber lands containing coal are not subject to sale. If an association takes up coal land each one must be 21 years old and a citizen of the United States. Coal lands are, of course, excluded, as mines, from pre-emption. But the great trouble is that you cannot acquire title until the land is surveyed. In the new fields of Arizona, New Mexico, Alaska, etc., a man cannot now acquire legal title by reason of the land not being surveyed. No land can be entered under the provisions of the coal act, until the same has been surveyed, the coal act declaring in the first section of it, "That any person, etc., shall have the right to enter by legal subdivisions." Of course, there can be no legal subdivisions on the unsurveyed public domain.

A correspondent of the Salt Lake Tribune, who has hunted this matter up in Washington, says, that in this dilemma the General Land Office has been asked many times to point out some way of acquiring title so as to protect the discoverer of coal under these circumstances. But the Commissioner steadily refuses to give advice upon the subject because methods that would be effectual in one community would not be so in another. He tells all, however, the same old story that no steps can be taken to secure title from the Government until the township plat is on file in the local Land Office, and that should a conflict arise as to the right to make the entry, priority of possession and improvements would govern.

With 60 or more thousands of emigrants coming into the country each month, and a majority of these going into the wilderness, as it were, it does seem as though Congress should provide some means of completing the survey of all public lands at an early date. But Congressmen, as a rule, do not have much foresight.

In reply to a recent inquiry, the Commissioner of the General Land Office says: "I will not undertake to say what is the precise degree of value necessary to bring coal lands under the operation of the coal act. The fact of the land being mined and coal being taken out, would be sufficient to determine the character of the land and to exempt it from the operation of the homestead law. Whether the coal is of an inferior or a superior quality, it is still coal, and subject to disposition under the coal act."

## A Smelting Oven.

R. P. Wilson, of New York, has devised what he calls a smelting oven, the object of which is to provide a system of treating ores and minerals, whereby the impurities which now enter into smelted iron or base bullion of the precious metals cannot enter and mix with the same, thereby causing said metals to be produced in a pure state, direct from the ores.

The invention consists in the arrangement and construction of a series of upright retorts, set in an inclosed furnace, so that the heat in the furnace will pass around and below the outside of the retorte and heat them to any degree required for the treatment or smelting of the various ores.

The retorts are constructed with one or two openings or branches near the lower end, for the purpose of withdrawing the mineral or slag. They are also made with an opening or branch near the upper end of the retorts, for the exit of gases into a pipe leading to the condensing chamber.

The idea of this inventor appears to be that, inasmuch as mixing ore and fuel together tends to cause impurities to be incorporated with the base metal, requiring subsequent treatment of an expensive character to purify the metals, he will keep the fuel separate from the ore by melting the latter in retorts. It does not seem, however, as the system shown would be very practical on a scale which would be necessary around large works.

## Mill Sites.

Mill sites may be located under the provisions of the mining act, and must be recorded. Locators of mining claims have the exclusive right of possession of the surface ground included within the lines of their locations, upon compliance with the laws of the United States, and with the State, Territorial and local regulations governing their possessory titles, where no adverse claim existed before May 10, 1872. But a mill site must be on non-mineral land. The owners of the mill site are entitled to the timber growing thereon.

It is the rule in the General Land Office under Section 2,337, United States Revised Statutes, to require that mill sites shall be located and recorded in the same manner as a vein or lode, and in case of a mill site not held and worked in connection with a lode claim, the customary certificate that \$500 worth of improvements have been placed upon the claim is demanded.

Mill sites can only be five acres, and on no consideration can more be taken up.

## Deep Mines in Idaho.

It is now pretty well conceded that the Wood River country, Challis, Sawtooth, and the other neighboring regions in Idaho, will be very profitable if the mines "go down." This "going down" is a question everywhere. Miners don't believe much in surface deposits. They think the ledges, to pay well, must be better below. Then they are assured of plenty of ore. There is such a very large number of mines in the districts of the regions above alluded to, that if one in a hundred only turn out rich at great depth, they will encourage a great many to put in their best licks in sinking. The "if" about the depth can only be decided by time and experience, but there are some pretty deep mines already. A correspondent, who is now at Wood River, in speaking of the depth of mines, speaks of several which are now pretty well developed. He says:

"In the Sawtooth district we have the Visnna down 600 ft., the Pilgrim nearly 100, the Smiley property 125, and others nearly the same depth, with an improvement in all of them as depth is attained. In Galena district we have the Eunics, the Gladiator, the White Cloud and others down from 75 to 200 ft., with the same result. In Warm Spring district we have the North Star on the East Fork and a number of others on Warm Spring creek, which are developed to a depth of from 50 to 150 ft. In Greenhorn gulch are several which are down from 50 to 185 ft., while around Bellevue the Mayflower, the Jay Gould, the Idahoan and several others have sufficient ore in sight to be admitted by the most fastidious to be very valuable properties. Near Jacobs City and around Bellevue there are numerous ledges that have been tapped at a sufficient depth to require years to work out the ore that has already been exposed. Now, why continue to use that ever-ready 'if'! Besides the mines referred to above, there are hundreds of locations which look well and give promise of being equally as good. Now, suppose one in one hundred of these prospects should be a good mine, and 99 out of 100 should fail to go down, we still have mines enough to make a good country."

## Large Grant of Mineral Lands.

The immense tract of land which has been granted by the Mexican Government to Samuel Brannan, a pioneer resident of California, in return for his assistance with men, money and arms during the invasion of Mexico by France, is a valuable one in minerals. The section is about 250 miles east of the port of Guaymas. It constitutes what has been known for years as the Yaqui country, and is justly regarded as the richest portion of Sonora. Within its confines are some of the fabulously rich silver mines which yielded so much revenue to the Spaniards prior to the earlier portion of this century. It is richly wooded and watered, contains very fine grazing and agricultural lands, and is conceded by those most conversant with the resources of Sonora to be the garden spot of northwestern Mexico.

Mr. Brannan expects to colonize the tract with Californians and Nevadans. He is to give 100 acres of land and a town lot to each one. By concession all goods for immigrants are to be free of duty and no tax or military duty will be called for for 10 years. Mr. Brannan is now in this city.

The *Arizona Journal* says that the land grant consists of 42 square leagues of land, at any point which Mr. Brannan may select in that portion of Sonora which lies between the Yaqui and Mayo rivers. This grant is to be supplemented by an additional 42 square leagues as soon as Mr. Brannan shall have settled up the first portion, making a total of 756 square miles of territory—a good sized principality of itself. To this has been added a franchise to construct a railroad from any point within the grant to any point on any railroad from El Paso to Guaymas that may be selected by Mr. Brannan, the franchise to exist for 99 years.

EDISON'S LIGHT.—One of Edison's electric lights, brought to this coast by Major McLaughlin, and to this city by Mr. Glass, of the Spring Valley hydraulic mine, was exhibited at the American District Telegraph Co.'s office on Wednesday night. The invention consists of a hulons-shaped glass three inches in length and two in diameter, and gradually tapering to the stand upon which it rests. The glass bulb is exhausted. Passing up into the vacuum from the base are two platinum wires, around which the glass has been closely blown, and at the end of each of these wires is a carbon point. From each of these points is a semi-circular piece of carbonized hainho no thicker than a piece of thread. The platinum wires were connected with a chemical battery and the electric current regulated by means of a key similar to those connected with gas fixtures, and, this being opened, a light was produced on the semi-circular piece of carbonized hainho. The light produced was steady, soft and not hurtful to the eye. The inventor claims that the carbon points, if perfect, will last three years.

## Notes of a Trip to Yosemite.

(Written for the PRESS by G. H. S.)

Leaving San Francisco on the Overland train at 3.30 p. m., on upon the Los Angeles and Southern at 4, the tourist makes a pleasant journey of about four and a half hours to Stockton in the cool portion of the day, arriving at the Yosemite house, Stockton, in ample time for dinner. Breakfast in time to take the 8 o'clock train for Milton, 28 miles from Stockton, at which point the coaches of the Big Oak Flat route are ready to receive him. From this point the road, which is very good, enters the hills at once, thus avoiding a hot, dusty ride through the flat valley lands, and winding through the hills, where there is a cool, pleasant breeze, it brings him to Copperopolis in time for dinner. Here are located many copper mines, among them the famous "Union," which formerly employed 300 men for some years, but which is at present shut down. A company is now using the water from the mines, which is strongly impregnated.

This water is hoisted up in tubs from a depth of about 18 ft., and is discharged over ore dumps through which it passes. From these it is led into tubs and sluices in which old scrap iron, sheet tin, etc., is placed. The action of this acidulated water dissolves the iron and when this is effected a clean up is made, and the copper which has been deposited is collected. About six inches of water is run through, and the company pay the owners of the mine one-fifth of the result.

It is said that an English company have offered \$50,000 for this mine and been refused. Taxes have been assessed against it for this valuation the present year, and this may result in its being worked again shortly.

Leaving Copperopolis large cattle ranges are passed, some of them two miles square, while the roadside is dotted at intervals with neat cottages, vineyards, and fruit orchards.

As the road runs deeper into the mountains the scenery becomes more interesting, and the wonderful Table mountain range lies along the road for a number of miles. It is apparently a basaltic formation, having a breadth of from 200 to 500 ft. upon the top, and is almost perfectly level, having sides which are perpendicular down to the slope which falls away from its foot. These perpendicular sides vary in height from 30 to 150 ft., and are a prominent feature of the landscape for many miles. This formation is somewhat broken at its lower end and is cleft entirely across by the Stanislaus river which cuts through it at a point near where the road crosses the river, but after a few miles it becomes a long, level unbroken table extending northward through several counties. The whole of the hills and mountains hereabouts, from some distance below Milton and along the line of the stage road present the appearance of having been subjected to the action of water similar to the beaches and rocks of a sea or lake shore.

The Stanislaus is crossed by a bridge at Burns' Ferry, and over an undulating road the route lies to Chinese Camp, a mining town which was formerly a scene of buoy activity, but has now fallen to decay, and, with its streets of empty and deserted brick, stone and fire-proof buildings, is but a monument of its former greatness.

The third stage of the day's journey commences here, and after leaving we soon come in sight of the Tuolumne river, which is reached by a rapid descent of about 800 ft. We cross Woods' creek, just above its junction with the Tuolumne, and stop in the little town of Jacksonville, formerly containing a large population, but now reduced to a few inhabitants. The principal portion of the town was washed away by a flood several years ago, and has never been rebuilt. From this point there is a beautiful drive of some miles along the banks of the river to the ferry (Haswell's), where we cross by a boat guided by a strong wire cable and driven by the current, which is quite rapid. Another three miles, through old and partially deserted placer diggings, with here and there some work going on, brings us to the foot of the mountain, at the top of which stands the famous

## Priest's Hotel,

Where our day's journey ends. In two miles we ascend 1,400 ft., but the road is good, and indeed, after the first few miles from Milton, but little dust is encountered, as there is no heavy teaming of any consequence upon this road.

We were awakened early this morning, and found a breakfast awaiting us, which still lingers in the memory. Very few of the wayside houses provide so well for the comfort of the traveler as Priest's.

The air is cool and bracing but not sufficiently so for any heavy wraps, and all being seated in the coach we move out over a road which is very smooth and pleasantly undulating for some miles, passing through Big Oak Flat where the gigantic oak, long since overturned, lies close to the road. Garrote and other small places are passed in succession, and as we continue to rise the trees become larger and the forests denser.

Although the altitude seems to us great at Priest's, we are still going up, up, until it seems as if the top will never be reached, but when the summit is finally passed, we rattle down towards the valley at a lively pace. Patches of snow still linger near the road, and in the distance the mountain peaks are covered. After a few miles we reach the grade road which finally leads us

## Into the Valley,

And everybody is now anxious to catch the first glimpse of the wonderful Yosemite. The road is admirably built with immense stones laid up in walls, and winds downward like a Jacob's ladder, so that we see our road almost beneath us for a thousand feet. At all the turns we have a fine view of the Bridal Veil fall, which like all the others is now very full of water. We are more than compensated for our early start this morning by the beautiful prismatic tints formed by the declining sun, and those tints are so blended and confused in

bridge where the trail crosses it forms what is well-named "the Diamond Cascade." Just below this it flows over a smooth but steep incline with a beautiful pulsating movement, forming what is called the "Silver Flume," terminating in the "Emerald Pool," where the water lies in a quiet lake before plunging over the "Vernal Fall."

The route the next morning took us to Glacier Point.

And the Sentinel Domes, which is behind and far above the Sentinel seen from the valley. Starting at 9 o'clock, the usual hour for the different saddle trains to leave, we wind along up this mountain side upon a zigzag trail of much greater width than I had supposed it was possible to build. The trails are all comparatively easy, and are kept in good repair, so that, except for the fatigue of riding all day upon such steep inclines, no one need be deterred from most of the trips.

The saddle trains consist of some sixty animals, mostly horses, gentle and well-broken, and very sure-footed. They need hardly any guidance, being so accustomed to follow each other that one may ride to the very top of any of the trails without touching a rein.

As we ascend the trail the view of the valley becomes gradually more extended and beautiful, until we reach our first resting place, Union Point, from which the hotel directly beneath us looks like a doll's play-house. Close to this point and just below the trail stands the Agassiz column, a peculiar oblong or bottle-shaped rock, standing vertically upon a base about its own diameter, but apparently entirely separate from

down the valley, and to the Cascades, still farther down in the narrow gorges, through which the river makes its final exit from the valley. A short walk from the hotel, across the bridge and the narrow intervening valley, brings us to the foot of the lower falls of the Yosemite, but the volume of water which is now pouring over it, aided by the strong breeze, makes it impossible to approach very near without being completely wet through by the drifting spray.

## A Portable Mining Flume.

A short time since the MINING AND SCIENTIFIC PRESS Patent Agency obtained for James Howe and Nelson Waite, of Shasta, Shasta Co., a patent for an improved method of constructing portable mining flumes, either for the purpose of working new ground or to carry off tailings. It consists essentially of a framework which is so constructed as to support the side boards of a flume without the necessity of any bottom or the use of the bracing usually employed upon flumes. This enables the miner to build the flums by simply setting it on the ground, and when working new ground it will gradually settle down, the earth caving into it and being washed down until the flume has reached the bed-rock, side boards being added as fast as may be necessary. The flums could be built without the necessity and expense of excavating to bed-rock.

Mr. Waite, who is now in San Francisco, says they have been using the flume, and it is a very great improvement for working flat land. When set on the surface, with a little dirt or brush thrown against the outer sides to hold it steady till it settles, it will work itself down. The water begins to excavate at the lower ends of the flume, gradually working back toward the head; and as the flume settles, new side boards are added. Not having any bottom it may be sunk at any point.

The principle of the flume is the same as that of parallel jetties. The water flow is confined between the enclosing sides of the flume, and by being thus confined directs its energy in tearing away the bottom. Thus, it digs a trench for itself. As this trench increases in depth, the side boards of the flume are added, the flume settling down gradually. Length after length may be added, and tailings carried on in this manner to any required distance.

Mr. Waite is of the opinion that this principle may be tried with success on the debris in the river. He thinks that if flumes of this kind were put in at different distances along on the river, so as to straighten the channel and confine the current, the debris could be kept moving in the river to the tule lands and broad flats of Suisun bay. He has devised a plan for this. He puts a row of uprights of iron or wood, backed by a corresponding row, connected by braces. Opposite this is a corresponding double row of uprights. As soon as sides are put in this forms a flume to direct the channel. As the debris is moved from between the "jetties," the sides are pushed down, the channel between thus constantly deepening until by and by the whole water flow concentrates here. This cuts away the bottom very rapidly. The piles or uprights ought to be of iron, Mr. Waite thinks, but the sides may be of plank.

Where the water spreads so every time it turns, it forms a bar; but when confined no bar forms. If the debris is brought into the upper bay and rivers kept clear, while portions of the bay would naturally fill up, a channel would be kept open by the strong tidal currents, aided by those formed by the river flow. There would be then one deep channel. Mr. Waite is very anxious to have a section of these flumes or temporary jetties put in on some of the upper rivers, to prove the correctness of his theory. They want a channel and want no flume with a bottom, which would be too expensive. This would make the water cut its own channel the same as Mr. Eads' jetties, at the mouth of the Mississippi, caused a deepening of the channel there. The principle is the same, the means of carrying it out forming the only difference. This system would, of course, be more economical. Sometimes, Mr. Waite says, the bank of the river could be used for one side, and the jetties for the other. In such cases, half the expense would be saved.

TWENTY-FIVE carloads of the Moulton mill machinery have been shipped from the East since the 1st of May.

CATHEDRAL PEAK GROUP, OF THE HIGH SIERRAS, BEYOND THE YOSEMITE VALLEY.

the mass of mist and spray which is thrown out from the foot of the fall, that it looks like a ruined rainbow. Still continuing the descent, we finally reach the valley, and as we ride along we have a nearer view of the Bridal Veil fall; then upon the opposite side the Ribbon fall, or Virgin's Tears as it is sometimes called, and just beyond, To-tock-ah-nu-lah, or El Capitán. Just beyond this are the "Three Brothers," or as the Indians call them, Pom-pom-paus, (mountains playing leap-frog), and beyond this we catch the first glimpse of the Yosemite upper fall. The Cathedral Spire is passed upon the right, and the "Sentinel," "North Dome," "South Dome," "Royal Arches," "Washington's Tower," "Cloud's Rest," and other points appear in the distance. We soon pass the lower hotel, the little chapel and middle hotel, and continuing our journey for another half mile we finally alight at Barnard's hotel (Formerly Hutchings) at about four o'clock in the afternoon.

This being Mr. Hutchings' original selection is one of the finest locations in the valley. The Merced river flows so closely to the rear porch that one might take a "header" into its clear water, but for the restraining thought that the water is "just off the ice" a few miles above.

The booming roar of the great waterfall is a sufficient lullaby for the tired travelers, and the fresh mountain air seems a wonderful restorative, for this morning found us quite ready for our first excursion, which we made up the valley to the

## Vernal and Nevada Falls,

Stopping at Snow's hotel for lunch. The level road up the valley is easy and picturesque, and after sufficiently admiring the Vernal fall we again mount our horses and commence the ascent of the winding trail to the Nevada fall, which we reach before noon. The streams are all full of water from the melting snows, and the beauty of all the falls is correspondingly increased. From the foot of the Nevada fall the water tumbles down its rocky channel, and at the

it, and so delicately balanced that but little would be required to overthrow it.

Although we are now at an altitude of 2,200 ft., the guide informs us that we are only half way to the top, and we resume our upward journey after a short rest.

Glacier Point is one of the prominent points of observation, and gives one of the finest views in the valley. After lunch at this place we ride to the top of Sentinel Dome, from which most of the great mountains of the Merced group and the Sierras, beyond the South Dome and Cloud's Rest, are visible. Nothing has so grown and impressed me with its grandeur as the great South Dome. Yesterday on the trip to Vernal and Nevada Falls, the great North Dome, Cap of Liberty or Mt. Broderick divided the honors with it, as it did not appear so much larger, as it really is; but to-day as we go up, the other mountains gradually sink into the landscape, while the South Dome seems to rise higher; and when finally we surmount the Sentinel Dome, its rounded, smooth summit still seems hundreds of feet above us.

Before we reach the top of Sentinel Dome we are obliged to cross a body of snow six or eight ft. deep, but solid enough to allow the horses to walk upon it without sinking more than half knee deep. A strong wind was blowing when we reached the summit, and, after a short stay, we again commenced our descent.

The descent is quite as fatiguing as the ascent, but is safely accomplished by everybody, even ladies who have never before been in the saddle, and we arrive at the hotel by half past four in the afternoon.

The following three days were spent mostly in the valley. We made an early morning trip to Mirror lake, about three miles above the hotel, to see the wonderful reflection of the surrounding mountains in its dark waters, and the effect of the sunrise through a tree fringed depression in the mountains, after which the surface became suddenly ruffled and it is finished for that day.

Another trip is made to the Bridal Veil falls,

## THE PELTON WATER WHEEL.

(Patented, Oct. 26, 1880.)

This water wheel has been thoroughly tested with the Dynamometer, and utilizes 78% of the theoretical power, and underheads of water of 75 to 800 ft is guaranteed to give better satisfaction than any Turbine or other wheel ever offered to the public. The above per cent. is due to the peculiar shape of the buckets used. They do not reduce the water to a spray, but divide and deflect it outward and backward, in such a manner that a part of the impact and the whole reactionary force are utilized, without any part of the water coming in contact with the bucket following. Furthermore, the per cent. of efficiency remains constant through great variations in the amount of water used. These buckets can be taken off in transportation, and can be replaced by new ones when worn out by sand in the water; also can be applied to wooden wheels when desired.

HERCULES SLAYING THE GIANTS.

## HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade

PATENTED IN THE UNITED STATES PATENT OFFICE.

## THE CALIFORNIA POWDER WORKS,

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and HERCULES Powder.  
ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street, - - - San Francisco, Cal

## MOREY & SPERRY,

MANUFACTURERS OF

Gold and Silver Grinding and Amalgamating Machinery

HOWLAND'S PULVERIZER Takes the Place of the Cumbrous Stamp Mill and can be put up in one day ready for work.

IT HAS BEEN FULLY PROVED AND TESTED.

It weighs complete, 7,000 pounds. It costs \$1,500 ready for the belt. Will crush one ton per hour of hard quartz that will pass through a 40 mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.

Stamp Mill is, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores. Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill supplies. Iron Work complete for Wood Frames, also.

SPERRY'S  
WROUGHT IRON FRAME  
FOR STAMP MILLS.

Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.

MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

## LEFFEL'S IMPROVED WATER WHEEL.

PRICES REDUCED!

PATENTS REISSUED 1868.

The "OLD RELIABLE" with improvements, making it

THE MOST PERFECT TURBINE NOW IN USE.

Comprising the Largest and the Smallest Wheels, under both the Highest and Lowest head used in this country. Our new Illustrated Book sent free to those owning water power.

Those improving water power should not fail to write us for New Prices, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address

JAMES LEFFEL & CO., Springfield, Ohio,  
and 110 Liberty St., N. Y. City.

EDWARD G. DENNISTON, PROPRIETOR.

Awarded First Premium at Every Fair of the Mechanics' Institute for the Last Twelve Years.

MANUFACTURED UNDER A NOBEL'S ORIGINAL AND ONLY VALID NITRO-OLYGERINE PATENTS.

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive

**Judson Powder**

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. Triple Force Caps and all Grades of Fuse.

**BANDMANN, NIELSEN & CO.,**

SAN FRANCISCO, CAL.

**\$1,000 CHALLENGE!****THE FRUE ORE CONCENTRATOR.**

Over 250 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

Saves from 50 to 100 per cent. more than any other Concentrator in use, and the concentrations are clean from the first working.

The wear and tear are merely nominal; the water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of \$1,000 each, and we mean business.

ADAMS & CARTER, Agents, Room 7, No. 109 California Street, S. F.

**EXCELSIOR BLASTING POWDER**

MANUFACTURED BY THE

Excelsior Powder Company.

This is no so-called "safety" Powder, but a powerful explosive, and as safe to handle and use as any nitro-glycerine Powder on the continent. There is no headache or nausea in the use of this Powder, as the noxious fumes are entirely done away with. It is put up in cartridges of any size to suit consumers and is exploded with cap and fuse, the same as any other high explosive. The following testimonial is a sample of hundreds of the same tenor being constantly received:

GOLD HILL, August 17, 1880.

AGENT EXCELSIOR POWDER CO.—Dear Sir:—I have used your Powder in test cement and hard blasting rock, and find it superior to any Powder in use on the Coast. It does its work effectually, and does not leave the person using it with a severe headache, like the other Powders do to the majority of miners. In recommending it I would suggest, give it a fair trial and I am confident it will speak for itself. Wishing your Company success,

I am respectfully yours, etc.,

GEORGE OLARK,

Foreman Sierra G. and S. M. Co.

### Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

**SICKLE BARS FOR HARVESTERS.**—V. R. Ostrom, Modesto, Cal. Dated May 24, 1881. No. 241,878. The improvement in sickle bars is one, the object of which is to prevent the grain from falling off when the front of the header is depressed at an angle to cut low grain. In operating headers, when the front is depressed to cut low grain, the upper surface of the bar has a downward inclination, and there being no obstruction, the grain which falls to be caught by the traveling draper is liable to slip forward again onto the ground. A considerable portion is thus lost. The invention, which is designed to lessen this loss, consists essentially of a finger or sickle bar made of a single iron strip so secured to a beam as to have a vertical side raised above the level of the draper, a wall being thus formed and the grain prevented from slipping forward when the front of the header is depressed to cut low grain.

**CABINET JEWELRY.**—Wm. L. Miller, S. F. Dated, May 24, 1881. (Re-issue). No. 9,723. This invention relates to an improvement in the manufacture of a style of jewelry known as "cabinet," in which the ornamentation consists in filling a cavity in the face of the article with finely divided particles of ore, or other other substances, and covering it with a transparent face. The particles are generally put in from the front and the glass put over them. In doing this the particles cannot be prevented from shifting their position, the friction causing dust to form and settle on the glass. Mr. Miller fixes the glass cover or face in position, and filling the particles into the cavities with a cement or putty over the under side of the compartments, so as to press the front particles snugly against the glass and fix them immovably when the glass is in place.

**BLACKING COMPOUND.**—George E. Miller, Austin, Nev. Dated May 24, 1881. No. 241,876. The object of this invention is to provide a blacking compound for boots, shoes, harness, trunks, carriage tops and other leather articles. Its qualities are durability, susceptibility of high polish, cleanliness, imperviousness to water and snow, protection to leather, harmlessness therein, more capacity for rapid drying. The compound combines all the best effects of a blacking and can be used for ladies' or gentlemen's shoes.

**SHIRTS.**—David Neustadter, S. F. Dated May 24, 1881. No. 242,023. This invention relates to certain improvements in shirts and similar garments. It is a method of strengthening hack openings by facing extending the entire length of said openings. The overlapping strips are stitched to both the edges of the opening and across its lower end, and combined so as to form a finish and re-enforce.

**SUSPENDERS.**—W. A. McFarlane, Ivanpah, San Bernardino county, Cal. Dated May 24, 1881. No. 241,874. The invention consists in providing the ends of suspenders with an elastic band and detachable buckles and holders connected therewith. The object is to provide suspenders, the attachments of which will be serviceable and easily removable.

**NITRO-GLYCERINE.**—Gilbert S. Dean, S. F. Dated May 24, 1881. No. 241,941. The object of this invention is to increase the safety of nitro-glycerine compounds in handling or transportation. It consists essentially in mixing it with a pulverulent nitro-compound and water.

The completion of the Atchison, Topeka and Santa Fe railroad through Sonora, Mexico, will develop important anthracite coal deposits. It is 115 miles from Guaymas. There is exposed five or six ft. of the vein, the foot walls not being in sight.

### Alaska Mines.

Reports from the Takon mines, Alaska, are to the effect that while the earlier reports are exaggerated, the mines will in due time prove rich and permanent. The ledges are all gold bearing, in a slate formation. They vary from two to eight ft. in width, with an easterly dip of 65° and a northwest and southeast trend. The rich boulders said to have been found on the beach were not found at all. The thing was a baseless rumor. Harrisburg, with 80 inhabitants, is 180 miles by water from Sitka, but only 75 miles by a direct line. Another new camp is reported eight miles from Harriburg, and a town called Providence has been started. The ledges are large and gold bearing. A correspondent of the *Chronicle* sums up the situation at Harrisburg as follows:

The mineral belt seems to be about two miles in width, has been explored a distance of about six miles northerly and southerly, and is situated about four miles inland from the coast, at an elevation of from 1,500 to 2,000 ft. above the sea level. But little work has been done as yet on any of the numerous locations. Nearly all the labor thus far has been expended in cutting trails, building houses, and getting ready to mine. The large amount of snow that falls here will be a serious detriment to the speedy development of the mines and a thorough prospecting of the district. I would not recommend this as a poor man's country, nor would I recommend a poor man to come here; he cannot get around with a little money. The prospector cannot even carry his own blankets here. The mountains are very precipitous, and so thickly covered with underbrush as to render it impossible to get far from a trail. It requires at least three Indians to carry blankets, camp equipments, etc., for one prospector. Mr. Indian must be fed and paid. The best and most feasible way to prospect in this country would be with a small steam launch; one that could skirt the shores of the numerous inlets, and search for float ore, and, when it was found, follow it up the mountain to where it originally came from. In that way a party could very thoroughly prospect the whole coast range, and would, no doubt, make some valuable discoveries during a season, especially north of this camp.

### Botany in Southern California.

**EDITORS PRESS.**—Many disappointed mining explorers have turned their attention to agricultural pursuits, but it is more seldom that they become enthusiastic devotees of botanical science, hence a marked example of the latter unusual condition, seems deserving of record.

Parish Bros. S. B. & Wm., occasional contributors to horticultural journals, and still more widely known by the valuable additions they have made, and are still making to choice garden novelties, after an honorable service in the Union army during the war of rebellion, and a subsequent hard experience with the miner's pick and shovel, through the wilds of Utah and Arizona, eventually turned their attention to developing the more substantial agricultural wealth of the rich San Bernardino valley.

Finding a sheltered nook near the banks of the Santa Ana, they gradually supplanted the cottonwoods and willows of the well-watered soil with vineyards and orchards, and in the modest bachelor quarters under the shade of a weeping willow, indulged in few mournful regrets as they saw the wilderness around them begin to blossom with something more than roses. A well-selected scientific library, with a good supply of horticultural publications inside formed a fitting complement to the increasing array of floral charms outside. Not content with the usual commonplace stock of ordinary gardens, they ransacked the neighboring hills and mountain slopes for native plants, and soon around their artesian fountain, pouring a constant stream of delicious coolness, was clustered many a strange denizen of rock, ravine, and desert waste, in strangely contrasted groups.

Here a bed of luscious Humboldt lilies with their brilliant spotted perianth overshadowed the slender forms of the light-yellow Parry lily, with its delicate perfume; trailing over the damp eoli, apparently as much at home as in the deep ravines of Lytle Creek canyon, was the delicate *Palmerella debilis*, with its festoons of bright, lobelia-like flowers, blooming freely in the bright sunlight, and showing its adaptations to cool greenhouse culture. *Pentstemons* of every shade and form were disputing the ground manfully with the more ordinary garden types.

In the drip of the fountain damp, mosses and delicate ferns find a congenial home, and an extemporized tank is appropriated by the rare yellow *Nymphaea* of Florida.

When the hot summer sun gives place to the shortening autumn days, the hospitable board is spread with luscious fruits, in which *Vitis* and *Pomona* are chief rivals, *Citrus* keeping in the back ground.

Through an inviting open door is the Parish Herbarium, the sanctum of the elder brother, Samuel B.; here safely stored in open pigeon holes, scientifically arranged, is the accumulated result of many seasons' work, extensive botanical correspondence, and what will eventually prove the nucleus of a standard collection of the native plants of Southern California.—*C. C. Parry, in Rural Press.*

### The Butte Boom.

Every day that passes makes it clearer that this city is destined soon to become one of the chief mining camps of the world. Here are found the only true fissure veins of silver ore yet discovered in this country, and unless all the signs mislead, the mines opened thus far are only an earnest of better to come, when capital and machinery begin their inevitable work in our midst. Wonders have already been worked with the limited facilities possessed by our miners, and to the faithful and persevering efforts of these plucky pioneers is due the fact that Butte now ranks as the most promising mining center of the United States. To reap the full harvest, however, it is necessary that outside capital shall be brought into the territory.

This most desirable end can be easily accomplished, and it can also be easily defeated. It can be accomplished by simply telling the truth about our mines. The mines and mining prospects of Butte are good enough to go before the world on their merits. There is no need to lie about them or to try to pass them off for better than they are. Let the simple truth be told regarding the quality and quantity of ore in sight and within easy reach in any of the developed mines in this district, and unlimited capital will come forward to earn a rich reward by doing the work required to realize on the raw product.

It shall be our duty in the future, as it has been our pleasure in the past, to give the public the fullest and most reliable information regarding the developments made in the various mines in Butte and the surrounding camps. We believe that by telling the plain, unvarnished truth about our mines, the city will be greatly benefited and the reputation and wealth of the territory will be vastly and rapidly increased. In a few brief months the whistle of the locomotive will reverberate in the mountains lying all about us, and with the railway will come thousands of pilgrims anxious to make their homes in our midst. There is room enough and wealth enough here for all that come with willing hearts and strong hands. Both the railway and the thousands of human beings and millions of capital that will accompany it should be met and welcomed in a liberal spirit by our citizens. Everything that helps to develop the wealth of our mine is a benefit to every thrifty individual in the community, and the business boom now beginning to make itself felt in Butte will soon make a rich metropolis of what five years ago was but a half deserted mining camp.—*Butte (Montana) Miner.*

### What is Arizona Good For?

Many people make a great mistake when they suppose that Arizona is good for nothing except for mining. The agricultural land, it is true, is comparatively small, yet we have enough good land, if we had the right kind of men to take hold and put it into cultivation, to raise all the grain necessary for the needs of the Territory. There are millions of acres of fine grazing lands in Arizona, if we only had water for the stock to drink.

We have no doubt this difficulty will be overcome in time. By sinking wells and opening up water channels in the mountains and foothills, which may be done in almost any of the higher ranges of mountains, plenty of water may be obtained. At comparatively little cost the water so obtained may be conducted to the low lands in pipes and watering troughs placed at convenient distances, and thus reclaim some of the finest grazing lands to be found in the West. Colorado is represented to possess over 300,000 head of cattle, besides thousands of sheep and horses. Arizona, perhaps, does not possess more than a third as many cattle as Colorado, but the day is not far distant when she will lead that State in the number of cattle produced. Arizona possesses many advantages over that State in stock raising. Most of our grasses are perennial; we have no severe cold weather or driving storms, which are so trying to stock; we never have to feed them during the winter season, as they do there; we have a reliable pasturage and will never have to drive stock in search of new feed, as they do in all northern latitudes and California. While we possess the finest silver and copper mines to be found in the world, we should not overlook our agricultural and stock lands, which are by no means limited, as many suppose. As we the case in California in early days, we are apt to overlook these interests in our anxiety to realize quickly from mines, but the time is coming when Arizona will export millions of dollars worth of live stock.—*Arizona Citizen.*

The jury in the case of the Iron Silver mining company vs. the Smuggler mine, Colorado, returned a verdict, Friday, in favor of the defendant.

The Lyon M. and M. Co.'s branch, connecting with the Carson and Colorado railroad is progressing rapidly. A half mile is already graded, and the track laid thereon.

Tombstone and Tucson are to be connected by telephones, which are coming into general use among the mining camps of Arizona.

Every day parties of prospectors leave Tucson, Arizona. Fully 100 prospectors and miners left last week.

### New Mexico.

There is no portion of the United States attracting more attention at this time than Arizona and New Mexico. The latter Territory is destined, at no distant day, to equal, if not eclipse, her sister Territories in magnitude, permanence and richness of her mineral deposits. Besides her mines of precious metals, the coal fields and iron deposits within her limits must eventually prove a permanent source of great wealth. As population increases, manufactures will spring into existence, giving thousands employment, and the great natural advantages of this wonderful section, with the Southern Continental railroad traversing its entire length, with three competing lines reaching her eastern boundary, this population will be secured within a period much shorter than is now supposed by the casual observer. A correspondent thus speaks of this coming country: "The whole mountain range through the Territory is one vast mineral belt. It was mineral wealth which first attracted the rapacious Spaniards in the early part of the sixteenth century, and the reputed treasures of the seven cities of Cibola, as reported by Friar Marcos de Niza, was a moving cause of its first conquest. Old mines have been continually re-opened, which have been buried under the debris of centuries, and American enterprise is daily discovering new ones. The White Oaks excitement of last year and the occupation of Cutillos, are followed by the opening of new districts this winter. Prominent among them are the discoveries made in the Magdalena range, west of Socorro, where great finds, both in silver and gold, are reported daily.

Its plateaus of nutritious grasses, its coal-fields, its deposits, its mine of lead, copper, silver and gold, its capacity for the shipment of wool and hides and cattle, its wondrously watered plains, its average mean temperature of climate, its salubrious and bracing air, its almost Italian sky, its promise as a wine-producing country, and last though not least, its curious remains of an early civilization, combine to give the republic assurance that New Mexico at no distant day will play an important part in the Southwest toward which the energy and enterprise of the land are so visibly gravitating."—*Arizona Journal.*

**ALL THAT GLITTERS IS NOT GOLD.**—As a rule, mining has in the past been attended with too much glitter, haste and superficial knowledge. An assay of a piece of ore found in a prospecting shaft has been time after time heralded through the country as a great strike in a rich mine. With as much reason might the product of a carefully watched garden spot 10 ft. square in the midst of a 160-acre homestead claim be given as the sample crop of a farm. A city is not built in a day, and a mine cannot be made at once. At the door of an unwise stock-buying and stock-selling much of the injury to legitimate mining must be laid. The pictures of wealth presented have been, by the magnifying glass of eager desire, brought so near that it seemed as if the hand could almost touch them, and men with stock for sale have labored faithfully and persistently to make the illusion true and to meet the popular demand for quick returns. The result has too often been disappointment and failure, and an unfavorable feeling full of distrust and injustice against an industry which is in every way worthy of the fullest confidence when rightly understood.—*Placer Times.*

The circulation of the standard silver dollar is practically stopped. During the fall and early winter there was quite a demand for the purpose of moving the crops. That demand stopped when the crop movement was over. Since the first of January there has been no call for silver, and all the dollars coined since remain in the Treasury. Moreover, the silver in circulation has found its way back to the vaults. The amount outstanding has steadily decreased. Coinage at the rate of a little over \$2,000,000 per month goes steadily on.

The owners of the East New York drift mine, situated in Steep Hollow, Nevada county, have had eight new cars built to be used in running out the dirt through the tunnel. Mr. Andrews put up the woodwork, and G. M. Halsey the ironwork of the cars. Seven of them are constructed with side dumps and one with movable bed and end dump. They have all been taken over to the mine. The cost was about \$80 each.—*Placer Times.*

Grading on the Denver, Western & Pacific is completed between Denver and Longmont, and the track-laying has begun. The graders are at work on the line west of Longmont. It is not yet decided whether this line to the mountains will be a broad-gauge. The road will be in operation from Denver to Longmont by September 1st.

SUPERINTENDENT ADAMS, of the Indian Queen property, near Benton, Mono county, says that the mine has enough ore in sight to insure, for eight or ten months to come, the company's regular dividends of \$17,000 to \$18,000 per month.

The surveyors engaged in the preliminary work of locating a railroad to the Deer Creek coal field, Arizona, have completed their survey from Wilcox to the mines, and are now going over the route from Picacho to Deer Creek.

A good deal of prospecting is now being done in the Walker River country.

## News in Brief.

SMALL-POX is waning in San Francisco.  
FRONTIER men anticipate Indian trouble in Nebraska.

FEARS are felt in Klickitat W. T., of a grass-hopper plague.

THERE is not a Chinaman in Vermont and none are needed.

TUCSON, A. T., has a yeast powder factory and several flour mills.

It is said that there are 1,200 acres of coal fields near Fort Wingate, A. T.

RECENT rains have insured abundant crops throughout western Washington Territory.

AN amendment to the Land bill, opposed by Gladstone, was defeated in the Commons by a vote of 163 to 46.

ONLY 104 persons out of 600 were saved from the disastrous wreck of the Victoria, Canada West, last week.

The first threshing of the season has begun in Salt River valley, and there will soon be new grain in central Arizona.

EDWARD TRICKETT, the Australian carman, and Kelly, ex-champion of England, sailed from London for New York on the 28th ult.

ONE THOUSAND union men in the iron works at Covington and Newport, Kentucky, have agreed to strike for an advance of wages.

MIDHAT PASHA declares that the story of the murder of Abdul Aziz is a tissue of falsehood, and that Abdul committed suicide.

SINCE the local option law went into effect in Massachusetts 46 towns have voted not to grant liquor licenses, and eight towns to license sales.

THE Trustees of the Napa Insane Asylum have purchased 402 acres of land from W. H. Coombs for \$12,000. This makes the Asylum property include about 900 acres.

THE announcement is made that the American line of steamships trading with Brazil has been suspended for lack of support. Subsidized British competition has destroyed it.

ELECTRIC lighting is in successful operation on more than 60 steamers of the Mississippi river and its tributaries. It is believed to add much to the safety of that kind of traffic and traveling.

THE work in the Southern Pacific Railroad machine shops in Los Angeles embraces all locomotive repairs pertaining to the Yuma, Los Angeles, Santa Monica, Wilmington and Santa Ana division.

THE Pimas on the Agency in Arizona are succeeding in farming. There are about 4,000 Indians on the reservation. Water has lately been brought through a six-mile ditch from the north branch of the Gila.

THE committee at Los Angeles who have examined the act of 1859, authorizing a division of the State of California, submitted their report Thursday, that said act is still valid, and that all that is needed to make it effective is the concurrence of Congress.

CHARLES and Thomas Gilchrist, with Thomas Sharpe, have secured the wood and timber contract from Bliss, Yerington & Co. for the Mono lake timber business. The contract calls for 30,000 cords of wood and 7,000,000 ft. of lumber, to be delivered at Bodie before next winter.

THE Santa Barbara Press states that 6,000 acres of land in that county have been disposed of at less than \$2 per acre. The owners of large grants and ranches of from 10,000 to 50,000 acres, who heretofore would not sell, are now dividing their land and parting with it at low figures.

UNDER orders from the War Department, Gen. Pope is stationing troops at accessible points for service in case there should be trouble with the Ute Indians when their removal under the Ute treaty is to be consummated. Care is taken that no movement of the troops likely to excite the Indians is made.

BLOSSOM's artesian well, lately sunk on his ranch near Battle Mountain, Nev., is pronounced the best in the State of Nevada. It is only 165 ft. deep, still it throws the water to a height of 10 ft. above the surface of the ground. The water is clear and pure, and flows at the rate of 50,000 gallons every 24 hours.

RINICRI, Governor of the National bank, Greece, is negotiating with the government in the name of DeLesseps, with a view to constructing a ship canal through the Isthmus of Corinth, to connect the waters of the Gulf of Corinth with those of the Aegean sea. It is believed that the convention on the subject will shortly be signed.

It is rumored that the North Pacific Coast railroad, together with its rolling stock, real estate, the lease of the San Rafael and San Quentin branch, and all other appurtenances of the road, has been transferred to the bondholders of the road, who will hereafter operate the line. It has been known for some time past that such a course of action has been under consideration.

THE narrow-gauge cars of the South Pacific Coast Railroad commenced to run from the depot, corner of 14th and Webster Sts., Oakland, over the new bridge to the company's landing at the creek, making close connection with all Alameda local and Santa Cruz through trains, and with boats to and from San Francisco. The time from San Francisco to Oakland over the new route is 40 minutes.

## Traveling Agents.

We want several canvassing agents who will make it their business to solicit subscriptions and advertising for our first-class progressive newspapers. Men of ability and experience can secure good pay and permanent employment. Send references and state your past occupation, etc., to the publishers of this paper.

## The Mining and Scientific Press

Is the leading mining journal in America, and enjoys a large circulation among the more intelligent operators and workers in the gold fields of the world.

As a scientific and mechanical representative of the Pacific Coast, it is decidedly popular and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivaled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer will find profit by its reading.

Subscription, \$4 a year in advance. Sample copies, post paid, 10 cents.

DEWEY & CO., Publishers.

## Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. F. OSBORN—San Francisco.  
A. C. ROSE—Pacific Coast and Sonoma county.  
C. W. MCCREW—Santa Clara county.  
M. P. OWEN—Santa Cruz county.  
J. W. A. WRIGHT—Merced, Tulare and Kern counties.  
JARED C. HOAG—California.  
R. W. CROWELL—Tehama and Butte counties.  
D. W. KELLUMER—Santa Barbara, Ventura and San Luis Obispo counties.  
A. LEONARD MEYER—Utah and Idaho Ter.

## Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct or if the paper should ever come beyond the time desired, be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omission of agents.

## Sewing Machines.

Several first-class styles, good as new, will be sold at a bargain. Call on or address H. F. D., at this office.

PERSONS receiving a sample copy of the MINING and SCIENTIFIC PRESS with this notice marked, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We will send it, on trial, at the rate of \$4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

Do NOT DELAY.—Send us your subscriptions promptly. Don't let any break occur in your subscriptions to the WATCHMAN. Every live Workman needs every number of the paper, and we need his assistance to print as valuable a journal as we strive for the special benefit of its patrons and the general good of the Fraternity. Send the cash direct, or, if more convenient, hand it in with your dues to the Financier and we will allow him for trouble and expense of remitting.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good way. A day at Woodward's Gardens is a day well spent.

By TELEPHONE.—Subscribers, advertisers and other patrons of this office can address orders, or make appointments with the proprietors or agents by telephone, as we are connected with the central system in San Francisco.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING and SCIENTIFIC PRESS which we will sell for \$3 per (half-yearly) volume. In cloth and leather binding, \$5. These volumes, complete, are scarce and valuable for future reference and library use.

How to STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

The State Mining Bureau, No. 313 Fine street, is open to the public from 10 o'clock A. M. to 5 o'clock P. M. daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

ECLIPSE ROCK DRILLS.

The Most Economical Air Compressors in the Market.

## MINERS' HORSE-POWER.

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The Power is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX,  
49 Fremont St., S. F.

## Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

## ANNUAL MEETING.

GOVER MILLING AND MINING COMPANY.—The regular Annual Meeting of the Stockholders, for the election of a Board of Directors, will be held on Tuesday, June the 14th, 1881, at 2 o'clock, P. M., at the office of the Company, No. 402 Front street, Room 8, San Francisco, California. W. O. WILSON, Secretary.

Wolverine Gravel Mining Company.—Location and principal place of business, San Francisco, California. Location of works, Roach Hill, Placer county, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the Thirty-first (31) day of May, 1881, an assessment, No. Two (2) of Ten (10) Cents per share was levied upon the capital stock of the Corporation, payable immediately to the Secretary, at the office of the Company, No. 325 Front Street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the First (1) day of July, 1881, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the First (1) day of August, 1881, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors. E. J. BLANDING, Secretary.

Office, No. 325 Front Street, San Francisco, Cal.

## DEWEY & CO.'S

Scientific Press

Patent Agency.

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old  
experienced, first-class Agency. We have able and trustworthy associates and Agents in Wash-  
ington and the capital cities of the principal nations of the world. In connection with our edi-  
torial, scientific and Patent Law Library, and record of original cases in our office, we have  
other advantages far beyond those which can be offered home inventors by other Agencies. The  
information accumulated through long and careful practice before the Office, and the frequent  
examination of Patents already granted, for the purpose of determining the patentability of  
inventions brought before us, enables us often to give advice which will save inventors the  
expense of applying for Patents upon inventions which are not new. Circulars of advice sent  
free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

## No Drouths! Sure Crops!

**READING RANCH,**  
Shasta Co., Cal.

**Good Land!**  
**Sure Crops!**  
**HEALTHY CLIMATE!**  
**Prices Low. Terms Easy.**

**TITLE PERFECT.**

The Reading Ranch, in the Upper Sacramento Valley, originally embracing over 26,000 acres of choice grain, orchard and pasture land, is now offered for sale at low prices and on favorable terms of payment, in subdivisions to suit purchasers.

The ranch was selected at an early day by Major P. B. Reading, one of the largest pioneer land owners in California. It is situated on the west side of the Sacramento River and extends over 20 miles along its bank.

The average rainfall is about 30 inches per annum, and crops have never been known to fail from drouth. The climate is generally healthy. The near proximity of high mountain peaks give cool nights during the "heated term" which occurs in our California summers. Pasture, wood and good water are abundant. The tillage land is mostly level, with complete drainage. Figs, Grapes, Peaches, Prunes, Almonds, English Walnuts, Apricots, Currants, Berries and other common fruits can be raised with success on most of the tract without irrigation. Also, Alfalfa, Vegetables, Corn and all other cereals ordinarily grown in the State.

The soil throughout the tilled portions of the ranch proves to be of great depth and enduring in its good qualities. It is quite free from foul growth. The virgin soil among the large oak trees on the bottom land is easily broken up and cultivated.

The title is U. S. patent. Prices range principally from \$5 to \$30 per acre.

The California and Oregon railroad traverses nearly the entire length of the tract. There are several sections, stations and switches, besides depots at the towns of Anderson and Reading, all of which are located within the limits of the ranch.

The Sacramento River borders the whole tract on the southeast. Its clear waters are well stocked with fish. Good hunting abounds in the surrounding country.

Producers have a local market, which enhances the value of their produce. The railroad transportation route is level throughout to San Francisco. A portion of the land is auriferous and located near rich mines now being worked. Land suitable for cattle in colonies can be obtained on good terms.

Town lots are offered for sale in Reading, situated on the Sacramento river, at the present terminus of the railroad. It is the converging and distributing point for large, prosperous mining and agricultural districts in Northern California and Southern Oregon. Also, lots in the town of Anderson, situated more centrally on the ranch. Lots in both these towns are offered at a bargain, for the purpose of building up the towns and facilitating settlement of the ranch.

Purchasers are invited to come and see the lands before buying here or elsewhere. Apply on the ranch, to the proprietor.

**EDWARD FRISBIE,**  
Anderson, Shasta Co., Cal.

Location of Shasta County.

Shasta County lies not far from midway between the two most important ports on the Pacific shore, i. e., San Francisco and Portland-Oregon, and directly on the route from Mexico to British Columbia. The town of Redding, at present, and probably for years to come, the head of railroad transportation on the California side of the mountains intervening below Oregon, is distant from San Francisco by railroad (via Vallecjo) 255 miles; from Sacramento City, 169 miles; from Marysville 117 miles.

Persons thinking of buying or renting land will not likely regret a camping or excursion trip to this upper Sacramento country.

**LAND FOR SALE OR RENT IN SUB-DIVISIONS.**

## EMERY WHEELS and GRINDING MACHINES.

## DuBOIS' Automatic Quicksilver Feeder.

A machine for feeding quicksilver to the mortars of GOLD MILLS. It is so connected to the cam shaft, that each revolution of the large ratchet wheel, which can be regulated to revolve once in one, two, three or four minutes, as desired, dips a small cup into a reservoir of quicksilver, and by a mechanical movement, empties the contents into a pipe leading down to the mortar, supplying an exact quantity at regular intervals, superseding ordinary hand-feeding, which is of necessity subject to great irregularity, and liable to neglect. It renders the amalgamation of all the gold in the pulp equally certain and perfect. Price complete, \$100.00. Send for circular.

**P. C. DuBOIS,**  
18 Fremont St., S. F.

## NEW REVISION AGENTS WANTED. NEW TESTAMENT.

## A Curious Amalgamator.

An inventor named Dickson, of Spearfish City, Dakota, has devised the amalgamator shown on this page. The apparatus has a supply-hopper and a number of downward and upward passages connected with scroll-shaped receptacles, arranged in such a position that the pulp from the stamp mill is spread out in thin sheets and the current caused to revolve with great velocity, whereby the gold and quicksilver are brought thoroughly and intimately into contact and remain in the receptacles, while the current carries off the debris.

There may be more or less receptacles. The pulp from the mill is to be fed to the hopper in a regular and constant stream, and running down the first port, it will be spread out and caused to flow with great velocity, in consequence of the small comparative size of the port, and the stream entering the first receptacle, to which the quicksilver has been previously supplied, is caused to whirl around, and the gold and mercury are brought intimately in contact throughout the mass in every port, and the amalgamation facilitated.

The stream will rise in the ascending port, and from thence over and down to the second receptacle, where the operation is similar.

The ascending ports are larger than the descending ones. The velocity is just sufficient to carry off everything that is of less specific gravity than gold or quicksilver. The receptacles are each to be supplied with quicksilver, and the number of the series and the size of the parts are to be such that nothing of value shall pass out the discharge opening.

To facilitate the regulation of the velocity, the inventor perforates the walls of the last descending port and puts plugs in the holes, as shown. By removing the plugs or a number of them, the ejection in the ports will be diminished and the velocity of the current checked. Little or no mud will be left in the receptacles to accumulate and prevent contact of the gold and quicksilver. The velocity of the current will carry off the heavy as well as the light mud.

## Filing Mining Claims on Sunday.

Some time since an adverse claim to a mine in Nevada, patent for which had been applied for, was rejected by the Commissioner of the General Land Office, for the reason that the adverse claim was not filed within the time set by law. It was one day late; that is, it was filed on a Sunday, and the Commissioner held that "officers are not expected nor required to transact official business after office hours, nor to have their offices open for the transaction of business on Sunday." The claim was therefore considered as filed on Monday, which was a day too late to cover the law. That is, the 60th day of publication fell on a Sunday, but at 10 P. M. of the day before the adverse claim was presented to the Register, with the fees for filing, but he refused to take the claim or fees. On the next day (Sunday) the claim and fees were tendered to the Receiver of the Land Office, and he took them.

When the Commissioner of the Land office decided that the Sunday filing was illegal, the claimants appealed the case to the Secretary of the Interior, Hon. Carl Schurz. He reversed the decision, holding that in the absence of a law to the contrary, an adverse claim may be filed on Sunday or out of office hours, if the local officers are willing to receive it; though they are not required to receive adverse claims or transact other business except during regular office hours. He found no law of the United States prohibiting them from transacting such business on Sunday if they chose to do it. Nor could he find any law of the State of Nevada which prohibits the transaction of ordinary business on the Sabbath day.

CALIFORNIA has been in American possession but 34 years, and its exports and imports are this year more than twice as great as those of the 27 States and two Territories which compose the Mexican republic, though California's population is less than one-twelfth and its area not more than one-fifth of hers.

## Academy of Sciences.

### Wrangel Land and Arctic Exploration.

At the meeting of the California Academy of Sciences on Monday evening, a reception was tendered to Lieut. Roht. M. Berry, of the U. S. steamer *Rodgers*, and his staff of officers, belonging to the U. S. Arctic Exploring Expedition dispatched by Congress to the relief of the *Jeanette*.

The seating capacity of the hall was too limited for the audience, and many persons were compelled to stand. Lieut. R. M. Berry, Ensign H. M. Hunt, Col. W. H. Gilder, *Herald* correspondent; Assistant Surgeon Costello, Assistant Engineer A. V. Zane, Past Assistant Surgeon M. D. Rodgers, of the relief ship *Rodgers*, and Capt. Howgate, the organizer of two Arctic expeditions bearing his name, occupied

DICKSON'S AMALGAMATOR.

seats on the platform. President George Davidson occupied the Chair. After some unimportant preliminary business, a highly interesting and complete paper on evidences regarding the discovery of Wrangel Land, and the course pursued by the exploring ship *Jeanette*, was read by Charles Walcott Brooks.

Prof. Davidson read a paper prepared by James Gamble, retiring General Superintendent of the Western Union Telegraph Co., advocating the use of a 20-lb. per mile steel wire for the maintenance of telegraphic and telephonic communication between the sledge parties sent out

the Navel Relief Board have profited materially in making up the route by which we are to go out. It will be followed as strictly as practicable. In regard to the experiments with wire, I shall be very happy, indeed, to make those, testing them in every way. I think, however, that it will be very difficult on extended sledge journeys, for the reason that we have an immense weight to haul. When you speak of additional dogs to haul the wire, you must take into account that they will require additional food and additional material on board ship. We find that all Arctic ships, when starting from port, are overloaded with material. The *Jeanette* went out of here loaded to the water-line. I am fortunate in having a larger ship, but she is now crowded, and will be overcrowded when we get the other stores. It will be very difficult to take much wire. When you take that you must give up coal and other things which are very material. I also would be very happy to make those experiments with the signals that were referred to. I don't think it will be necessary

to refer to my journey as we have had it explained as far as I can explain it myself now, because after reaching Wrangel Land I shall have to be guided by circumstances. There I shall find a new country that has not been explored, and after reaching there I shall have to form new plans."

W. H. Gilder, who goes with Lieutenant Berry as Pay Clerk, and who was a member of the Schwatka expedition last year, presented the Academy with a piece of hammock, evidently part of a fishing pole, one of the relics of the Franklin expedition, of whose wrecked ship

HASKINS' PATENT DITCHING AND EXCAVATING PLOW.

and the winter headquarters of the Arctic expedition. We give this paper in full in another column.

In reply to an inquiry from Professor Davidson, Lieutenant Berry said he did not consider the claim of Captain Dollman to the discovery of Wrangel Land well founded, as he had waited for fifteen years before speaking of it.

Captain Howgate referred to two Arctic expeditions which had been sent out by himself, and to a third which would leave Newfoundland this year in charge of Lieutenant Greeley, and which was outfitted by the War Department. The latter, he said, carries among other supplies a telegraph wire, flags and candle bombs. Lieutenant Greeley is instructed to look out for the *Jeanette*, as it is possible Lieutenant DeLong and his associates may be carried by the Arctic currents in the North Atlantic.

Lieutenant Berry, Commander of the relief ship *Rodgers*, was then introduced, and spoke as follows:

"I wish to take this occasion to thank this Academy for the information by which I and

and records Lieutenant Schwatka went in search.

KERN COUNTY MINES.—A correspondent of the Press sends us the following items from Sumner, Kern county: "The men at Kernville who have got the Big Blue mine and mill have worried along the past year with men on tribute. Lately, the miners went through the foot-wall of their Sumner mine and struck a four ft. pay vein that will run \$35 per ton; so 40 stamps are running right along. This makes flush times at Kernville. The Pinto or Lone Star mill is to be torn down and removed to San Francisco for Parke & Lacy. A company have bought a small mine on Pinto mountain, and are working Chinese miners on quartz."

It has been thought that more satisfactory investments could be made in developed mines than in prospect holes, but many investors think that this is wrong, and that prospects which show good ore and true fissure veins, are better than developed mines.

## New Ditching Plow

Alphonso Haskins, of Davisville, Yolo county, has recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, an improved ditching and excavating plow which is illustrated on this page. The improvement consists of a shoe which is fitted to run upon the bottom of the trench or excavation, and has a suitable point for digging or loosening up the soil. Peculiarly shaped shares, having a narrow, flat front portion, extend upward and backward at an incline so as to carry the earth above the level of the ground, and from this point the shares curve outward so as to throw it away from the trench on each side.

The plow has a coulter-wheel as shown, arranged to raise or lower by hinged or pivoted standards. The plow standard is suitably secured to the beam and the shoe is bolted or fixed to its foot. This shoe is of considerable length, narrow and flat upon its bottom, so as to run upon the bottom of the trench and smooth and level it similar to the action of a plane.

The point is formed or secured upon the front of a bar or plate, which has its upper end secured to the standard and extends down to the front of the shoe, thus forming a support for the shares, which may be bolted to it.

The shoes conform to the outline of this bar, and are made narrow and flat at their lower front end so as to receive the earth from the point, having about the same width. This flat surface extends upward and backward, widening slightly up to the point where the shares begin to curve outward. The surface of this portion is nearly in a straight line from the point, and brings the earth up to the flaring portion of the shares, which then take it and throw it outward upon each side, and entirely clear of the trench.

By this means Mr. Haskins is enabled to form trenches of any desired depth, having a perfectly smooth flat bottom, suitable for laying cement or other pipes. This plow is especially adapted for the formation of trenches in which irrigating pipe is laid, when said pipe is formed and laid at one operation, from the plastic material. It can also be used in making mining ditches, etc.

## Ore Sampling.

The ore sampling works of Hofmann Bros., 415 Mission street, of this city, have of late been displaying an unusual activity in crushing and sampling ores which they receive from all parts of the Pacific slope, Alaska, Mexico and Central America. The most remarkable ore they ever received was a lot, the other day, from Chihuahua, Mexico, consisting of five tons ranging from \$5,000 to \$15,000 per ton in value; in fact it contained so much native silver that the precious metal clogged up their machines and necessitated the picking out of the largest pieces of solid silver, some of them weighing 11 lbs. and over. It certainly was a wonderful sight to admire, these beautiful specimens in their different formations, and almost seemed a pity to see them committed to their powerful crusher to be shivered to fragments. A beautiful specimen of this ore may be seen at the State Mineralogical Museum under the charge of Mr. Hanks and also at the office of Mr. Jno. M. Adams of this city, who has charge of the ore.

Other high-grade ores are constantly worked at these mills. The more conspicuous among them are the Silver King Concentrations and monthly shipments from the Jocuistita mine, Mexico, of Mr. J. B. Haggin, of this city. Owing to the increase in their business, the works have recently been enlarged, and, to fill a long needed want, one of Mr. M. B. Dodge's concentrators has been set up where low graded ore, which are otherwise almost valueless, can be concentrated and made to yield quite a revenue to their owner.

Persons interested in ores and mines generally are invited to inspect their works where all desirable information will be cheerfully furnished.

SENATOR JOHN F. MILLER will return to San Francisco in July.

## CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

### The Owens River Country.

Bishop's Creek and Plute Mining Districts.

**EDITORS PRESS:**—After many years of silence I wish to renew a correspondence with your paper, and will try to make it regular, so that your readers may keep themselves posted in regard to this portion of our State. Eighteen years ago, when your correspondent first came to Owens river, the country presented a far different aspect from its appearance now, upon his return. In 1863 but one farmhouse could be found in the valley; now there is hundreds. Then the adjacent mountains were being run over by prospectors in search of hidden wealth, and little attention was paid to farming; a few mining towns sprung up, only to disappear when capital was withdrawn from their support, and other towns appeared as soon as the fast growing agricultural interests of the valley required them.

But a new era is about to dawn, apparently, upon this quiet valley. Rich mineral-bearing veins have been known for years to exist in the White Mountain range, east of and opposite Bishop creek; and many ledges have lain idle for years, apparently waiting the advent of improved machinery and cheaper freight transportation. That time has now arrived, and many mine owners are making earnest efforts to develop their mines and place them in proper shape.

#### The Discovery Last Fall

Of a very valuable gold mine, which is now proving to be an extensive one, gave a new impetus to the mining industry. This mine has been recently sold. What the consideration is I have not learned. The parties purchasing are from Bodie. I have no doubt their intention is to erect a mill and commence the working of ore as soon as possible, as the mine is easy of access, the facilities good for either water power or steam, and the ore free-milling. Probably a better piece of mining property cannot be found unoccupied on the coast.

They are down upon the ledge 56 ft. At the surface the ledge was five ft. in width, at the bottom of shaft is seven ft. wide, having increased in width gradually from the surface. Eighteen tons of ore, taken from the shaft, and worked in three Mexican arrastras, yielded 66 ounces of gold, or a little over \$1,000. Much of their rock will assay \$400 or \$500 per ton, and some samples will go into the thousands. Two mining districts have been formed, one, the

#### Bishop Creek District,

Lies east of town, and the mines lie within a distance of from six to twelve miles.

Some 50 locations have been made, and probably 10 or 12 of these are being worked upon, and already showing good prospects.

From samples brought to town by different parties, I find that the ore consists of a great variety. Some free gold ores, some silver sulphurets, and chlorides, and others of carbonates and galena. The ore, as a class, is what might be called medium in value, neither a high nor a low grade, usually assaying from \$60 to a \$100, some samples reaching \$300 or \$400.

At a distance of 12 miles from town, to the northeast, another district has been organized, under the name of the

#### Plute Mining District,

Where some 30 locations have been made.

This district lies wholly in the county of Mono, and adjoining the northern line of Inyo. An old mine has recently been re-located, and the present owners are opening it up in good shape. This mine was first located in 1857 by a party of surveyors, and again located in 1863. In 1864 an incline was sunk to the depth of 75 ft. on a spur to the main ledge, but when capital was withdrawn from Aurora, Owens River suffered in like manner, and the mine, like many other valuable properties, relapsed to the ownership of the Government. The value of the mine was scarcely known, and only the high grade of some of the ore induced the present owners to attempt its development, and they are meeting with most excellent success.

The main ledge is very large, cropping out holdly for 2,000 ft. in length, with an average width of 12 ft. It is situated entirely in brown porphyry with birdseye and light gray porphyry adjoining the ledge and forming its walls.

They have several adjoining claims, several of which are spurs to the main ledge, and others parallel veins, some of which carry a large percentage of gold. The character of the ore is chiefly a gray sulphuret of silver, with chlorides and oxides. Their assays, taken from nine different portions of the ledge, average about \$150, varying from \$38 to \$300 per ton. At present they are at work on the main ledge, about midway of the croppings, and are down 20 ft.; have a width of ledge of 10 ft., 6 ft. of which is good milling ore, with an average assay of \$160. This mine is situated in one of the most favorable localities. Water can be conveyed by pipe, a distance of two and a half miles, and 50 inches or more if needed can be delivered upon any portion of the mine. A mill can be erected there and Burleigh drills used in mining. I have visited the ground and am of the opinion that there is ore enough to justify the erection of a 40-stamp mill.

There is an abundance of nut pine timber above the mine, and easy of access. This mine, like the one previously mentioned, is easy to reach from the valley by a good wagon road already graded and in constant use within a mile of the mine.

#### The Prospects of these two Mining Properties

Are now the constant theme of conversation upon the street, and the farming town of Bishop Creek is fast becoming transformed into a veritable mining camp. Almost daily we can see loads of provisions, mining tools and supplies, leaving town for the mines.

Another topic also is becoming a common subject of conversation. It is the universal belief that the railroad that is now running to Hawthorn will eventually enter Owen's valley, and run thence to Mojave. This, it is predicted, will be accomplished within two years.

The agricultural interests of Owens Valley is in a very prosperous condition, and everything denotes good crops and speedy sales. The mining camps east of here, Gold Mountain, Lida Valley, Montezuma and Deep Springs, depend upon Owens Valley for much of their supplies, of hay, grain, flour, etc., and as those camps are awakening into renewed life, their demands will be greater upon this mountain storehouse, and all parties will derive benefit from the revival of trade.

Owens River and the entire surrounding region is destined from this time forward, to rank as one of the most prosperous portions of the Pacific coast. Large capital is finding its way into this section, and small capital and population is sure to follow.

CONCORD.

Bishop Creek, May 28th.

### Copper Smelting—Its History and Processes.—No. 9.

[By HENRY HUBBARD VIVIAN, M. P.]

#### Take the Case of Antimony,

It will be seen that the one-thousandth part converts first-rate "best-selected" copper into the worst conceivable, so had as to be only fit for casting as brass; short in fracture and a bright yellow. That one four-thousandth part makes it unfit for anything but inferior brass purposes, below the quality known as tough ingot. That one eight-thousandth part reduces it from "best select" to tough ingot quality, and that one sixteen-thousandth part sensibly deteriorates the quality. You will observe that one-thousandth part of nickel, cobalt, bismuth, arsenic and phosphorus reduces "best selected" to tough ingot quality.

White nickel and arsenic in combination, and mixed in the proportion of one five-hundredth, make copper unfit for brass.

The last trial shows that two substances in combination may often produce a far more hurtful effect than either of them separately. I am indebted to Mr. A. S. Morry for this latter suggestion.

One curious inquiry arises, namely: How is it that any given

#### Admixture of Another Metal

With brass causes it to change its character, if that admixture is infinitely small? I remember well that some 35 years ago, just after I had finished my synthetical trials, I had a conversation with the late Mr. George Frederick Muntz, the inventor of yellow metal, who was probably the best brass manufacturer of his day, upon this point, namely, the brittleness and yellow color of bad brass. He told me that he could not explain it, and that, although he had sought an explanation from some of the best chemists of the day, not one of them had been able to give him a satisfactory reply. I was very young at that time, and felt proportionately proud of being able to give him such an explanation as he at once admitted to be satisfactory. It was as follows, and I believe it is contained the true cause of brittleness and toughness in all metals: During my experiments, I had observed a case—I think it was the admixture of a certain amount of tin with brass, in which the fracture was rough, coarse and mottled, drab and yellow. Upon close examination, I discovered that this appearance was due to the metal being composed of large crystals. I found that the mottled appearance was due to some of these large crystals being broken through, while others had separated, having their facets bright and unbroken. The former presented a drab appearance, while the latter, reflecting back the light, were bright yellow. I at once saw that the brittleness and yellow color of bad brass were due to the crystallization being extremely small, so that each crystal, being very minute and having an existence separate from its neighbor, parted without fracture, and, possessing unbroken facets, reflected back a yellow light like polished brass. This is further confirmed by the well-known fact that if, instead of allowing bad brass to cool slowly, you quench it in water and thus change its crystallization, it is no longer brittle and yellow when broken. When a metal forms in long crystals in cooling, it is sure to be tough; but when the crystals are fine and sand-like, then it must be brittle. I believe this same law applies to all metals.

Now, having spoken so much of bad copper, I may naturally be asked how to make good and

#### How to Avoid Making Bad Copper.

I fear my answer can neither be complete nor satisfactory; but I may at least contribute something toward the solution of the various problems involved in this difficult question.

My first advice is; to do your best to deter-

mine beforehand the quality of the ores you have to treat, and never to mix a had ore with good ores. I speak in the plural because it is surprising how small a quantity leavens the whole lump.

My next advice is, that, when you have once got impurities out of your smelting mixtures, never put them back again. One of the greatest improvements we have ever effected in copper smelting is never to allow roaster or refinery slags to be melted in the metal furnaces, but to treat them by themselves. It is true that by so doing you lose the advantage of their oxidizing action, but that is a small matter compared with the perpetual addition of deleterious substances to your mixture.

Then I would say, avail yourself of the old "best selected" or "regule" process where your material contains impurities which pass into the copper bottom formed in that process. All the foregoing recommendations refer to copper material in course of treatment, not to copper itself when once made. What are we to do with bad copper? My answer is, that that is a question of degree. Copper may be so bad as to be only fit for casting as brass. In that case, make up your mind to sacrifice a pound or two per ton, instead of expending perhaps twice as much in trying to make it better. It is no doubt difficult to make had metallic copper into good, but by our present improved methods much may nevertheless be done. I think about the year 1851 or 1852, I accidentally hit upon a plan of improving metallic copper, which has stood us in very good stead ever since. I was experimenting on the separation of nickel and cobalt, contained in some ores we were then receiving, by the admixture of arsenic, and I naturally managed to get an excessive quantity of arsenic into the copper so experimented on, which did not improve its quality. Arsenic was retained by the copper through the refining process, and was present in the tough cake copper sent to the mills. This copper was tried by rolling in the usual way, and the trials, which were of course extremely bad, were laid out for my edification and inspection on the iron plates of the mill floor. To my surprise, in turning them over, I saw that the iron plates on which these trials had cooled were as white as if they had been whitewashed. I saw at once that arsenic had been distilled out from the body of the copper while in the annealing furnace at a red heat, and had continued to pass off even while the copper was cooling on the mill floor. It occurred to me that what had happened accidentally might be made available systematically, and I caused had blistered copper to be submitted to a slow, constant, long-continued heat in the roaster furnace without melting it until it was desired to withdraw the charge. To this process I gave the name of "dry roasting." I see that Dr. Percy, on page 380 of his work of 1861, talks of "dry roasting" practiced in former days, as described to him by an old smelter; but that was evidently a wholly different matter, depending on the exposure of pigs of regulus during the greater part of the process of roasting to a less degree of heat than sufficed to melt them, and the roastings were repeated often three times until "blister" copper was obtained. My plan does not come into operation until after "blister" copper is obtained. We always roast our regulus down very slowly; and I do not see how the process above described could have been carried out, since white metal melts at a very low temperature, and parts easily with its sulphur, setting free metallic copper; how the pigs are to be withdrawn from the furnace often three times without melting, I fail to see. I have heard of the frequent calcination of regulus and remelting, practiced in olden days, having the effect of improving quality, and I think the old smelter must have alluded to what was done at some works even in my time, namely, calcining ore-furnace metal only sufficiently to produce "blue" or "red" metal, and then calcining again before producing "white metal." This was called coarse and fine metal molting, but had no relation to the process I have described, which, I believe, were the first to put in practice. I do not even know that it is used at any other works at this moment. The effect of this "dry roasting" of blistered copper is very marked; we can bring up copper which, if refined without dry roasting, is so brittle that it is reduced almost to powder in passing through the rolls, to a tough quality fit for all ordinary copper uses. This is effected by keeping the pigs of blistered copper at a good red heat in a roaster furnace for 24 hours, then melting and tapping in the usual manner; this process is again and again repeated until the desired degree of quality is attained. I have tried the effect of carbonizing, or, perhaps I should rather say, de-oxidizing the copper before tapping, believing that volatile impurities would be more readily sublimed when in a metallic state, but no very sensible difference resulted. The process ceases when the copper is melted.

Another and more recent system of improving the quality of metallic copper is the addition of niter and lime in the refining furnace; to whom the first suggestion is due, I know not; it has been kept, and is to this day, one of those profound secrets which everybody knows and avails himself of when it suits him, without imparting it to his neighbor. This process is as follows: 25 lbs. of nitrate of soda and 75 lbs. of lime are intimately mixed and thrown on the charge of copper in the refinery after the slag has been removed; the charge is then poled or "flamed" for half an hour, and then the slag is skimmed off. If the first operation does not sufficiently improve the copper, it is repeated again and again. We have found that the qual-

ity of copper is decidedly improved by this system, both for brass and copper uses; but I have reason to fear that it is attended with some loss of copper, and it is also expensive if often repeated.

Before taking leave of copper-producing industries, I ought briefly to mention

#### Two Most Important Systems

By which copper is extracted from pyrites rich in sulphur and poor in copper by the wet way; the one I have already alluded to, namely, the system adopted in Spain at the great works of the Rio Tinto and Tharsis companies and at those of Messrs. Mason & Barry; the pyrites is placed in large heaps in the open air; these are set on fire by a layer of wood placed beneath, and continue to burn for many months; the copper contained is partially converted into sulphate, the burnt ore is then washed with water in vats, whereby the sulphate of copper, being soluble, is extracted; the liquor is then run over iron, whereby the copper is precipitated and collected in the metallic state. The residua of this lixiviation are then deposited in immense heaps with a certain proportion of raw pyrites, water is laid on, and the remaining portion of copper is said to be completely washed out in some six years; the liquors issuing from the base of the heaps are, of course, collected, and the copper they contain is precipitated in the manner described above.

The other process is that of Mr. Henderson for the treatment of the burnt pyrites obtained from the kilns of sulphuric acid makers. I have never seen this process, and it would therefore be improper that I should do more than mention it as a process which has proved eminently successful for the treatment of that material, extracting the copper, I believe, very completely and leaving a residue composed of almost pure oxide of iron, valuable in iron smelting. I am informed that the burnt residua of the kilns are calcined with salt so as to convert the copper into a chloride, which is partly volatilized and condensed and partly obtained by lixiviation—first with water and subsequently with dilute hydrochloric acid.

(CONCLUDED.)

### Rehearing on Mineral Land Cases.

In January 1881, the Commissioner of the General Land Office decided certain lands to be agricultural, dismissing the application of mineral affidavits for a new hearing. The latter subsequently asked for a review and modification on the grounds that the land is mineral and that they should have an opportunity to submit testimony to prove the fact.

At the original hearing no one appeared for the mineral claimants. Subsequently affidavits were filed alleging the land to be mineral. At the latter date the General Land Office had no knowledge that the case had been received and accordingly directed a hearing to be held. This was subsequently revoked, the case taken up for examination and the decision above referred to rendered.

The reason assigned by the mineral affiant for neglecting to attend the hearing already had was that they were peculiarly unable to appear.

Rule 76 of the rules of practice provides that rehearings will be allowed in accordance with legal principles applicable to motions for new trials at law.

Pecuniary inability to attend a former trial would not be considered in the courts sufficient ground for allowing a new trial and consequently cannot, under the rule, be looked upon as sufficient ground for allowing a rehearing. Moreover, it is not necessary for a claimant to appear personally at the original hearing; he could do so by counsel.

Also under rule 23 a claimant can apply to have taken the deposition of their witnesses, so that the personal attendance of witnesses is not necessary.

Courts do not allow new trials for causes which proper diligence would have avoided.

Rule 78 requires motions for rehearings to be accompanied by an affidavit that the motion is made in good faith and not for the purpose of delay.

Rule 80 provides that no officer shall entertain a motion in a case after an appeal has been taken from his decision.

The Commissioner, in deciding the motion for a rehearing, says: "As this motion does not allege sufficient grounds for allowing a rehearing, as it is not accompanied by the requisite affidavit, and was made after my jurisdiction to entertain a motion had ceased by reason of the appeal, and as no new discoveries or developments are alleged, the rehearing cannot be allowed." A word to the wise is sufficient, or ought to be, in mineral cases as well as all the other affairs of life.

MINING as an industry, is second to none except agriculture, which without the produce of mines would be much less in the aggregate. The one acts as a stimulant to the other, inasmuch as the products of the agriculturist, as they enter into the necessities of increasing population and commerce, enlarge the demands of the precious metals.

THE mines of Canada and Newfoundland are at last receiving considerable attention. They are drawing to their aid a large amount of capital, as well as the very necessary adjunct, practical mining experience, for the development of their vast mineral resources, both from England and the United States.

## MECHANICAL PROGRESS.

## Iron and Steel.

Good iron and good steel should be of close, uniform grain, bright gray color, more or less of silky fiber. The dull, earthy color, loose texture and unequal grain or blackish fiber are bad signs. Steel fractures are either granular, crystalline or fibrous. Wrought iron fractures are crystalline or fibrous, with intermediate conditions. Wrought iron, if broken suddenly, will show a crystalline fracture, while if broken gradually it will appear fibrous. If it is good iron and suddenly broken, the grains will be fine, bright and uniform. Poor iron suddenly broken shows large, coarse, dull grains. Good iron, gradually broken, shows fine, close fibers, while poor iron gradually broken, shows fibers that are coarse and open.

In comparing irons, all the samples should be broken, or bent, or twisted exactly in the same way, as the mode of testing influences the appearance of the fracture. The pieces compared must be of the same shape and size, and the treatment just the same in every respect; otherwise the tests will be of little or no account. If it should be desired to make the fracture of a piece of iron appear entirely crystalline instead of entirely fibrous all that would be necessary would be to so alter the shape of the specimen as to render it more liable to snap suddenly, or to make it harder by any treatment, or to apply the strain suddenly, so as to make it snap quickly. In the case we show the fibrous structure, the threads are gradually drawn out and are seen externally. In the other, where they are snapped by sudden strain, they are broken square across, and their ends are seen, giving the granular appearance.

When the steel is twisted, the results depend upon the manner of testing, as well as upon the nature of the material twisted. Slowly applied strain gives a silky fibrous structure, while quick breaking gives a granular structure. In both cases the fineness of the fiber or of the grain depends upon the fineness of the material. The color of steel fractures is light pearl gray, the quality having something to do with the shade; but the granular fractures are not lustrous like those of iron.

There are many tables published, giving the strength of different materials used in construction. From these tabulated results of tests that have been made, designers and manufacturers lay out and calculate the dimensions of various machines and structures, allowing a factor of safety, varying from 3 to 6 and even 12, according to the uses and abuses to which the material is to be subjected. But it must not be supposed that these figures are infallible and invariable. This is far from being the case. These figures represent, at best, the mean of several carefully conducted experiments on certain samples, which may or may not be average specimens, and generally are specimens of more than ordinary excellence. In some cases, notably in cast iron, the variation from the average is very great, so much so that in some cases it would absorb all the factor of safety. Bear in mind that these figures are good only as averages.

But there is one thing that is very seldom thought of, and that is, that figures good for one size and shape of plate, or bar of a given material, are not good for other sizes or shapes of the same material, tested under the same conditions. It is found that if tests are made of a number of bars of iron, from any make, made from the same stock, by apparently the same process, and with apparently the same care, the tensile strength per square inch will vary greatly.

The proportion of the increase, in tensile and elastic limit varies just in proportion with the decrease of the percentage of areas of the bar and of the pile.

The inference from all this is that tests made from one size must not be taken as infallibly showing the strength of any other size, and that in the matter of bridge and boiler construction it is best that the tests be made upon equal sizes taken from stock.—*Exchange*.

## The Strength of Wrought Iron Columns.

In a paper contributed a short time since to the American Society of Civil Engineers, Mr. G. Bouscaren has given some interesting results of experiments made on different forms of wrought iron columns, these being of a variety of sections, including hollow hexagonal columns, hollow squares with solid plate and with lattice sides, the well-known Phoenix columns, and H sections. One of the objects of the experiments was to determine the relative trustworthiness of the well-known formulae of Gordon and Rankine for hollow columns, and the results Mr. Bouscaren considers to be in favor of the latter. In the case of the Phoenix posts, the extreme values of the constant  $a'$  in Rankine's formulae were 49,400 and 41,100, a variation of 17%, while in the case of square closed columns with flat ends, the extreme values of  $a'$  were 39,800 and 38,300, a variation of 4% only. Other conclusions arrived at were that iron of the highest modulus does not necessarily make the strongest columns, and that in built-up columns it is highly essential to insure thorough connection between the parts in order to guard not only against lateral flexure of each part but also against relative longitudinal move-

ment. Mr. Bouscaren further states that his experiments bear out Rankine's assumption that in dealing with columns with hinged ends, the value of  $a'$  should be taken as double that used for columns with flat ends.

## Value of Experiments.

It is singular how significance is given to trifling experiences by the recorded or related experiences of others, and how much, that is of importance in our lives, would be lost in its lesson, but for cumulative evidence, or at least additional testimony. And much of this experience is wasted because of lack of mediums for extending it, or for giving its results.

Probably no department of human knowledge is so entirely dependent upon experiment for its advance as mechanics. This is seen in the progressive trials for ultimate success in large engineering works, as the boring of tunnels, the construction of viaducts and bridges, the overcoming of natural, topographical and climatic obstacles shown in the construction of our trans-continental railroads.

In engineering (mechanical) there is much the same record of trial, test, experiment and gradual progress—the progress depending, however, on the success of the experiments. There is not a successful steam engine builder in the country but who must trace success up through tests and experiments; and there is no one who can properly and honestly assume that he has the typical universal engine, adapted to all sorts of work and all circumstances of location. Such absurd claims are sometimes made, but it requires but a little consideration to show how baseless they must be.

Repeated experiments have been required to designate the proper type of hoisting-engine for mines; experiments, some of them very costly, have been made to find the most effective pumping engine; and the list might be made to include engines for wood working, for wool working, for cotton working, for the preparation of materials for manufacturing processes, and for many other purposes. And yet, after all the tests, after all the experiments, there is a great difference in the engines employed for these purposes in different localities and under varying conditions, although the difference in their results may be but slight, and their respective owners may be equally satisfied with their performances.

In shop mechanical work there is also the need of continual experiment, resulting in better adaptation of means to the end, in a better type of machinery and tools for general use; and, also, in a separation and division that gives us special tools and machinery for special objects and intentions. This dependence on experiment is forcibly shown in the necessity for draftsmen and pattern makers. They are among the most important of our workers in mechanics. They are continually originating, and, in some sense, perfecting types of tools and modifications of machines, so that the mechanic who should indulge in a Rip Van Winkle sleep of a decade would find himself in a new mechanical world.

The moral to be drawn from these premises—the correctness of which no "live" mechanic can deny—is that the mechanic art has not yet arrived at that state of perfection when set rules and unvarying law can take the place of empirical test and experimental trial. The progress of mechanical, practical knowledge is in the shop, and not in text books, nor in treatises on well understood mechanical laws.—*Boston Journal of Commerce*.

## Mechanical Terms.

W. Barnet Le Van, gives in the *American Machinist*, the following definitions of a few mechanical terms which are commonly used, but too often only vaguely understood:

Dynamics is the science of that branch of mechanics which treats of force in motion, power and work. It comprehends the action of all kinds of machinery; manual and animal labor, in the transformation of physical work.

Element is an essential principle which cannot be resolved into two or more different principles. The simple physical elements of dynamics are force, velocity and time, and the functions of those elements are power, space and work.

Function is any compound result or product of two or more different elements. A function is resolved by dividing it with one or more of its elements.

Force is any action which can be expressed simply by weight, and which can be realized only by an equal amount of reaction, and is the first element in dynamics. All bodies in nature possess the incessant virtues of attracting and repelling one another, which action is recognized as force.

Velocity is speed or rate of motion, and is the second element in dynamics.

Time implies a continuous perception, recognized as duration, or that measured by a clock, and is the third element in dynamics.

Power is the product of force and velocity; that is to say, a force multiplied by the velocity with which it is acting, is the power in operation. Power is the differential of work or any action which produces work, whether mental or physical. Power multiplied by the time of action is work—work divided by time is power.

Work is the product obtained by multiplying together the three simple elements, force, velocity and time.

## SCIENTIFIC PROGRESS.

## Faraday's Electro-Chemical Researches.

The majority of Faraday's own researches were connected, directly or indirectly, with questions regarding the nature of electricity, and his most important and most renowned discoveries lay in this field. The facts which he has found are universally known. Nevertheless, the fundamental conceptions by which Faraday was led to these much admired discoveries have not been received with much consideration. His principal aim was to express in his new conceptions, only facts, with the least possible use of hypothetical substances and forces. This was really a progress in general scientific method, destined to purify science from the last remnants of metaphysics. Now that the mathematical interpretation of Faraday's conceptions regarding the nature of electric and magnetic force has been given by Clerk Maxwell, we see how great a degree of exactness and precision was really hidden behind his words, which to his contemporaries appeared so vague or obscure; and it is astonishing in the highest degree to see what a large number of general theories, the methodical deduction of which requires the highest powers of mathematical analysis, he has found, by a kind of intuition, with the security of instinct, without the help of a single mathematical formula.

The electrical researches of Faraday, although embracing a great number of apparently minute and disconnected questions, all of which he has treated with the same careful attention and conscientiousness, are really always aiming at two fundamental problems of natural philosophy: the one more regarding the nature of physical forces, or of forces working at a distance; the other, in the same way, regarding chemical forces, or those which act from molecule to molecule, and the relation between these and the first.

The great fundamental problem which Faraday called up anew for discussion was the existence of forces working directly at a distance without any intervening medium.—*Prof. Helmholtz, in Popular Science Monthly for June*.

LATE OBSERVATIONS ON JUPITER.—From seven years' observation of the surface of Jupiter, Herr Bredichin concludes that the inequalities in the angular velocity of the different figures seen on the planet may possibly be explained by assuming (1) that in the neighborhood of the equator there is a solid, elevated zone, which, however, does not rise beyond the limits of the atmosphere, and (2) that the crust of the southern hemisphere transmits more internal heat into the atmosphere than that of the northern, and this affects the direction of currents of gases and vapors passing from one hemisphere to the other. The phenomena observed in that part of the crust which appears through the vaporous layer as a red spot prove, he says, the considerably deeper position of this spot as compared with the equatorial zone, and the preponderating heat development on the southern part of Jupiter. Herr Bredichin gives the distances of the southern and northern borders of the elevated equatorial zone from the equator, for the years 1874 to 1880, and he finds that the equatorial zone must be steeper to the south, while it has a more gentle fall to the north, so that here it is varying, and covered more or less with clouds and vapors. The highest strip of this zone seems to be 2" from the equator, on the north.

BRAIN SUBSTANCE.—When brain substance is placed in alcohol, it loses its water and mobility of particles, and becomes more solid and firm. The question here arises: Is this thing possible with the living brain? Is it possible (asks the *Popular Science Monthly*), that, in cases of delirium tremens, so much alcohol has been consumed, that by its diffusion through the brain it has robbed nerve matter of its mobile character, and consequently of its power to throw off the products of its life functions? That alcohol may in this way act on the brain of the inebriate is an opinion which, as yet, can hardly be demonstrated directly, but experiments made, seem to render it highly probable. Brain substance, derived from an ox, was placed in a diluted solution of alcohol at the temperature of the blood, viz.: 100° F. When the liquid was drawn out after a few hours, and filtered, the filtrate threw down a white deposit of matter which the alcohol had dissolved out of the brain.

AN ACCIDENTAL DISCOVERY.—At a Berlin feather dyeing establishment an ostrich feather dyed in shades with methyl-violet was laid upon a paper upon which some ammonia had been poured but had dried up again. After a time the feather became partially green, the green passing gradually into violet, and producing an extraordinary effect. This reaction is being utilized in feather dyeing, and will probably be applied in the manufacture of artificial flowers.

An ingenious device for circumventing the practice of forgery has been invented. It consists of a chemically prepared cheese, printed in ink of two colors, of such constituents that if an alkaline solvent is used, one color will disappear; if an acid solvent is used, the other will disappear, and so mutilate the paper that detection will be inevitable.

THE ELECTRICITY OF ATOMS.—The most novel conclusion of Prof. Helmholtz, in his recent Faraday lecture, is to the effect that the atom of every chemical element is always united with a definite unvarying quantity of electricity. This quantity stands in close connection with the combining power of the atom which modern chemistry has termed valence. For if the amount of electricity belonging to the monad atom be taken as the unit, then that of the dyad is two, that of the triad three, and so on. "If," says Prof. Helmholtz, "we conclude from the facts that every unit of affinity of every atom is charged always with one equivalent, either of positive or negative electricity, they can form compounds, being electrically neutral, only if every unit charged positively unite under the influence of a mighty electric attraction with another unit charged negatively. You will see that this ought to produce compounds in which every unit of affinity of every atom is connected with one—and only with one—other unit of another atom. This is, indeed, the modern chemical theory of quivalence, comprising all the saturated compounds."

THE NOISE OF THE FINGER.—In a late number of the *Medical Record* Dr. Hammond says that when you poke the end of your finger in your ear, the roaring noise you hear is the sound of the circulation in your finger, which is a fact, as any one can demonstrate for himself by first putting his fingers in his ears and then stopping them up with other substance. Try it, and think what a wonder of a machine your body is, that even the points of your fingers are such busy workshops that they roar like a small Niagara. The roaring is probably more than the noise of the circulation of the blood. It is the voice of all the vital processes together—the tearing down and building up processes that are always going forward in every living body, from conception to death.

FOR THE MICROSCOPE.—M. Certe has lately found a method of coloring infusoria and anatomical elements during life. Placed in a weak solution of choline blue or cyanine, infusoria are colored pale blue, and many continue to live 25, and even 36 hours. Strong doses poison immediately. Again, after being 24 hours in a moist chamber, the white blood corpuscles of a frog colored with cyanine show amoeboid movements. The cyanine should here be dissolved in serum. Choline blue is, *par excellence*, the reagent of fatty matter. By affecting the cellular and not the nuclear protoplasm in infusoria, it shows fatty matters to exist only in the former. It should prove a useful means of studying cellular life.

FIRE-DAMP EXPLOSIONS.—Recent experiments of M. Michel Rossi tend to prove that explosions of fire-damp are preceded by light micro-seismic disturbances and faint subterranean noises, which the microphone detects with great sensibility. M. Rossi therefore suggests that local meteorological observatories should be established at collieries, and the microphone added to their ordinary equipment. The grating sounds by which this instrument indicates an escape of gas, together with the observations of temperature and pressure given by the thermometers and barometers would, he argues, go far to forewarn the superintendents of the mines, and thus prevent explosions.

THE CAMERA IN FORGERY.—It is stated that the bank of France has almost entirely abandoned chemical tests in favor of the camera for detecting forgeries. The sensitive plate not only proclaims forthwith the doing of the eraser or penknife, but frequently shows, under the bold figures of the forger, the sum originally borne by the check. So ready is the camera to detect ink marks that a *carte-de-visite* inclosed in a letter may to the eye appear without blemish, while a copy of it in the camera will probably exhibit traces of writing across the face, where it has merely been in contact with the written page.

THE death is reported of Mr. F. A. Nobert, the celebrated producer of test plates for microscopists. He had been engaged for many years in ruling micrometers and diffraction plates, and produced one set of lines—his nineteenth hand—equivalent to about 112,000 lines to the inch, which he believed could never be seen resolved in the microscope. Dr. Woodward eventually produced photographs of the finest of these lines; when Mr. Nobert ruled a new plate, the finest band of which—the twentieth—was of a fineness equivalent to about 224,000 lines to the inch.

A SCIENTIST in the *Magazine of Pharmacy*, asserts that the usual physico-chemical methods for determining the potable nature of water have proved themselves to be quite insufficient, and he says that "recourse must be had to the microscope and to the culture-glasses used by physiologists in their inoculation experiments before any really sound and valuable knowledge can be gained by the examination of waters" as to their purity or impurity.

NEW ARTIFICIAL MINERAL.—During fires in coal mines, various substances have been found to be formed. Among them, at Commentry, M. Desbreaux has discovered a new magnetic mineral which contains phosphorus and small quantities of arsenic and sulphur. This substance resembles various natural minerals and some meteoric stones. A similar substance is found in veins of silicate containing vivianite.

CONTRIBUTIONS TO THE GEOLOGY OF CALIFORNIA.—We begin this week a series of articles on this subject from the pen of Prof. W. P. Blake, a gentleman too well known to the mining community to need any introduction by us. The first paragraph of the contribution explains why the articles were written. We are very glad to be able to publish them, and can congratulate the miners of the coast on the fact that Prof. Blake has consented to write them. We shall have more to say on this subject in our next issue.

AWARDS TO INVENTORS.—The Board of Managers of the Sixteenth Industrial Exhibition have decided to award only Institute and Inventor's medals to exhibitors. The fair will open August 2d.

## MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertisements in Mining and Scientific Press and other S. F. Journals

ASSESSMENTS—STOCKS ON THE LISTS OF THE BOARDS.

						C Hildbrandt	11Cor Bush & Monty

Of the late run of the mill by Messrs. Pheby & Anthony be reports the following: Some 300 tons of ore were worked, about 100 tons of the Hemlock, 100 tons from Wyoming, and the balance from chert. On the 20th ult. the mill shipped 6 bars of bullion weighing 355 lbs., 850 fine, and on the 27th 4 bars weighing 323 lbs., 900 fine. Mr. Robinson came in after quicksilver, and having secured about a ton, will return with it in time to complete the present run.

**BEAVERDICK DISTRICT.**—It is stated that the new trail being built by Mr. Hunter and the mill and mine, 1000 from Juncos camp to Taylor, McKoy & Co.'s mill in Freestone canyon, will be completed next Monday. It comes a distance of 4 miles, and descends altogether from the mine to the mill about 4,000 ft., over one of the roughest regions outside of the moon. To get the auriferous quartz to the mill will require about 40 mules, to supply the requisite 9 tons to keep the little 5-stamp mill in operation day and night. The owners of the Key Note have contracted to supply at least 250 tons of ore for the first run.

**AT CARRO GORDO.**—Mr. Geo. Center, formerly superintending smelter at the Union Con. works, has lately been studying up the property with a view to leasing and starting up work. We understand that he is ready to go ahead provided the company will make certain connections from the 900 level to the new shaft to the old works, which it is to be hoped they will do.

## NEVADA.

**EAOLE MINE.**—*Nevada Transcript*, June 2: To-day the steam hoisting and pumping works just erected by W. H. Smith, the grocer, on the Eagle quartz mine, at Gallows Flat, adjoining the city limits on the east, will be regularly started up. The machinery has a capacity to sink 500 ft., and is the largest of its kind in the State. The incline, which is already down 74 ft. on the ledge, will be sunk 100 ft. more, at which point levels will be run. The ledge is about 6 inches thick in the bottom of the incline, and is increasing in size as it descends. This claim was discovered in 1855, and since then has been worked irregularly by various parties who have altogether taken out \$30,000 within 80 ft. from the surface, some of the explorations being made by tunnel. Within the last two years the results have been especially encouraging. 25 tons taken from the incline and vicinity, paying \$1,230. Eleven tons more taken out within 20 ft. of the bottom of the incline yielded \$604, while 11 tons from a back ledge in the same locality paid \$303. The mint certificates verify these figures. Mr. Smith, who recently purchased this property, has had his eye on it for a long time. Years ago, when engaged in hauling quartz for other mine owners, he saw an excellent opportunity to put himself as to its merits. He proposed to work it on the same principle that he conducted his store business.

**PEARL CON.**—*Nevada Transcript*, June 4: The Pearl Con. M. Co. of this city, whose claim is on the South Yuba 4 miles north of here and a short distance below Kirkham & Hitchcock's quartz mine, have after several months of prospecting in a quiet way made some developments that promise to be permanent and profitable. The east drift from the bottom of the main tunnel, which is in a distance of 131 ft. and is 300 ft. below the croppings of the ledge and 700 ft. below the brow of the mountain, has in the course of its progress opened on to some very fine sub-uptore. Fifteen ft. after leaving the tunnel it passes through the first vein of gold-bearing quartz. This deposit is of low grade, but would probably pay for working. Thirty ft. in another pay streak is encountered that assays in the neighborhood of \$200 ton in gold. At 45 ft. a splendid vein is encountered. Among the assays one ore at the rate of \$24 a ton in silver and \$5 a ton in gold. The drift is in quartz all the way, being on the foot wall. The ledge is clearly defined, about 7 ft. thick, and on the dividing line between granite and slate. The Pearl Con. is a local incorporation, the stockholders being well-known business men and miners who are paying for the work by voluntary contributions instead of by the usual assessment plan.

## PLACER.

**REDSTONE.**—*Placer Times*, May 23: The Redstone quartz mine is looking very promising just now. The prospect for something big becomes more encouraging as the work progresses. The owners have one of the new Huntington oscillating crushers in which the quartz is crushed. Last week a lot of seven tons of the ore from their claim was run through the mill and a clean-up made, from which it is reported that \$600 of gold was realized. This encourages them to go ahead. The location of the Redstone is in Little Bear valley, near Towle Bros.' upper sawmill, about 12 miles from Dutch Flat. In that vicinity we are informed extensive quartz ledges are traceable on the surface of the ground, but heretofore they were thought to be worthless and no notice was taken of them. The Redstone claim is owned by Messrs. John Leiber, Bart. Allen and Dave Driscoll, all of whom came from Oakland.

**RISING SUN.**—*Placer Herald*, June 4: At the Rising Sun mine, at Colfax, which runs nrauks among the solid mining enterprises of the country, a great deal of work is being carried on. Fourteen or fifteen months ago this mine was purchased by New York parties, and in about 12 months they have increased the production of the mine in excess, we understand, of the cost of the mine. Encouraged by this flattering result, they concluded to increase the capacity of their mill and make other improvements. The mill, which contained 10 stamps, has been increased to 20. The engine is being replaced by a new and larger one; self-feeders will be put in, another pair of Eucre rubbers will be added, and the concentrating machinery will be increased in proportion to the increased capacity of the mill. The pumping engine is also to be replaced by a larger engine. In order that there may be no doubt about keeping the 20 stamps employed, a new hoisting shaft is being sunk on the ledge some 800 ft. west of the present works. This shaft is now down a little more than 100 ft. At that depth the vein is from 2 1/2 to 3 ft. and the rock looks very well. A fine building and steam hoisting shaft will be put on this new shaft at once. The work of putting up these additions, making these changes and repairs, is being done under the direct supervision of Mr. J. K. Gwens, a millwright whose work speaks his ability. Supt. Wm. Werry, to whose experience and good management much of the success of the new company is due, hopes to complete these extensive changes and commence crushing again by the 15th of this month. In the mine this 900 level is under water in consequence of interruption to the pumping machinery, made necessary by the changes. In a drift on the 500 level some very rich ore has been struck east of what is supposed to be the regular pay chute. It seems to be something new, and is regarded by Supt. Werry as a very important development. When they start up again, with the improved appliances and increased machinery, Mr. Werry hopes to take out from \$10,000 to \$15,000 a month over and above expenses.

## PLUMAS.

**GENESSE HILL CLAIM.**—*Plumas National*, June 4: Wils. Dean writes us that he has run a prospect tunnel on the Genesee hill claim, and has got the bottom. He struck gravel the first day, and finds the channel 40 ft. wide, with gold all through the drift. This insures a good piling claim, and as soon as the pipe arrives he will make things lively. At present he is ground sluicing, and he regards his prospects as very encouraging.

## SHASTA.

**MAD OX MINE.**—*Shasta Courier*, June 4: The south lode or tunnel is in about 300 ft., drifting on the lode 200 ft. to the north, and 100 ft. to the south. The ledge in the tunnel is 8 ft. wide in the north end, and 14 ft. wide in the south, and is about 2 ft. wide in the raise. All of the ore in the raise and at both ends is good pay ore, yielding from \$18 to \$25 per ton. So far they have not taken any ore from the stope, which are very rich, but have been using all the ore they crush from the tunnel or main level. The Supt. calculates that this end of the mine will give them enough pay ore to run 6 years with a 5-stamp mill or 3 years with a 10-stamp mill. The mine is owned by J. Strode, O. P. Woodward and A. Grofeland. The extension to the Mad Ox mine is owned by Warfield, Solan,

Scott, McDonald & Co., and has paid its owners large dividends in the past. The company have been running new shafts after gold through the mine, and we returned to the mill. It is a 5-stamp mill, Laffell wheel, run by water-power, with 60 ft. of plate and a crushing capacity of 6 tons in 24 hours. The company talk of putting in 6 more stamps soon.

## SIERRA.

**HEAVY GOLD.**—*Mountain Messenger*, June 4: On Sunday last a piece of gold weighing 60 ounces was found in the dump of the Bald Mountain, at Forest city. This specimen is particularly fine looking, being something in the shape of a retort. The large end is almost round and as large as a small man's fist. Several pieces of 10, 12 and 15 ounces were taken out the same day. The large piece was discovered among the gravel before it was washed.

The Bald Mountain Extension Co. are putting up a large dump to hold their summer's gravel. One track is up and lumber is out for two more. From the bottom the last bent to the bottom of the sluices will be about 60 ft. The gravel in all the gangways looks better than it has yet appeared. Eleven men are working inside.

A late note—it will be about three weeks before the Alaska mill will be ready to begin crushing rock. The company is busy raising a shaft for air.

This Sierra Buttes quartz M. Co.'s dividend for April amounts to 25 cents a share, aggregating \$30,000; and that of the Plumas Eureka 75 cents, \$105,000. In this part of the State are many undeveloped quartz mines capable of being proved just as valuable and productive as those whose steady dividends of years have contributed not a little to the prosperity of the State.

**WATER.**—It will be several weeks yet before the Brush Creek mill will be free of water. The pumps are running steadily, and the water is slowly receding, but as they have got down to where there are some long drifts, it is necessarily slow work.

**BUILDING.**—The Bald Mountain Co. are busy putting up heavy timbers across their large dump, and otherwise preparing the summer's work. The timbers being used are extra heavy.

**PROF. BLAKE.**—Prof. Blake, the gentleman who reported on the Sierra Buttes quartz mine for the English company, which purchased it from the Reese Bros., was in town last week. He went over and examined the Extension Co.'s property, going up the ridge as far as American hill, taking in the University claims on the way. The Professor says the country goes up the ridge beyond a doubt, as he finds in the gravel formations that can be found nowhere in this section except above Sierra city.

## TUOLUMNE.

**MINE BONDED.**—*Union Democrat*, June 4: R. C. Davis, Joseph Cavanaugh, John D. Erickson and John Conley have agreed to sell the Continental and Sonnet mines by their extensions, to W. H. Buckley, of Ancona, Nevada, and Leonard Richardson, of New York, for \$75,000. Two thousand dollars was paid on signing the contract, the balance, 73,000, is payable within 90 days, or the amount paid will be forfeited. Another party offers to take the property and pay down for it. The mines are now being worked. The Continental is running 20 stamps, crushing 28 tons daily. Recent developments in the 3d, 3d and 4th levels show up a vein 10 ft. in thickness, all of which is good milling ore. The rock now being worked is from this vein, and pays regularly \$10 to \$12 per ton.

## NEVADA.

### WASHOE DISTRICT.

**UNION CON.**—*Enterprise*, June 5: On the 2500 level the joint Mexican winze has been sunk and timbered 12 ft., and the joint Sierra Nevada winze 15 ft.

**UNION SHAFT.**—During the week the shaft has been sunk and timbered 14 ft. The ground at the bottom is becoming somewhat softer. The west drift on the 400 level has been cleaned out and repaired a distance of 600 ft., and a drift started north from that point.

**NEW WELLS FARM.**—The work of boring the water from the shaft is progressing well. We are having a new tank constructed with a capacity of 270 gallons, which will be in use by Tuesday. We expect then to reach the 500 level in a few days.

**YELLOW JACKET.**—The water in the mine this morning is five ft. below the 2700 station. There is upwards of 35 inches of water coming into our mine on this level from the Imperial group of mines. We find all the drifts on the 2700 level in excellent condition. Not more than two car loads of ground has fallen from place throughout the level.

**SUBTUNNEL.**—Drain boxes covered since last report. 230 ft. total, 1700 ft. Single line of large drain boxes put in since last report, 320 ft.; total, 1,006 ft. Sills for large boxes put in since last report, 018 ft.; total, 1,125 ft. Sub-drain excavated since last report, 119 ft.; total, 1,219 ft. The sub-drain is now completed to the Combination connection, and 40 ft. beyond this point is being excavated for the purpose of putting in two boxes to allow us sufficient room for connection with the Combination and the Sierra Nevada south lateral drain boxes. The nature of the ground in the header is hard and timbering, and the character of the rock is andesite and vein porphyry. During the week we have covered 20 ft. of the south lateral drain boxes and placed in position 300 ft. of blower pipe. The drill carriage has been removed from the drift to the machine shop and is being cut down and repaired.

**CONSOLIDATED VIRGINIA.**—On the 2500 level the joint California east crosscut has been extended 27 ft., and the south drift hole 55 ft.

**UTAH.**—During the past week the incline has been sunk and timbered 14 ft. The ground at the bottom is becoming somewhat softer. The west drift on the 400 level has been cleaned out and repaired a distance of 600 ft., and a drift started north from that point.

**NEW WELLS FARM.**—The work of boring the water from the shaft is progressing well. We are having a new tank constructed with a capacity of 270 gallons, which will be in use by Tuesday. We expect then to reach the 500 level in a few days.

**YELLOW JACKET.**—The water in the mine this morning is five ft. below the 2700 station. There is upwards of 35 inches of water coming into our mine on this level from the Imperial group of mines. We find all the drifts on the 2700 level in excellent condition. Not more than two car loads of ground has fallen from place throughout the level.

**SUBTUNNEL.**—Drain boxes covered since last report. 230 ft. total, 1700 ft. Single line of large drain boxes put in since last report, 320 ft.; total, 1,006 ft. Sills for large boxes put in since last report, 018 ft.; total, 1,125 ft. Sub-drain excavated since last report, 119 ft.; total, 1,219 ft. The sub-drain is now completed to the Combination connection, and 40 ft. beyond this point is being excavated for the purpose of putting in two boxes to allow us sufficient room for connection with the Combination and the Sierra Nevada south lateral drain boxes. The nature of the ground in the header is hard and timbering, and the character of the rock is andesite and vein porphyry. During the week we have covered 20 ft. of the south lateral drain boxes and placed in position 300 ft. of blower pipe. The drill carriage has been removed from the drift to the machine shop and is being cut down and repaired.

**CONSOLIDATED VIRGINIA.**—On the 2500 level the joint California east crosscut has been extended 27 ft., and the south drift hole 55 ft.

**UTAH.**—During the past week the incline has been sunk and timbered 14 ft. The ground at the bottom is becoming somewhat softer. The west drift on the 400 level has been cleaned out and repaired a distance of 600 ft., and a drift started north from that point.

**YELLOW JACKET.**—The water in the mine this morning is five ft. below the 2700 station. There is upwards of 35 inches of water coming into our mine on this level from the Imperial group of mines. We find all the drifts on the 2700 level in excellent condition. Not more than two car loads of ground has fallen from place throughout the level.

**SUBTUNNEL.**—Drain boxes covered since last report. 230 ft. total, 1700 ft. Single line of large drain boxes put in since last report, 320 ft.; total, 1,006 ft. Sills for large boxes put in since last report, 018 ft.; total, 1,125 ft. Sub-drain excavated since last report, 119 ft.; total, 1,219 ft. The sub-drain is now completed to the Combination connection, and 40 ft. beyond this point is being excavated for the purpose of putting in two boxes to allow us sufficient room for connection with the Combination and the Sierra Nevada south lateral drain boxes. The nature of the ground in the header is hard and timbering, and the character of the rock is andesite and vein porphyry. During the week we have covered 20 ft. of the south lateral drain boxes and placed in position 300 ft. of blower pipe. The drill carriage has been removed from the drift to the machine shop and is being cut down and repaired.

**CONSOLIDATED VIRGINIA.**—On the 2500 level the joint California east crosscut has been extended 27 ft., and the south drift hole 55 ft.

**UTAH.**—During the past week the incline has been sunk and timbered 14 ft. The ground at the bottom is becoming somewhat softer. The west drift on the 400 level has been cleaned out and repaired a distance of 600 ft., and a drift started north from that point.

**NEW WELLS FARM.**—The work of boring the water from the shaft is progressing well. We are having a new tank constructed with a capacity of 270 gallons, which will be in use by Tuesday. We expect then to reach the 500 level in a few days.

**YELLOW JACKET.**—The water in the mine this morning is five ft. below the 2700 station. There is upwards of 35 inches of water coming into our mine on this level from the Imperial group of mines. **CONSOLIDATED VIRGINIA.**—On the 2500 level the joint California east crosscut has been extended 27 ft., and the south drift hole 55 ft.

This New York incorporation will not sell a share of the stock set aside to be sold to raise money with which to build a 10-stamp mill for less than \$1.50 per share; and will not sell any of their own at present at any price.

The Cortez, which belongs to another New York company, is increasing its force of miners every day as they can find room for them. They have their incline down now from the tunnel about 100 ft. in the ledge; have a double runway for their buckets, and everything running in good shape.

The Utah, owned by W. M. Seawell and Mr. G. W. Dorn, lies northeast of and adjoining the Cortez, on the same vein. After making surveys and a thorough examination of their tunnel and workings, they commenced work in their shaft, cleaning it out and having it timbered up in good shape. When this is completed they can commence at once to take out good ore.

The Centennial is looking and yielding about the same quality of ore as the Cortez report. They will commence crushing some in the little mill next week.

The New Emeralds.—Some Bodie mining men have been out to examine this property. They were very well pleased with the appearance of it, and took a good deal of the rock away with them to have it tested. A gentleman who visited this property lately says that the ledge, where crossed with the tunnel, is 70 ft. thick, although they are only claiming a width of 10 to 15 ft.

## I X L DISTRICT.

**BAFFIELD.**—*Cor. Silver State*, June 3: The Baffield Co. are down 200 ft., and are now drilling, having passed through a body of very hard line ore, assaying from \$30 to \$40 per ton. There are thousands of tons of this ore already in sight, the drift passing through a body of it for a distance of 40 ft. Not much else is being done on the east side, as parties seem to be waiting for further developments in the Baffield.

## PIKE HOLLOW DISTRICT.

**NEW DISTRICT.**—*Silver State*, June 3: I X L District is located on the divide of the Bull Creek range, while Pike Hollow has been organized as a new district on the west side. This district bids fair to be the better of the two. The Sweepstakes mine, owned by Messrs. Allen, Wightman & Co., is now down 50 ft. on a well-defined ledge from 2 to 6 ft. wide, of free milling ore, which assays from \$150 to \$600 per ton. It is the intention of this company to sink a 200 or 300-ft. shaft, run drifts and take out ore. Parties are at present from San Francisco looking out for a mill site, and say that a 5-stamp mill will be erected by Sept. 1st. The Gray Eagle and Little Wonder mines are located on the same ledge as the Sweepstakes, and are being prospecting with very flattering results.

## TUSCARORA DISTRICT.

**TUSCARORA M. & M. Co.**—*Times-Review*, June 2: Commenced drifting from the 100 level. Ledge from 1 to 2 ft. wide, carrying some good ore.

**INDREPENDENCE.**—Crosscut on 600 level extended 24 ft.; now in 103 ft.

**TUSCARORA TUNNEL.**—During the past week the tunnel has been extended 22 ft.; total, 23 ft. Ground works well.

**NORTH BELLE ISLE.**—The north upraise from the 150 level exposes fine ore in limited quantities. All other work in the mine is confined to stoping above the 150 level. The ledge is from a seam to 2 ft. thick. Ore high grade.

**BELLE ISLE.**—The north intermediate drift above the 250 level has been extended 10 ft.; total, 34 ft. The vein in this drift will average about 5 inches in width of good ore.

**ARONETA.**—Have started a raise from the 000 level, 112 ft. east of winze. The ledge is 18 inches wide, showing good ore.

**GRAND PRIZE.**—During the past week have been making some needed repairs in the shaft.

**NAVAGO.**

## An Injunction Against Hydraulic Mining.

The debris question has now assumed a shape which points to a more speedy solution than was anticipated. An action has been commenced by the People of the State of California, by A. L. Hart, its Attorney-General, against the Miocene M. Co., in the Superior Court of Sacramento county, where the complaint was filed. It is asked by the plaintiff that said mining company be enjoined and restrained perpetually from discharging or dumping into the Feather river, or causing or suffering to flow into said river any tailings from its lands or mine. The people will be represented in the action by Attorney-General A. L. Hart, J. H. Craddock and George Cadwalader and P. Van Clief, of counsel.

The Sacramento *Beaver* says the complaint is quite lengthy, covering 17 pages of printed matter. It commences by setting forth that the Sacramento and Feather rivers lie entirely within the limits of the State of California; that they are navigable streams and have been so declared to be by the Legislature; also, that the navigation of the Feather river has been seriously impaired by the deposit therein of tailings from the hydraulic mines. A description is then given of the manner in which hydraulic mining is conducted in the counties of Butte, Yuba, Sierra and Nevada, and it is represented that the tailings from all the hydraulic mines worked in those four counties are discharged into the Feather river and the streams tributary thereto; also, that a large portion thereof has been deposited and lodged in the bed and channel of the Feather river throughout its entire length below the town of Oroville, in Butte county, but a large portion thereof has been washed and carried by the water into and down the Sacramento river and deposited in the bed and channels of the last-named river throughout its entire length below its junction with said Feather river.

It is further set forth that prior to the month of February, 1881, and before the commission of the wrongful acts by the defendant herein-after complained of, the

### Deposit of Tailings

From the hydraulic mines, as aforesaid, in the beds and channels of said rivers had filled up and raised said beds and channels to a considerable extent in the lower portions of said rivers and to a much greater extent in the upper portion of the navigable part of said Feather river, and had greatly widened the beds of said rivers and shallowed the channels thereof, and thereby had considerably impaired and obstructed the navigation thereof, and had caused said rivers to overflow their banks and to submerge large portions of the adjacent lands—the property of citizens of this State—during the seasons of high water, and thereby interfered with and obstructed the free and comfortable use and enjoyment of said lands by the owners and occupants thereof, to a much greater extent than at any time before said rivers were so filled up, as aforesaid, by said tailings, and to a much greater extent than said lands would have been overflowed, or the use and enjoyment thereof would have been interfered with or obstructed had not said tailings been so deposited as aforesaid, in the beds and channels of said rivers.

### What the Defendant Has Done.

The complaint then goes on to recite that the defendant herein, the Miocene M. Co., is a corporation organized in the State of New York, under and by virtue of the laws of the State of New York, for the purpose of mining in Butte county of the State of California.

That prior to the month of February, 1881, said defendant acquired the possession of, and claims to own a large tract of mineral land, to-wit: About 1,500 acres, situate adjacent to said Feather river, on the north side thereof, about one mile above the said town of Oroville. The surface of said tract of land is generally about 200 ft. above the low-water level of said Feather river, and is susceptible of being worked and mined by said hydraulic process to a depth of about 30 ft. below the surface, and to that depth is composed of various strata of cement, gravel, pipe-clay and sand, the greater part of which, except the pipe-clay, containing small particles of gold.

That by means of a ditch and iron pipes, defendant has conducted to said mine a constant supply of 3,000 inches of water, which it is using, and will continue to use, under a vertical pressure of 350 ft., to mine its said tract of land by said hydraulic process, discharging the water through monitors, from nozzles of eight inches in diameter, and dumping all the tailings from such mining directly into said Feather river, immediately adjacent to said tract of mineral land.

That the defendant commenced to mine in said tract of land in the mode and by the process aforesaid, on or about the — day of February, 1881, and since that time has discharged and

### Dumped Into Said Feather River,

At a point adjacent to said tract of land, 12,000 cubic yards per day of solid material from said mine, composed of small boulders, cobble stones, gravel, sand and clay, during all the time it has so mined, and at that rate it will require over 20 years to mine out and exhaust said tract of land. And plaintiff further shows that the defendant, by its agents, has declared its intention, and really intends, to continue to mine said tract of land in the manner and at the rate aforesaid, and to discharge and dump the tailings from such mining ground into Feather river

as aforesaid, until said tract of land shall be mined out and exhausted, and will so continue to mine, and to discharge and dump said tailings into Feather river, unless enjoined and restrained by order of this honorable court. That the tailings discharged and dumped into Feather river by the defendant as aforesaid, have been washed and removed down said rivers by the natural force of the waters, and commingled with tailings from other hydraulic mines, and with them have been deposited and lodged in the beds and channels of said rivers and upon the lands adjacent to said rivers.

That since the defendant commenced to mine its said tract of land as aforesaid, the beds and channels of the Feather and Sacramento

### Rivers Have Been Filled Up.

Raised, widened and shallowed by the deposits therein of tailings from the defendant's mine, and other hydraulic mines as aforesaid, to a much greater extent than at any time before, and, by reason thereof, the navigation of said rivers has been impaired and obstructed, and the banks thereof and the lands adjacent thereto have been overflowed and injured to a much greater extent than at any time before the commencement of such mining by the defendant as aforesaid, and that by said mining and discharge of tailings into Feather river by the defendant as aforesaid, said defendant has largely and materially added and contributed to the said filling up, raising, widening and shallowing of the beds and channels of said rivers, and to the impairment and obstruction of the navigation of said rivers, and also to the said excessive overflow of the banks and lands adjacent to said rivers, to the great injury of said lands, and to the damage, discomfort and intolerable annoyance of the owners of said lands, and the residents thereon.

After alluding to the fact that the greater the depth of the water flowing the greater is its

### Force and Power to Scour Out

And carry off the deposits in a river, the complaint goes on to recite that the river beds have already become so much filled up and widened by the tailings from the hydraulic mines, including those of the defendant, that the depth of the water therein has been thereby greatly diminished, especially during the high stages of the water, when the water overflows the banks of said rivers and spreads over large tracts of land on each side of said rivers, instead of being confined within the natural banks, as it would have been but for said deposits therein from the hydraulic mines. That by reason of the diminution of the depth of the water in the beds and channels of said rivers, they will hereafter be filled up and the navigation thereof obstructed much more rapidly in proportion to the quantity of hydraulic tailings deposited therein than formerly, when their waters had greater depth and greater purity, and consequently more power to scour out and carry off such deposits. That a continuance of the deposits of tailings from the hydraulic mines, including that of defendant, during the next two years, at one half the rate they have been deposited for the last two years, will totally destroy the navigability of said Feather river, and further obstruct and impair that of the Sacramento river, and will submerge and

### Render Unfit for Cultivation

Or habitation all the bottom and other lowlands adjacent to said rivers, on both sides thereof, by the overflow thereof and the deposits thereon of sand and gravel from said hydraulic mines to such depth as to render said lands unproductive and valueless. That more than 50,000 acres of such lands of first-rate quality, and of great value, have already been so overflowed and covered by a deposit of sand and tailings from said hydraulic mines, to which the tailings from said mine of the defendant has largely and materially contributed, to a depth of from 1 ft. to 15 ft., and have thereby been rendered totally unfit for cultivation or any other useful purpose, and of no value whatever. That there are in the valley of said Feather river, below Oroville and within reach of its overflowing waters, over 100,000 acres of valuable agricultural lands—the property of citizens of this State—highly improved and cultivated, which remain uninjured, or injured only in a small degree by the overflow thereof and deposits thereon, of tailings from said hydraulic mines, but which will be subject to such overflow and deposits thereon, and which will be overflowed by water and covered by a deposit of tailings from said hydraulic mines, including that of the defendant, and thereby greatly deteriorated in value and usefulness to the owners thereof, if not rendered totally useless and of no value whatever, within a very short period of time, if hydraulic mining be continued by the defendant and others, as at present conducted; and plaintiff is informed and believes, and upon such information and belief alleges, that unless restrained and enjoined by this Honorable Court, such hydraulic mining will be so continued by defendant and others during the next 20 years, to the utter and total destruction of all the agricultural lands and the improvements thereon, and of all the cities and towns within the valley of Feather river, and within the valley of the Sacramento river below the town of Princeton, in Colusa county.

### Fouling the Waters.

Plaintiff further shows that the discharge and deposit of tailings by defendant from its mine so fouls and adulterates the waters of the Feather river at all points below defendant's mine, and down to the junction of the Yuba river, as to render the waters unfit for any use by the in-

habitants of said valley, and that in the absence of such fouling and adulterations, the waters were and still would be of first rate quality for all purposes for which water is used by man and beast.

It is then set forth that the filling up of the beds of the Feather and Sacramento rivers by tailings from the hydraulic mines of defendant and others has resulted in the great obstruction of the natural and artificial drainage of the lands, and the sewerage of the cities and towns in the Feather river and Sacramento valleys, and thereby said valleys have been rendered more unhealthy to the inhabitants thereof than they otherwise would have been, and will thereby continue to be rendered still more unhealthy by the continuance of hydraulic mining as conducted by defendant and others.

It is further set out that if hydraulic mining by defendant and others is stopped and not again resumed, that the waters of said rivers will at once commence to scour and carry off the tailings heretofore deposited therein, and within a few years will thereby restore said rivers to their former and normal conditions of navigability, deep channels and pure water.

### Why the Action was Brought Here.

Plaintiff further states that the wrongful acts of the defendant constitute a public nuisance of a continuously recurring nature, produced and continued by repeated wrongful acts of defendant, and not subject to abatement, but that the only appropriate or adequate remedy for which is by injunction from a court of equity, and for which there is no remedy at law except by information or indictment, as for a misdemeanor, the penalty of which is, and will be, totally inadequate to suppress the wrong; besides, such misdemeanor must be prosecuted in the county where it is committed, and is there triable by a jury, where it would be difficult, and generally impossible to convict the offender, by reason of the great influence of those generally guilty of the offense, and from a fact that a majority of the people in those counties where the offense is committed regard the wrongful acts herein above complained of as constituting no public offense. That the prospect of real and speculative profits from hydraulic mining, as herein above described and complained of, is generally such that persons engaged in it would suffer all the prosecutions and penalties of the law that could be inflicted upon them, rather than discontinue the commission of the offense; besides numerous and repeated prosecutions of each offender would be necessary to produce any effect whatever.

It is further set out that the navigability of said Sacramento and Feather rivers, and the value and usefulness of the agricultural lands of said valleys, and the roads and highways therein, are in imminent danger of total and irretrievable destruction by the wrongful acts of defendant, above complained of, and that such destruction can only be prevented by the writ of injunction from a court of equity.

Also, that if the wrongful acts of defendant and others, above complained of, are continued, the beds and channels of the upper portions of said rivers will very soon be filled and choked up by tailings from defendant's and other hydraulic mines; that said rivers will be turned from their natural beds and channels and spread and run at random over the entire valleys, in which condition the depth of their waters will be so diminished that they will have no force or power to scour said channels or to carry off the tailings deposited therein as aforesaid, and said valleys will become dismal swamps.

### What is Asked For.

In conclusion, the plaintiff prays that during the pendency of this action the defendant and all its officers, agents and employees may be restrained from discharging or dumping into said Feather river, or causing or suffering to flow into said river any tailings, boulders, cobble stones, gravel, sand, clay, debris or refuse matter from its said tract of mineral land, mine or elsewhere; and that upon the final hearing and trial of this action the said defendant may be so enjoined and restrained perpetually, and that plaintiff recover the costs of suit herein.

The complaint is subscribed and sworn to by S. E. Wilson, who has resided for the last 12 years on the northwest bank of the Feather river, nearly midway between Yuba City and its mouth, in Sutter county.

### The Injunction Issued.

In accordance with the petition of the plaintiff in the case, the injunction was issued by Judge Denson and served at once upon the mining company. As a result of this a number of miners have been discharged from some of the leading hydraulic mines, as will be seen by an article in another column of this number.

COMPOUND steel shafting is now made in Boston. An ordinary round steel shaft is made to pass through a peculiarly devised circular die, which compresses but does not elongate the shaft, and by which a 2½-inch steel shaft is reduced in diameter fully 1-16 of an inch. This compression materially increases the strength of the shaft, so far as its corrosion is concerned, (and that is the most vital point in shafting), something like 2½ times over that of the best wrought iron shafting; moreover the face of the shafting is left much better finished than is possible with any turning, filing or polishing tools.

THE *Homer Mining Index* says: A pack mule with 600 pounds on his back is not a strange sight in Lundy, but a millionaire with a dollar in his pocket would be a novelty.

## No Double Taxation in California.

An opinion by Justice Ross, concurred in by all the Justices of the Supreme Court, has been filed in the case of John H. Burke, against Assessor Badlem, denying plaintiff's application for a writ of mandate. The opinion says: In this case we are asked by the petitioner to grant a writ of mandate, compelling the assessor of the City and County of San Francisco to assess upon the assessment roll thereof, to various corporations, the respective shares held by them, and to assess to various depositors in various savings banks the respective sums of money deposited by them. Whether the Assessor has or has not assessed to the respective corporations all of their property of every character, and to the respective savings banks all of theirs, including all moneys deposited with them, does not appear from the petition; but as the Legislature has required the assessor to do these things, we must presume that he has or will perform his duty in this respect in due time. The claim of the petitioner, however, we understand to be this: That the assessor must assess to all the respective corporations all of their property of every kind, including their franchise, and to the individual stockholders thereof the respective shares of stock held by them, and must assess to the respective savings banks all of their property, including all moneys deposited with them by depositors, and also to the individual depositors the respective sums of money so deposited by them. If this would in effect be assessing the same property twice for the same tax, it cannot be done. The Constitution of the State does not require or authorize double taxation. On the contrary, its language clearly forbids it. After citing authorities, the opinion says: What is the stock of a corporation but its property, consisting of its franchise and such other property as the corporation may own? Of what else does its stock consist? If all this be taken away, what remains? Absolutely nothing. When, therefore, all the property of the corporation is assessed, then all the stock of the corporation is assessed, and the mandate of the Constitution is complied with. This property is held by the corporation in trust for the stockholders. The share of each stockholder is undoubtedly property, but it is an interest in the very property held by the corporation. Property rights are confined to the property held by a firm, just as the property rights of the stockholder in a corporation are confined to the property held by the corporation. Take away all the property of a corporation, which includes its franchise, and the shareholder no longer has any property. If it is competent to assess to the corporation all the property held by it, and to the individual stockholders the respective interests owned by each therein, so must it be competent to assess to every partnership the property held by the firm and to each individual partner his interest therein. It is clear to our minds that in one case the partner, and in the other the stockholder, would be compelled to pay twice on the same property, which is neither required nor permitted by the Constitution. Justices McKinstry, Chief Justice Morrison and Justice Myrick specially concur in the opinion.

Chief Justice Morrison says: I concur in the views of Mr. Justice Ross so far as they relate to savings banks and deposits therein. I am of the opinion that money deposited in savings banks should be assessed but once, either to the bank or to the depositor, and not to both. On the other question involved in the case (the taxation of shares of capital stock of corporations), I express no opinion.

Justice Myrick says: I concur in the views expressed by Mr. Justice Ross, except as to the assessment to depositors of moneys deposited in the savings banks named in the petition. Upon that subject I express no opinion.

"SLUMGULLION."—"Slickens" is a granger word used in California to designate the slimy deposit or sediment which settles upon the farming lands irrigated with the dirty water from hydraulic and other mining operations in the mountains. The original and only proper and appropriate term for that stuff is "slumgullion." That was always its legitimate name from the earliest times down, among the old miners. Here in Nevada what is known as "slums" or "slimes" is the sediment from quartz milling operation, and carries a considerable amount of silver in form of chloride. Caught and settled in dams or ponds, some of these slums or slimes pay well for re-working. It is of a similar nature and consistency as the California slumgullion. "Slickens" What grass-haired cow boy gave it that name there in California? Anybody who ever waded through, shoveled or had anything to do with a deposit of that familiar old material knows that the only natural word which fully expresses its character is "slumgullion." The substitution of the word "slickens" simply shows degeneracy, and the degree to which California has become grangerized.—*Gold Hill News*.

NORTH of Laramie peak many discoveries of the precious metal have been made during the past year, and the recent find of a very rich deposit of silver and copper at Copperopolis, north of the North Platte, has given a new impetus to prospecting on that side of the peak.

REPORTS from Halifax (N. S.), say that gold has been discovered at East Chezzetcook, Halifax county. The specimens of quartz brought in are rich.

## THE ENGINEER.

**THE SECOND BRIDGE BETWEEN NEW YORK AND BROOKLYN.**—The bridge from New York to Brooklyn, crossing Blackwell's island, is under contract, and the contractors are now busy on the iron work of this pier foundations. The estimated cost of the bridge is \$5,000,000; the time fixed for its completion is three years. There will be four piers, one at Ravenwood, another at the coal dock on Blackwell's island, a third on the west side of the island, and the fourth on the New York side, between 76th and 77th Sts. The bridge will be 74 ft. wide, and will be arranged for two sidewalks, two carriage ways and two steam railroad tracks. The span over the water from Ravenwood to Blackwell's island will be 618 ft., that across the island 700 ft., and that over the river to New York 734 ft. Each pier will rest on bedrock, the dip of whose strata at all points is nearly vertical. The Ravenwood pier, only, will stand in the water. One corner, only, of the New York pier will touch the water. The roadway will be 154 ft. above the river at high tide.

**ELECTRIC RAILWAYS** appear to be a practical success. The electric railway on which Siemens and Halske, the Berlin electricians, have been for some time experimenting in that city, was publicly opened May 13th, in the presence of the railroad officials and a large number of scientific men. The road runs between the suburbs of Lichtenfeld and Cadettenhausen, a distance of six miles. A tram car was fitted up with an electric battery concealed between the wheels, the rails of the track being used as the conducting medium in connection with the principal battery at the station. The trial is reported to have been an entire success, a speed of 13 miles, the highest speed allowed by the authorities, having been obtained. The road is now in regular operation. Meantime, what has become of Edison's electric railway devices which he was long ago to set in operation? While the American inventor has been promising very largely, his European competitors seem to have been fulfilling.

**FLOODING THE SAHARA.**—Dr. Lenz, recently returned from an expedition across the desert to Timbuctoo, condemns as impracticable the project of flooding the Sahara. In his lecture, which was delivered before the Paris Geological Society, he says that fresh-water fossils are met with in many parts; therefore the desert is not the bottom of a salt sea. The temperature is not as high as might be expected; wild beasts are uncommon. The most formidable enemies are the Touareg tribes, who have, it is reported, lately massacred the French Trans-Saharan expedition. Per contra to the above, Commandant Roudaire has finished the investigations, which were indicated by the commission of the French Academy, in relation to the filling of the Tunisian and Algerian chotts by the sea. His conclusions are entirely favorable to the project, and would lead to the establishment of an interior sea 400 kilometers (248.55 miles) long and 1,600 kilometers (994.2 miles) in circumference.

**A PRIZE OFFER.**—The French Society for the Encouragement of National Industry, offers a prize of 2,000 francs, to be given in 1882, for an engine of 25 to 100 horse-power, to burn not more than 700 grammes, 1.54 pounds of good coal per hour per horse-power, and a prize of 1,000 francs for a motor, suitable for small workshops, of the power of from six to 20 kilogramme-metres per second. Similar prizes for a small motor were offered last year, the first being taken by a hydraulic engine, and the second by a gas motor, and it has been decided to offer the same again, in order to secure varied designs. Other premiums are offered for machines for various manufacturing processes; and in 1885, 3,000 francs will be given for the best method of conveying power to a distance.

**AN EXPERIMENT** made in the port of Kiel proves that heavy weights may be readily lifted from the bottom of the sea by means of a balloon. The balloon is made of canvas and metal plates, with an attached cistern containing carbonic acid gas compressed to a liquid state. When made fast to a sunken object, the communication between the cistern and balloon is opened; inflation takes place; the sunken vessel, or whatever else it may be, is lifted, and can be towed away at pleasure. In the experiment at Kiel, an anchor-stone weighing 15 tons, was thus lifted from a depth of 32 ft. The lifting power of a balloon 10 ft. in diameter is said to be more than 100 tons.

**THE PANAMA CANAL.**—Mr. John M. Wilson, United States Consul at Panama, who is now in Washington, says it does not look as though M. de Lesseps ever intends to build a canal there. Nothing has been done thus far. The little party of Frenchmen who are surveying and about 100 negroes constitute the whole native force.

**THE LONGEST SPAN OF WIRE.**—The longest span of telegraph wire in the world is stretched across the Kienah river from bill to bill, each bill being 1,200 ft. high, between Bezorah and Sectanagrum, in India. The span is a little over 6,000 ft. in length. The only mechanical contrivance used in stretching this cable across the river was a common windlass.

## USEFUL INFORMATION.

**GLASS-COATED TIN PLATES FOR CANNING.**—The liability of evil effects from the chemical action of acids and salts, in the substances packed in tin cans, has for a long time been a serious drawback to the canning and packing industry in this country as well as in England, and much study has been devoted to the subject of an improved material. A firm at Dunstable, England, it is said, has invented a method of coating tin-plates with a material which interposes a film resembling glass between the surface of the metal and the fruit or other contents. The insoluble portion of the composition is silicate of lime or fluo-silicate of lime (glass powder), previously acted on by fluoric acid; the soluble portion being silicate of soda and potash. Preferably, that kind of silicate of lime is used which has been produced by double decomposition from polysulphide of calcium, chloride of calcium and hydrate of lime; or, there may be used a silicate of the earthy bases or metals, or precipitated gelatinous silica. The alkali may be fixed or removed by a bath containing a dilute solution of fluo-silicic acid, when fluoric acid has not been used, or a dilute solution of any other suitable acid. To make the composition, mix the soluble with the insoluble silicate in equal proportions, although those may be varied according to the consistency required. The plates are coated with the composition with a brush, or by dipping into a bath. After coating, the plates are dried by heat and are ready for manufacture. This invention furnishes a plate with a surface somewhat resembling glass without the aid of infusion; and this coating, which is perfectly insoluble and unaffected by acids or salts, cannot be separated from the metal, which may be bent or worked in any manner desired, and cans thus made possess all the virtues of both glass and tin.

**A FILLER FOR POROUS HARD WOODS.**—Use boiled oil and corn starch stirred into a very thick paste. Add a little japan and reduce with turpentine. Add no color for light ash. For dark ash and chestnut, use a little raw sienna; for walnut, burnt umber and a slight amount of Venetian red; for bay wood, burnt sienna. In no case use more color than is required to overcome the white appearance of the starch unless you wish to stain the wood. This filler is worked with brush and rags in the usual manner. Let it dry 48 hours, or until it is in condition to rub down with No. 0 sandpaper, without much gumming up, and if an extra fine finish is desired fill again with the same materials, using less oil, but more of japan and turpentine. The second coat will not shrink, it being supported by the first coat. When the second coat is hard, the wood is ready for finishing up in any desired style or to any degree of nicety by following up the usual methods. This formula is not intended for rosewood, and will not be satisfactory if used therefor.—*T. F. Page, in the Coach Painter.*

**CONCRETE SLAG.**—The London (Eng.) Engineer says that the Aireside, Hematite Iron Co., which has introduced concrete slag as a substitute for building stone, has erected new offices at its works in Hunslet, Leeds, in which all the door and window facings and the ornamental work, are composed of the slag from its own furnaces. A new feature of such an elevation is a display of imitation carved bricks, in various colors, made of the slag, the cost of which is said to be 50% less than the real article of clay, which hitherto has been so much in fashion. The company also supplies the Midland and Northeastern railroad companies with slag concrete flags, ready for use in the laying down of platforms at railroad stations. The Staveley company has long used slag lumps for building.

**THE fusibility of soft solders** is increased by adding bismuth to the composition. An alloy of lead, four parts, tin, four parts, and bismuth, one part, is easily melted; but this alloy may itself be soldered with an alloy of lead, two parts, bismuth, two parts, and tin, one part. By adding mercury a still more fusible solder can be made. Equal parts of lead, bismuth, and mercury, with two parts of tin, will make a composition which melts at 122 F.; or an alloy of tin, five parts, lead, three parts, and bismuth, three parts, will melt in boiling water. In mixing these solders, melt the least fusible metal first in an iron ladle, then add the others in accordance with their fusibility. To cast strips of solder, pour the molten metal on a flat surface of stone or metal.

**HOW SLEIGH BELLS ARE MADE.**—It has no doubt been a mystery to many how the iron hall inside of sleigh bells got there, and it is said to have taken considerable thought on the part of the discoverer before the idea struck him. In making sleigh bells the iron hall is put inside a sand core, just the shape of the inside of the bell. Then a mold is made just the shape of the outside of the bell. The sand core with the jinglet inside, is placed in the mold of the outside, and the melted metal is poured in, which fills up the space between the core and mold. The hot metal burns the core so that it can be all shaken out, leaving the hall within the shell. Ball valve, ewell joints and many other articles are cast in the same manner.

**THE "CRY OF TIN."**—If a piece of tin be bent, it emits a sound; this, being regarded as a property peculiar to tin, has been termed the "cry of tin." This phenomenon is explained by the peculiar crystalline structure of the metal. Reasoning that, if this explanation be the true one, then other metals obviously crystalline in structure should also exhibit the same phenomenon, Mr. J. C. Douglas, who records his observations in the *Chemical News*, heated a piece of rolled zinc for a few minutes to a temperature somewhat below its melting point, when the metal became much less tough and its fracture decidedly crystalline. On bending a piece so treated, it emitted a sound weaker than that emitted by tin, but of the same nature. Cast zinc cannot be bent readily; but if pinched between the teeth or with pliers, it emits the sound distinctly. The conclusion, therefore, is that the cry of tin is due to crystalline structure, and may be emitted by zinc and probably by other metals when crystalline in structure. The practical application is, that by the sound a metal emits "we may draw conclusions as to its texture, and hence its fitness for certain purposes, or, by the sound emitted by a beam when bent, we may draw conclusions as to its safety, the microphone or other appliance being called in to aid us where the sounds are exceedingly weak."

**COOKING BY ELECTRICITY.**—Of the many curious things certain to be seen at the forthcoming exhibition of electricity at Paris, not the least remarkable will be the electrical cooking range of M. Salignac. That ingenious gentleman is going to fit up his apparatus in the grill-room of the restaurant, and intends to furnish a great variety of meats which have been cooked by heat generated from the electric current. At the last Paris Exhibition, M. Mouchot roasted mutton in condensed sunshine, and literally turned his spit on the hearth of the sun; but an enthusiastic admirer might say that M. Salignac had far surpassed this in broiling steaks by lightning and warming coffee with the aurora borealis. As a matter of fact, the electric current is as well fitted to produce heat as it is to produce light, and just as electricity will, in all probability be made to yield the principal artificial light of the future, so will doubtless it be applied to household heating. The same machines which light the house by night will heat and cook by day, besides performing other duties, such as driving a coffee mill or sewing machine.

**BIRCH FOR CABINET WORK.**—The small value of birch wood for fuel, and its lack of toughness and strength, except in the smaller twigs, have led to its general neglect in the arts. Our more enterprising builders of railway cars, however, have discovered that its light weight, close grain, and rich finish make it admirably suited for certain applications where fine finish and bright effects are desired. The contrasts presented when white birch and light colored ash are relieved by the red of the cherry birch, are said to be peculiar but very pleasing.

**NEW LUBRICANTS.**—K. Drechsler mixes graphite thoroughly with the whites or yolks of eggs, dries the mixture, pulverizes it and scatters it upon the parts of machinery which move slowly. G. Lieckfeld mixes graphite with soluble glass, so as to make a stiff broth. The mass is spread upon worn surfaces, where it soon hardens and can be filed or turned, so as to restore the machinery to its original perfection.

**VARNISH FOR METAL.**—A brilliant black is produced on iron and steel by applying, with a fine hair brush, a mixture of turpentine and sulphur boiled together. When the turpentine evaporates there remains on the metal a thin layer of clear sulphur, which unites closely with the iron when heated for a time over a spirit or gas flame. This varnish protects the metal perfectly, and is quite durable.

## GOOD HEALTH.

## How to Dress the Children.

There is no animal I know of born into the world in a greater state of helplessness than the human infant, and none more dependent upon artificial means to keep up the animal heat. It would very soon succumb to the cold if not protected. This is proved by the fact that a very much larger proportion of children die during the winter than during the summer months, although as regards the mortality of the young and middle aged, there is very little difference between those seasons. The older a child gets the better it becomes able to resist cold, but—and I would that mothers would bear this well in mind—until a boy or girl is well into his or her teens should foster warmth he looked upon otherwise than as a friend, or cold otherwise than as a deadly foe. Children in the cradle are seldom or never neglected by well-to-do parents, but it is when a child begins to run about, and is able to go out of doors, that mistakes are made about the clothing, which often leads to speedily fatal illness, or sow the seeds of future ailments, which render life a misery and a burden, that can be only laid down at the portals of the tomb. Instead of studying warmth and comfort in the clothing of their children, many mothers study only fashion. I speak advisedly, for I have proof of what I aver every day of my life.

It is not my province to tell my lady readers how to cut the patterns for their children's dresses, or even to choose the material from which to make them; but as a medical man it is my duty to remind them that the child who is clothed warmly, cleanly and neatly is far better dressed than one whose attire shows it to be a victim to a votaries of fashion. The one has a chance of turning out a healthy man and a useful member of society, the other has not. To those who are between the ages of 10 and 20 I have to say that, with no desire to advise them to be overclothed, and thus made hothouse plants of, too much attention cannot be paid to keeping them warmly clad. Cold is fatal to the young; warmth is life itself; cold retards the building up of the tissues of bone and muscle, warmth encourages it; cold interferes with the due performance of the functions of the skin, throws extra work on the liver and kidneys, and blunts the nervous energy of the brain itself; warmth has altogether a contrary effect.

Some parents labor under the erroneous impression that they are making their children hardy by allowing them to expose themselves to the deleterious effects of the absence of warmth. To maintain the normal heat in the young it is not necessary that the clothing should be heaped upon them, nor that they be carefully made prisoners of indoors, whenever the day is chill or the winds blow high. The clothing should be light rather than heavy—light and protective; and the material itself should be studied, not the quantity.—*Harper's.*

**ORIGIN OF DIPHTHERIA.**—The observations of Mr. G. H. Fosbrooke, medical health officer of Birmingham, England, have led him to form conclusions respecting the origin of diphtheria, which differ in some points from those which have been urged by other authorities. He regards it as a well-established fact, confirmed by his experience, that the disease is more common in rural than in urban districts, and has observed that even when it has prevailed extensively in a rural district, and has thence been conveyed into a neighboring town, it has not spread in the town. In one town of 5,000 inhabitants, diphtheria, when it occurred, prevailed concurrently with typhoid fever or scarlatina, giving rise to the suggestion that all those diseases might originate in a common poison. Mr. Fosbrooke does not agree with other authorities as to the conditions of soil most favorable to the propagation of diphtheria. Generally the disease has been thought to flourish most in damp situations and in connection with damp soils. All of his attempts to associate its origin and distribution with any peculiar soil or situation have failed, for he has met it both in villages occupying elevated and airy situations and in low places. The most serious epidemics, and the larger number of cases of which he has had personal knowledge, have appeared on soils that were "rather gravelly and well drained." With one exception, his experience opposes the idea that houses shut in by trees are more liable to harbor the disease than those which are not surrounded by an abundant vegetation. The fluctuations of diphtheria, when it prevails for any considerable length of time, do not appear to be influenced by changes of season or by variations of weather. Meteorological observations, made with reference to this point, differ widely, and furnish no guide to an opinion. The disease is generally found first to break out in October, and to prevail as an epidemic, when it does so prevail, in the winter months, increasing, as is natural with epidemics, during the earlier months of its course, but without regard to the regularity or irregularity of the season.—*Popular Science Monthly.*

**COD LIVER OIL.**—Under the heading of "Practical Notes," Mr. R. B. Fairthorne suggests, in the *American Journal of Pharmacy*, a new method of taking cod liver oil. As the use of this remedy is at the present time more extensive than ever before, any means employed whereby it can be more readily taken without causing disgust will prove of service to sufferers who have to use it daily. Mr. Fairthorne's method consists in adding two drams of tomato or walnut catsup to each ounce of the oil, the mixture being well shaken whenever required for use. He has found this mixture to agree with many persons much better than any other form in which cod liver oil has been taken, and this he attributes to the association of substances generally employed as additions to food, bringing into operation those digestive faculties of the stomach which might otherwise remain dormant when such incongruous substances as sugar and one of the principal ingredients of fish are introduced together into the stomach. Mr. Fairthorne also states that the following forms a most palatable mixture, which is readily taken by the patient: Liebig's extract, ½ ounce; extract of celery seeds, ½ fluid dram; vinegar, 1 fluid ounce; water, 2 fluid ounces; cod liver oil, 5 fluid ounces. The extract of beef is to be dissolved in water, and the oil and vinegar to be added and shaken well together with the extract of celery.

**SINGULAR MISHAP.**—A Rochester shoe-cutter who had his hand caught in some machinery, placed a cobweb over the wound to staunch the flow of blood. The web contained a small spider, which stung the man so severely, that his whole arm has swollen to twice its natural size.

## TABLE OF CONTENTS.

EDITORIALS.—Notes of a Trip to Yosemite, No. 2,  
377; The Telegraph in the Arctic; The Gold Gravel  
of North Carolina, 380; Passing Events; Mineral on  
Land Grants; Nitrates in Nevada; Contributions to the  
Geology of California; Locating Gypsum, 378; A Cur-  
ious Amalgamator; Academy of Sciences; Filing Mining  
Claims on Sunday; Now Ditching Flow; Gre Sampling,  
369; Our Arizona Edition, 376; Solution of Silver  
in Hypo, 377.

ILLUSTRATIONS.—Sperry's Mammoth Groves  
Hotel, Calaveras Grove; Section of Original Big Tree,  
Calaveras Grove, 378; Dickson's Amalgamator; Has-  
kin's Patent Ditching and Excavating Plow, 369.

CORRESPONDENCE.—The Owens River Country,  
370.

MECHANICAL PROGRESS.—Iron and Steel;  
The Strength of Wrought Iron Columns; Value of Experi-  
ments; Mechanical Terms, 371.

SCIENTIFIC PROGRESS.—Faraday's Electro-  
Chemical Researches; Late Observations on Jupiter,  
371.

THE ENGINEER.—The Second Bridge between  
New York and Brooklyn; Flooding the Sahara, 375.

USEFUL INFORMATION.—Glass-Coated Tin  
Plates for Canning; A Filler for Porous Hard Woods,  
375.

GOOD HEALTH.—How to Dress the Children; Gri-  
glin of Diphtheria, 375.

MISCELLANEOUS.—Copper Smelting—Its History  
and Processes.—No. 3; Roasting on Mineral Land  
Cases, 370; An Injunction Against Hydraulic Mining;  
No Double Taxation in California, 376; Road Laws,  
378.

NEWS IN BRIEF on page 381 and other pages.

## Passing Events.

The most important event of the week has  
been the shutting down of a number of the hy-  
draulic mines of this State, owing to an injunc-  
tion having been granted against them in favor  
of the city of Marysville. We give full details  
of the decision in another column. At Smart-  
sville the foremen and miners of the Excelsior  
Water Mining Co. were discharged. Several  
hundred men, a majority of whom have large  
families to support, will be obliged to seek other  
homes, unless the mining is resumed. The loss  
to the laboring class will be \$25,000 per month.  
The feeling is very intense in the regions af-  
fected, and is the general topic of conversation.

The State has been visited by a refreshing  
rain, which, while it may have slightly damaged  
some of the hay, has laid the dust and puri-  
fied the atmosphere.

In another column we announce a most im-  
portant discovery—no less than the finding of  
beds of nitrate in Nevada. It is highly proba-  
ble that similar discoveries will follow this, as  
there are many other parts of Nevada and of  
this State favorable to its formation. Probably  
Arizona may also be found to produce nitrates.

The decision of the Supreme Court with  
reference to double taxation, which we give  
elsewhere in this issue, is one which will give  
satisfaction, as settling a very important point.

In Europe the advices tell us that Irish land  
troubles still continue, with no present prospect  
of any abatement.

The action of the Board of Regents of the  
University of California, with reference to the  
changes in the faculty, is an absorbing topic  
just at present. President Le Conte has re-  
signed the presidency, but will remain in the  
Chair of Physics. Secretary Stearns, of the  
Board of Regents, has also resigned. The sala-  
ries of the professors have been reduced, and  
those of the assistants have been raised, and  
several professorships have been declared vacant.

## Our Arizona Edition.

We shall issue next week a 36-page edition of  
the MINING AND SCIENTIFIC PRESS, devoting its  
space largely to the interests of the great min-  
ing regions of Arizona. With it we shall pub-  
lish a large double-page map of Arizona, show-  
ing its mining districts, mines, reservations,  
railroads, towns, and all geographical features.

We shall also devote considerable space to  
the electric light system as applied to mines,  
with numerous illustrations. We have had  
prepared a fine engraving of the latest improved  
copper-smelting furnace, now in use in many  
places on this coast, and have quite a number  
of illustrations of general interest. In fact,  
the MINING AND SCIENTIFIC PRESS of next week  
will be a more than usually valuable one for  
miners.

We aim to continually improve this journal  
and keep pace with the times in all matters re-  
lating to mining and metallurgy in particular.

The PRESS is now the oldest of the mining  
journals of this country, which is something to  
be said in view of the great number of mining  
papers now being published.

We began over 20 years ago to devote our  
columns to the mining interests, and we have  
continued to do so ever since.

We shall print a very much larger edition  
than usual next week, and shall send a copy of  
the PRESS to all the quartz mills on the coast,  
in addition to the numbers that will be dis-  
tributed elsewhere. It is scarcely necessary to  
say that this will be a first-rate opportunity for  
advertisers. And it will, moreover, be a good  
time for those who are not subscribers to be-  
come so, as a new volume will commence in two  
weeks more.

## Mineral on Land Grants.

Nearly every California miner will recollect  
what trouble has been made with Spanish  
grants in various parts of the State. The fa-  
mous Mariposa Land Grant case is familiar to  
most old timers. The trouble in Julian district,  
San Diego county, over the Cuyamaca grant,  
was similar, though as it turned out the grant  
did not take in the prominent mines.

The trouble to which we allude is that the  
owners of Mexican grants, which usually cover  
very large areas of land, have not only title to  
the land, but to the minerals it contains.

Therefore, any one finding minerals within the  
boundaries of these grants, had to pay the  
grant owner for it or have it taken from him  
although a bona fide discoverer. In a num-  
ber of instances even have developed mining  
property without knowing they were on a grant,  
and then had to give up their claims in the end.

People going to New Mexico to prospect will have  
the same trouble we had here for the same con-  
ditions exist there as will be seen by the following  
paragraph from the *Cimarron News and Press*.  
"However much one may deplore the fact that  
the mineral was not reserved by the United  
States in its confirmation and patent of land  
grants in this Territory, there seems no doubt  
that this was not done and that the title of con-  
firmed grants to mineral is good and unassail-  
able. It is probably true that in many cases  
the United States could, under the terms of the  
Gadalupe Hidalgo treaty, have followed the  
custom of the Mexican government in reference  
to mineral lands and reserved the mineral to  
themselves. Had they done this the owners of  
grants, not by terra mineral, would probably  
have had no redress, but the Government fol-  
lowed, instead, the custom long established in  
the United States and conveyed with the land  
all the title of the United States to everything  
within and above the ground. It is probable  
that this custom may be changed by legislation  
next winter, and that in grants hereafter con-  
firmed the mineral will be reserved by the Gov-  
ernment in all cases where such reservation is  
possible. It is an error to suppose that New  
Mexico and California are the only parts of the  
United States where this same question of owner-  
ship of mineral on lands supposed to be agri-  
cultural has arisen. The farmers of Southwest-  
ern Missouri found themselves wealthy only a  
few years since when lead was discovered there.  
The farmers and fishermen of Maine and the  
farmers of North Carolina and Georgia are also  
now reaping a golden harvest they have not  
sown and of whose existence they did not, until  
recently, dream. There is no question among  
miners in these localities as to the absolute  
ownership of the mineral by the owners of the  
soil, and there will be none in this Territory  
within a few years."

THE Wood river prospects, according to the  
Idaho *World*, are going into the hands of capi-  
talists at a rapid rate, and the discoverers are  
receiving handsome sums for their finds. The  
mine there, instead of "petting out," as was  
feared they would do, continue to show up bet-  
ter as they are gone down on, and the develop-  
ments that have been made are sufficient to  
prove their permanency almost beyond a doubt.

## Nitrates in Nevada.

## A Highly Important Discovery.

One of the most important mineral discoveries  
ever made on this coast has just been brought to  
light in Nevada. It is, in fact, one of national  
importance if the extent of the deposits be at  
all as represented and supposed. It is no less  
than the discovery in Nevada of large beds of  
nitrates, similar to the famous ones Chile, from  
which that government has derived large reven-  
ues, and which have been of so much use to the  
world.

Some small pieces of nitrates were found at  
Brown's station on the Humboldt desert about  
a month since. These were sent to our State  
Mineralogist for examination. His remarks on  
the subject, when published, called attention to  
the peculiarities of the mineral, and led to the  
present discovery.

On the 31st ult., John Eitel, assayer, of Sac-  
ramento, wrote as follows to Mr. Hanks, the  
State Mineralogist of California.

"The house of Booth & Co. have left a salt with  
me, which, I believe, was sent to them from  
some part of Nevada, the parties desiring to  
know its commercial value. I made a qualita-  
tive analysis of it and found it to be similar to  
Chile salt-peter. As I understand it, the com-  
mercial value depends on the nitrate of soda  
contained in it, which, however, can only be  
ascertained by taking a quantitative analysis, and  
for this they do not like to pay, it seems. I  
either read, or some person informed me that a  
similar salt was submitted to you for analysis.  
Therefore I concluded to inquire what you  
think the material is worth per pound in large  
quantities."

After the receipt of the letter, Mr. Hanks  
examined the specimens, and wrote as follows:

SAN FRANCISCO, June 2.

JOHN EITEL.—Dear Sir: The substance of  
your letter, dated May 31, is very interesting.  
Nitrate of soda does not exist in nature in a  
pure state. In Chili and Peru it is extracted by  
solution in water from very low grade material  
and recovered by evaporation and crystalliza-  
tion. Commercial nitrate of soda is quoted to-  
day at 34 cents per pound—equal to \$70 per  
ton.

I would like to be put in communication  
with the parties who have discovered the de-  
posit from which your samples were obtained.  
The discovery of a large quantity of any nitrate  
in the locality you indicate would not only be  
of great importance to the Pacific coast, but to  
the whole United States, and would like to  
have the opportunity of investigating it. Very  
truly,

HENRY G. HANKS, State Mineralogist.

In reply to the above the following was re-  
ceived from the owner of the deposit:

LOVELOCK, C. P. R. R., June 6, 1881.

HENRY G. HANKS, Esq.—Dear Sir: In re-  
ply to your letter of the 2d ult., addressed to  
Mr. Eitel, of Sacramento, I would state that  
there appears to exist in a certain place about  
eight miles from here a large quantity of min-  
eral similar to the sample furnished you by Mr.  
Eitel. We have located the ground according  
to the mineral laws of the United States, and  
will do something toward developing it. And  
will be very glad to communicate with you in  
the matter. Will forward to you samples of  
the mineral, together with description of for-  
mation, character of rock, etc., or, in fact, any-  
thing you desire, in order to get your assist-  
ance toward awakening an interest in this heretofore  
neglected subject. Would be pleased to  
hear further from you, and will take pleasure  
in sending you any sample or statement in my  
possession. Hoping to hear from you soon, I  
remain, yours respectfully, D. B. MERRY.  
Mr. Hanks has verified the result of the analy-  
ses, and finds the mineral to be a very rich ni-  
trate of soda. He informs us that in his opin-  
ion this is one of the most important discov-  
eries ever made on this coast. He has no doubt,  
moreover, that other similar deposits will be  
found, as large regions of Nevada and Califor-  
nia are of a formation suitable for its existence.  
Many years ago he predicted the discovery of  
nitrates in the southern part of this State, but  
as yet no deposits have been found. It may be  
that the mineral has been overlooked by pros-  
pectors through lack of knowledge concern-  
ing it. We shall know in a short time more  
particulars regarding the extent of the find.

The nitrates are used as a source of nitric  
acid, as fertilizing agents, and for a number of  
purposes. Without them we should not be able  
to manufacture gun powder, as the "salt-peter"  
is a nitrate. With large beds in our own coun-  
try, the Government, in case of war, would  
have all the articles for the manufacture of pow-  
der within its own territory, which has not  
been the case hitherto.

THE MOUNT POTOSI DIRECTORSHIP.—In the  
matter of the application of G. F. Glover, to  
set aside the election of Directors of the Mount  
Potosi Con. M. Co., Judge Sullivan, of the Su-  
preme Court, decided that the election of A. J.  
Holmes, S. B. Boswell, Culvert Mead, R. S.  
Wilson and C. G. Strong as such Directors, on  
the 22d of September, 1880, was illegal, and  
continued the hearing of the question of the  
validity of the election of Montague K. Ste-  
venson, James M. Day, Henry Lowden, N. D.  
Thayer and J. H. Frish as Directors, on the 2d  
of May last, until the 16th of July.

## Contributions to the Geology of California.

## New Series.

H. G. HANKS, STATE MINERALOGIST, CALI-  
FORNIA:—Recognizing the importance to the  
State of the work in which you are engaged,  
and the gratifying measure of success which has  
already attended your efforts to establish a per-  
manent geological and mineral collection, I take  
pleasure in offering you a series of written con-  
tributions upon the minerals and the geology of  
California. As these contributions will be based  
upon the observations I make in traveling  
through various portions of the State, and will  
often be written during the journeys, they will,  
of necessity, be somewhat desultory and in-  
formal, but I hope they will assist in making  
the varied and interesting geological features of  
California better known.

## New Mineral Localities.

ERTHYRITE: Cobalt Bloom.—In minute  
mamillary incrustations, showing, when  
broken, radial aggregations of silky, fibrous  
crystals. Color: deep carmine or rosy-red, also,  
peach blossom red. Streak, the same color, but  
is blue after the mineral has been heated. It  
gives the usual reactions for cobalt, arsenic and  
water. Occurs, also, in massive earthy aggre-  
gations, of small fibrous crystals of a rose-pink  
color. It is associated with an ore of silver and  
cobalt in dark-colored earthy masses, a mechani-  
cal mixture, assaying at the rate of 5,000 to  
6,000 ounces of silver to the ton, but the precise  
nature of which is not yet ascertained, in a  
gangue of heavy spar, containing, also, nodular  
masses of chalcocite (yellow copper ore.)

From the Bernardino range, Southern Cali-  
fornia. This is believed to be the first observa-  
tion of the occurrence of this species in the  
United States.

RUBELLITE: Rose-colored tourmaline.—This  
very interesting mineral is now observed for  
the first time in California, in the form of long  
alender crystals from one-sixteenth to one-  
eighth of an inch in transverse diameter, with  
the usual triangular section. Color, a beautiful  
rosa-pink, contrasting well with the matrix of  
white lapidolite.

When ignited the color disappears and the  
mineral becomes perfectly white. Infusible.

Locality, Bernardino range, southern Cali-  
fornia.

LEPIDOLITE—occurs with the above in mas-  
sive aggregations of minute pearly scales, both  
colorless and purple-red in color. It is trav-  
ersed by the crystals of tourmaline. It fuses  
readily to a white enamel and colors the flame  
next to the assay a dark crimson-red for a mo-  
ment.

CASSITERITE: "Wood Tin."—A single speci-  
men of wood-tin, a segment of a botryoidal mass,  
with concentric structure and dark brown in  
color, was found by Mr. Thomas Lana, of La-  
porte, in the bed of the Middle fork of the  
Feather river, about three miles above Big Bar,  
Plumas county. The mass is about 8 of an  
inch in diameter, and closely resembles the  
wood-tin brought from Durango, Mexico, and  
that found in Idaho. The attention of placer  
miners should be directed to this, as other frag-  
ments may be found in cleaning up sluices, and  
thus lead to the discovery of the source of this  
valuable ore of tin.

BORNIK: Variegated Copper Ore.—This  
beautiful ore of copper is found upon the claim  
of Mr. A. J. Ford, at Light's Canyon, Plumas  
county, in a vein affording massive specimens  
three inches or more thick. In the same re-  
gion there are veins of yellow copper ore and of  
massive Hematite.

Wm. P. Blake,

San Francisco, June 3, 1881.

(TO BE CONTINUED.)

## Locating Gypsum.

Gypsum is not a mineral within the meaning  
of the Mining Act. In the opinion of the Com-  
missioner of the Land Office, lands of the pub-  
lic domain containing deposits of gypsum, which  
is of similar formation to limestone, are not  
subject to disposal under the mining act. Limestone underlies a great portion of the ter-  
ritory west of the Mississippi river, and to re-  
serve such lands as mineral would entirely pre-  
vent its development for agricultural purposes.

The term "mineral," in its most compre-  
hensive sense, includes all inorganic substances  
having a definite chemical composition, and so  
applied in the construction of Section 2,318 of  
the Revised Statute, would subject all the pub-  
lic domain to sale under the Mining Act. A  
more reasonable construction of said section  
will hold it to embrace only such lands as con-  
tain valuable deposit of metals, and other en-  
richments which give the same special value greater  
than that of land containing limestone deposits  
in any of its forms.

LIBRARY CONSOLIDATION.—At a recent meet-  
ing of the Board of Trustees of the Mechanics'  
Institute, a committee previously appointed re-  
ported that they had conferred with a committee  
from the Mercantile Library Association upon  
the advisability of uniting the institutions. They  
reported that both committees considered that  
the plan was a good one. Next Tuesday  
another meeting will be held to finally decide  
upon the proposition.

## Notes of a Trip to Yosemite.—No. 2.

[Written for the Press by O. H. S.]

This morning we made an early start and took our last views of the wonderful valley from the top of the stage as we rolled rapidly down the valley behind a six-horse team, and we were soon climbing the grade of the

## Big Oak Flat Stage Route.

After reaching the top of the grade the road winds rapidly down through the forest; and the rain of the previous day had extended a few miles beyond the valley, so that the air was fresh, and with the smell of the pines and the many beautiful wild flowers, it was extremely pleasant. During the ride we cross the pipes of the Golden Rock Ditch & Flume Co. This property has lately changed hands, and the present owners intend to use most of the water in future in working claims of their own. They have been prospecting some ground near where the stage road crosses the pipe, but have now closed down and will clean up, and as soon as work can be completed for the purpose, they will go to work extensively upon other ground of their own some 10 or 15 miles lower down.

Passing through Garrote and Big Oak Flat, formerly extensive mining camps, we reach Priest's hotel at 4 o'clock and stop an hour for dinner, after which we are driven down the two miles of Rattlesnake hill, at the foot of which we are transferred to another coach, driven today by Mr. J. H. Shine, one of the gentlemanly proprietors of the Nevada Stage Co. Crossing the Tiolumne at Haewell's ferry we enjoy the evening drive along the banks of the river through Jacksonville, and over a picturesque road to Chinese Camp, which is the usual stopping place for the night, but Mr. Shine offered to carry us on 11 miles further to Sonora in his own private carriage if we desired, and we were soon on the road again, reaching Sonora late in the evening, tired enough to enjoy the rest we took at the City hotel.

## Sonora and Columbia

Were two of the largest and most noted towns in the southern placer mine of California. They are but about four miles apart, and upon the flat between them upwards of 8,000 men are estimated to have worked in the rich placers which were found there. To-day the projecting rocks and pile of stones, bare and desolate, look as if the country had been subjected to some terrible convulsion of nature. For a long time after the first exhausting of the diggings, these places went down steadily like the other mining camps, but they now show signs of revival, especially Sonora. This is more especially due to the discovery of rich quartz ledges, among which the one called the Bonanza hill, situated almost in the middle of the town, is the most noted.

This mine is known as a pocket mine; and from its outcroppings it is supposed that most of the gold formerly found in the lower part of Sonora was derived. It was first discovered sometime early in the fifties, and was partially opened and worked at different times by various parties, who afterwards abandoned it. It is estimated that some hundreds of thousands of dollars had been taken from it in all before it fell into the hands of its present owners, who have developed its great wealth during the past five years. The mine is at present principally owned by Divoll & Bray, of Sonora. It runs down on an incline between 30° and 40°, about 260 ft., and is said to be paying enormously, although its owners are inclined to keep their business to themselves. One single shipment from this mine was made by express of 983 lbs. of gold, which certainly gives good grounds for the rumour.

A number of other promising mines are being opened, some \$6,000 or \$7,000 having been recently taken from the Colby mine which is but a short distance from the Bonanza Hill, and is thought by many to be upon the same ledge.

The road from Sonora to Murphy's leads through a hilly but pleasant country, passing close to a stream where there is a natural bridge about 240x100 ft., and from 50 to 60 ft. high. The arch through which the water flows varies in height and width, and time enough is given by the driver to examine it thoroughly. About four miles from Columbia a large cave has been discovered. It has not been wholly explored, but its interior is filled with stalactites and all the wonderful and fantastic formations common to these limestone caverns; it is said to be the finest ever discovered upon this coast.

## Murphy's

Is another pleasant little town where travelers often make a stay, but we only waited for our conveyance to the Big Tree, which proved to be a two-horse buggy, as the regular stage was full. Leaving Murphy's at half-past four in the afternoon, we enjoy a pleasant drive through a forest of trees increasing gradually in size, until when we pass between the "Two Sentinels," which lean above the road a short distance from the Mammoth Grove hotel, we are almost prepared for their great size. Not quite, though, for we are startled at the great shadows as we pass between them in the deepening darkness of the night, which is fast closing in as we drive up to the steps of the hotel and alight to prepare for dinner.

## Big Tree Grove.

The temperature was quite cool on the evening of our arrival and upon the following morning, but not enough to be uncomfortable.

Sperry's hotel has a very fresh, clean appearance, and is well arranged for the quiet and rest of guests. A great change is noticeable in the climate here from any of the places hitherto visited. It is said to be an excellent thing for those needing a change of climate to stop for a month or more. We certainly found it a very restful place after the excitement of the previous week and the roughness of long stage journeys.

The morning of our first day was spent in the grove near the hotel, which contains 93 of the sequoias, not including young ones. Paths are made among the trees so that all which are notable for size or any peculiarity may be easily visited. These trees are scattered through a forest of sugar and yellow pines, many of which are 275 ft. in height, and 10 or 11 ft. in diameter.

This bark was taken to England and set up for exhibition, but its size was so tremendous that it was treated as a Yankee humbug and was believed to have been ingeniously constructed for the purpose of deceiving those visiting it. The tree is, of course, dead, and will doubtless come down during some heavy storm within a few years. The Father of the Forest, already fallen when the grove was discovered, measured 112 ft. in circumference at the base and still shows a length of 300 ft. to the point where it was broken by falling against another tree. At this point it is 16 ft. in diameter, and it must originally have been 450 ft. in height. We walked 200 ft. through the immense cavity which is burned through its center, to a point where we could emerge through a knot hole two and one-half ft. in diameter.

SPERRY'S MAMMOTH GROVE HOTEL, CALAVERAS GROVE.

ter, and would be considered enormous, but for the comparison with the sequoias, which make the largest of them look small; but here, as at Yosemite, we seem to have found something too grand for our immediate comprehension. We listen to a statement of the size of the trees, walk up and examine them, and climb upon the

eter, formed by the breaking off of a limb. One is struck in examining the fallen trees at the comparatively small size of the roots, the apparently entire absence of tap roots, and the shallow cavity left by their uprooting. The wonder is that they stand as long as they do. The cones from these trees are ridiculously

SECTION OF ORIGINAL BIG TREE, CALAVERAS GROVE.

fallen ones, looking down from an elevation of upwards of 30 ft., and yet fall. We have nothing of ordinary size to which we are accustomed for comparison; but when we remember that one of these trees, if set upon an ordinary city house lot would entirely cover its width, and project eight ft. upon the next lot, we begin to appreciate their size. Our party of 11 stood around one of the trees with extended arms, just touching the tips of our fingers, but the two ends of our line could not get within sight of each other; in fact the line would not reach much more than half around some of the trees. The bark which has scaled off the trees for hundreds of years has formed mounds three or four ft. high, close about their trunks; and the best idea of their vast size may be obtained by walking around the tree upon this mound, close to the trunk. Most of these trees have been named after scientific men—generals, divines, and men more or less famous. The one called the Mother of the Forest, from which the bark was stripped to the height of 116 ft., is the termination of the walk northward.

small, being but about 2 inches long, while all around the ground is covered with cones from the pines 15 to 18 inches long, and 5 or 6 inches in diameter. Almost all the trees show evidence of destructive fires, some of them having enormous cavities burned into them and extending upward from 50 to 100 ft., leaving apparently but a mere shell to support the round upper portion and branches, yet these trees appear as healthy and vigorous as if sound throughout.

## South Grove.

Our morning excursion terminated in time for lunch, and the afternoon was spent in various ways. On the following morning horses were waiting us after breakfast had been disposed of, and under the guidance of Abel Richey, the well-known guide, who had accompanied us upon the previous day, we started for the South Grove. The way led over a ridge which separates the Big Tree creek from the north fork of the Stanislaus. From this elevation we obtain a fine view of the Dardanelles, distant peaks of the Sierras, which tower to the height of

12,500 ft. After a few moments we descend the winding trail through Squaw hollow to the haaks of the Stanislaus, crossing upon a rough bridge, which spans the stream just at the foot of a pretty cascade which comes tumbling down among the rocks in a mass of foam. From this point we ascend to another crest from which we have a fine view of the Basaltic cliffs opposite. Continuing our journey we finally descend to the banks of Beaver creek where we called a halt to allow some ambitious disciples of old Isaac Walton to try their luck in this stream which is deservedly famous for its trout.

The south grove, which we soon reached, is much larger than the one at the hotel, extending about three and one-half miles, and contains a great number of very large trees. In the base of one is a cavity which will contain 16 horses and their riders. The ravages of fire are also seen in this grove, but only upon the Sequoias. The immense pines, some of which are 12 ft. in diameter, show no marks, and as they are evidently of a later growth, the inference is that these fires occurred before the pine forests started. What might have been the appearance or extent of the sequoia forests previous to that time, must always remain a matter of conjecture.

We rode alongside of one which had fallen long since, and the cavity being upon at the top of the tree lay, made it look like an immense canal boat. In other places we ride through or between trees which have burned, until we reach a tree having a cavity in its base 21 by 16 ft. This tree is called Smith's cabin, from an old trapper who resided in it two years, the apartment being divided into a kitchen, dining room and bedroom. Near this cabin is "Goliath," a tree which fell some years since and is the largest of the fallen trees.

Two hundred and sixty-one ft. from the base, it measures 45 ft. in circumference. This grove has many beautiful and interesting features beside the great trees, and one day is hardly sufficient to dispose of the whole.

The next day completed our stay in this delightful place, and we turned our steps homeward wishing that we could spend a month in the pure mountain air and among the grand old trees which give a sense of rest and quiet very different from the excitement of the valley of the Yosemite, and a great relief after them.

We reached Murphy's that evening, and, leaving early the following morning, passed through Vallejos, Angels, Altaville and other small towns, reaching Milton and railway travel shortly after ten in the morning.

## An Interesting Route.

This trip is one which should be of great interest to the Eastern or foreign tourist, who is anxious to see as much as possible of California in a short time. It embraces some of the most interesting of the gold diggings, once so thickly populated and so fabulously rich, and one can still see enough work going on to understand the general operation of gold washing. Here are laid many of the scenes made famous by the pen of Bret Harte. Who does not remember the abrupt and disastrous termination of the society upon the Stanislaus, as related by Truthful James, of Table Mountain? It embraces two of the greatest wonders upon this coast, and enough of lesser interest to profitably occupy two weeks, more or less. The hotels are well kept, and careful of the comfort of guests, and the stage company certainly does all in its power to prevent delays and annoyances, and the kindness and courtesy of proprietors and employees, goes far to relieve what is at best a hard trip.

## Solution of Silver in Hypo.

The statement that silver chloride dissolves in a solution of calcium hyposulphite is not strictly accurate. It is decomposed, exchanging constituents with the calcium salt, forming calcium chloride and silver hyposulphite. The latter combines with another portion of calcium hyposulphite and forms a double salt, silver calcium hyposulphite, which is very soluble in water.

Mr. C. H. Aaron, in his "Leaching Gold and Silver Ores," says that if calcium pentasulphide is added to such a solution in equivalent proportion, one-fifth of its sulphur combines with silver to form silver sulphide, which is precipitated, together with the remaining four-fifths of the sulphur. The oxygen, and so-called hyposulphuric acid, which were combined with the silver, combine with the calcium of the decomposed precipitant. Thus the portion of the solvent which was decomposed by silver chloride is reproduced.

From this it follows that, for every atom of silver extracted from the ore, and precipitated by polysulphide, the solvent gains a molecule of calcium chloride, without, however, having ultimately lost any hyposulphite, and this is the reason why the density of the solution ceases to be an index of its solvent power. So far there is neither a loss nor a gain of calcium hyposulphite in the dissolving solution, but, as stated elsewhere, the precipitant always contains a quantity of that salt in watery solution, which being added to the solvent, increases its volume without impairing its strength, unless the precipitant is too much diluted.

In practice the increase or diminution in strength and volume of the solvent depends on the care exercised in saving as much of it, with as little addition of wash water as possible, and in having the precipitant sufficiently concentrated. Kustel gives 6° Beaume, as a minimum density for the latter.

## Road Laws.

One of the special subjects set before the last Legislature was the enactment of a general road law. They framed such a law, but it was so liable to place city property owners under the feet of jobbers and robbers that the Governor promptly vetoed it, and the Legislature was content to let the thing die. It ought not to be a hard task to devise some system by which our State could have good roads without endangering the property of those who dwell on city streets. There are, however, so many designing men waiting to get their hands on other people's money, that it seems hard to make any proposition for the general good, without leaving loop-holes through which private greed may enter to the public detriment.

It seems now that so far as road making is concerned we return to first principles and are able to act only under the old provisions of the Code. The *Contra Costa Gazette*, in reviewing this subject says:

The road law passed by the previous Legislature for application to counties of the "second-class," and which, since its passage, has been assumed to be the law applicable to this, as being one of that class, is probably unconstitutional in not having been made of general application. The question of its constitutionality has not, it is true, been determined, as it has not been brought before the courts. There can, however, be little doubt that when it is it will be declared invalid. It is safe, therefore, in our county administration of road affairs, to assume that we have really no valid road law but that enacted and made specially applicable to the county before the adoption of the new Constitution, and which, under repeated rulings of the Supreme Court, remains in force until altered or repealed by some valid enactment of the Legislature. The special law referred to, is, in all its essential features, identical with the general road law of the Political Code, and there is no action called for here in road matters that may not be taken in conformity with the general code provisions, so far as any question of its validity can be raised.

The remarks above are made with special reference to Contra Costa county, but will apply to most of our leading interior counties. As there will be no session of the legislature until 1883, the making of roads will have to proceed under previous methods and these should be used as far as possible, for the making of good roads is the key to the development of our State, and should not be disregarded.

Walker Bros',  
Wood-Working  
Machinery.  
SAN FRANCISCO  
TOOL COMP'Y,  
Agents,  
21 Stevenson Street,  
SAN FRANCISCO.

L. P. DEGEN.

## COKE. PATENT. COKE.

This COKE is exclusively used by Prof. Thomas Price, in his assay office, by the Selby Smelting and Lead Co., Prescott, Scott & Co, Risdon Iron and Locomotive Works and others in this city. Large supplies are regularly forwarded to consumers in Salt Lake and Nevada, to the Copper Queen Mining Co., Longfellow Copper Mining Co. and other consumers in Arizona.

The undersigned are in receipt of regular supplies from Cardiff, Wales, and offer the COKE for sale in quantities to suit purchasers.

BALFOUR, GUTHRIE & CO.,  
316 California St., San Francisco.

## THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

## HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

## MOREY &amp; SPERRY,

MANUFACTURERS OF

## Gold and Silver Grinding and Amalgamating Machinery

HOWLAND'S PULVERIZER Takes the Place of the Cumbrous Stamp Mill and can be put up in one day ready for work.

IT HAS BEEN FULLY PROVED AND TESTED.

It weighs complete, 7,000 pounds. It costs \$1,500 ready for the belt. Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charge or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies Iron Work complete for Wood Frames, also

SPERRY'S  
WROUGHT IRON FRAME  
FOR STAMP MILLS.

Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.

MOREY & SPERRY—Warehouses, 92 and 94 Liberty St., N. Y.

## LEFFEL'S IMPROVED WATER WHEEL.

PRICES REDUCED!

PATENTS REISSUED 1868.

The "OLD RELIABLE" with improvements, making it

THE MOST PERFECT TURBINE NOW IN USE.

Comprising the Largest and the Smallest Wheels, under both the Highest and Lowest head used in this country. Our new Illustrated Book sent free to those owning water power.

Those improving water power should not fail to write us for New Prices, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address

JAMES LEFFEL & CO., Springfield, Ohio,  
and 110 Liberty St., N. Y. City.

PARKE & LACY, Sole Agents, 21 and 23 Fremont St., S. F.

## Pacific Rolling Mill Co.,

SAN FRANCISCO, CAL.

MANUFACTURERS OF

## RAILROAD AND MERCHANT IRON,

ROLLED BEAMS, ANGLE, CHANNEL AND T IRON, BRIDGE AND MACHINE BOLTS, LAG SCREWS, NUTS, WASHERS, ETC., STEAMBOAT SHAFTS, CRANKS, PISTONS, CONNECTING RODS, ETC., ETC.

Car and Locomotive Axles and Frames, and Hammered Iron of Every Description.

HIGHEST PRICE PAID FOR SCRAP IRON.

Orders Solicited and Promptly Executed.

Office, No. 202 Market St., UNION BLOCK.

RICHARD C. REMMEY, Agent,  
Philadelphia Chemical Stoneware Manufactory.

1100 E Cumberland St., Philadelphia, Pa.

Manufacturer of all kinds of Chemical Stone Ware for Manufacturing Chemists. Also, Chemical Bricks for Glover Towers.

1851. DEPUTY U. S. MINERAL SURVEYOR.

1881. Surveys for Location or Patent. Maps and Plans Drawn. Mining Properties of all kinds examined and careful reports made of the same. Consultations on Mining Investments. Address, THOS. W. REECE, CIVIL ENGINEER, Oroville, Butte Co., Cal. References given and required.

SCARCE GOODS.—Books, Photos, &c. Samp. Catalogue 3c. Paris Book Co., Chicago, Ill.

## INGERSOLL ROCK DRILL.

PRICES REDUCED.

Parties requiring Drills can get them at agents' rates by applying to

GEO. R. FOARD,

Sole Agent for Pacific Coast.

No. 18 First St., S. F.

The only Depot where Standard Drills and Duplicate Parts can be obtained.

EXCELSIOR

BLASTING POWDER

MANUFACTURED BY THE

Excelsior Powder Company.

This is no so-called "safety" Powder, but a powerful ex-  
plosive, and as safe to handle and use as any nitro-glycerine  
Powder on the continent. There is no headache or nausea  
in the use of this Powder, as the noxious fumes are entirely  
done away with. It is put up in cartridges of any size to  
suit consumers and is exploded with cap and fuse, the same  
as any other high explosive. The following testimonials is a  
sample of hundreds of the same tenor being constantly re-  
ceived:

GOLD HILL, August 17, 1880.

AGENT EXCELSIOR POWDER CO.—Dear Sir:—I have used  
your Powder in test cement and hard blasting rock, and find  
it superior to any Powder in use on the Coast. It does  
its work effectually, and does not leave the person using it  
with a severe headache, like the other Powders out to the ma-  
jority of miners. In recommending it I would suggest, give  
it a fair trial and I am confident it will speak for itself.  
Wishing your Company success,

I am respectfully yours, etc.,

GEORGE CLARK,  
Foreman Sierra O. and S. M. Co

dress, W. T., care of Dewey & Co., S. F.

### The Telegraph in the Arctic.

(Read before the California Academy of Sciences by JAMES GAMBLE, General Superintendent Western Union Telegraph Company.)

A few weeks ago I made a suggestion that the telegraph be used in Arctic explorations. The views I expressed in relation to the matter were published in the *Evening Bulletin* of this city. They have elicited considerable attention and a good deal of comment, particularly in the East. The plan I proposed was in substance as follows:

To use light steel wire, say number 20 gauge, weighing about 20 lbs. to the mile. The wire, coiled on reels, could be hauled on sledges, either by men or dogs, over the snow or ice, paying it out as the advance exploring party went along. By this means the party would keep in constant communication with their base of supplies. They would have no cause for uneasiness about getting lost or beyond means of rescue, as they would be able at any moment to call for aid. With this feeling of the certainty of relief in case of accident, they would not hesitate to push their explorations, to a distance far beyond what would be considered safe in the absence of means of telegraphic communication with the main body. And should any accident happen to the advance party of explorers, or should they require a further quantity of supplies, the line of wire would serve to guide those going to the rescue straight to the spot where the explorers were camped. It would also serve as a guide for their return, materially lessening the chances of danger to life and loss of the party. Having established a base of supplies at some central point there would be nothing to prevent several exploring parties being sent out at the same time in different directions, they reporting each night to the central station the progress and observations made during the day. Directed in this way, the practicability of one route over another could, from the telegraphic reports sent in, be determined upon and much time that would otherwise be wasted in vain endeavors to make way over barriers of ice be saved.

As hard frozen ground, dry snow or ice, is a perfect insulator, no poles to string the wire would be required. It could be paid out on the snow or ice by the party as they went along. The generally accepted theory of those familiar with the Arctic regions, is that the ice is seldom more than six or seven ft. in thickness—Captain Hooper, in his report, corroborates this—so that by boring through it with a common drill, or through frozen ground, there would be no difficulty in obtaining a good ground connection to complete the electric current. It would not be necessary to carry any battery material. One main battery at the central station would be all that is required. For a distance of 100 to 150 miles telephones could be used, dispensing with practical telegraph operators. Still, it might be advisable to have some of the party possessed of a practical knowledge of telegraphy.

At 20 lbs. to the mile, 100 miles of wire would only weigh 2,000 lbs. It could be wound on reels in size easy to handle. The cost of steel wire of that gauge is about 20 cents a pound, so that the total expense, including cost of reels, winding, etc., would not exceed \$1,000. Among those who have been good enough to notice my suggestion and manifest an interest in it, is Mr. George Kennan, of Washington, a gentleman familiar both with the telegraph and the Arctic regions, having been connected with the Collins Overland Telegraph Co. He assisted in the building of that line during the period of construction and afterwards made a journey through Siberia. In a long letter to the *New York Herald* of May 26th he enumerates a series of difficulties that stand in the way of any profitable results being derived from the use of a telegraph wire in the polar regions. His objections to the practicability of the scheme are founded as he himself states "on the inadequacy of existing transportation facilities."

It possibly may not have occurred to Mr. Kennan that an inventor, to realize his idea, does not content himself with such means or facilities as may exist, but will provide himself with those necessary to its realization if such are to be had. He says, "I understand that Lieut. Berry does not expect to take more than 25 dogs from Petropavlovsk on the *Rodgers*." If I had used only 25 men in the construction of the overland telegraph line, the probabilities are that the overland line would not be finished yet. The poles at one end would have had time to rot away before the poles at the other end could have been set. If only a sufficient number of sledges and dogs are used to carry the necessary provisions for the party, then, clearly, there will not be room for anything else. But if more dogs and sledges are used—even Mr. Kennan admits this—there would be room to carry something else besides food for the party.

And in connection with this point, he overlooks the fact that, as the exploring party advances, the load of wire is every moment becoming lighter. It is lightening up at the rate of 20 lbs. to the mile, and if the party make two miles an hour, they are unloading 40 lbs. an hour. Within a week, 100 miles of wire would be paid out. If they started out with 200 miles the different sledges could unload in part alternately so that after having accomplished 100

miles, each sledge would only be carrying a half load. When again, some had entirely unloaded they could return to the base of supplies, the wire being their guide back.

"But," Mr. Kennan says in another place, "100 miles of wire, even if it could be carried without sacrificing every thing else, would be of very little use." That, in one sense, is a mere assumption, in another, it is incorrect. One hundred miles of telegraph would have been the means of saving many a life sacrificed to Arctic explorations. Ten miles is a very long distance in the Arctic regions, more than sufficient to prevent a famishing explorer returning to his party. To show the uselessness for exploring purposes of 100 miles of wire or more, Mr. Kennan cites Lieut. McClintock's journey in 1853, of 1,200 miles, made on sledges with a party from the *Resolute*. Had Lieut. McClintock pursued this journey in anything like a straight line, he would have gone over the North Pole and down the other side. But as he did not do this, it is proper to suppose what in fact is a reality, that the 1,200 miles represent his wanderings forward and backward, hither and thither, on the ice between his leaving and return. The instance therefore cited by Mr. Kennan of 1,200 miles having been traveled and so little accomplished, so far as reaching a higher latitude is concerned, is a strong argument in favor of a telegraph wire. With it Lieut. McClintock and others who have succeeded him, would not have wasted so much time nor incurred so many risks to themselves and parties.

In point of fact, several hundred miles of wire could be taken as easily as 100 miles, the requisite number of sledges and dogs being provided—and without any difficulty whatever. Mr. Kennan says again: "It is very doubtful whether a steel wire of number 20 gauge could be unreeled from a sledge in a temperature 50° below zero without snapping at every turn of the reel." The doubt here expressed seems at first sight a reasonable one. I have, however, supplemented my own opinion on this point with that of one of the best authorities here on the effect of cold on metallic substances, and especially the effect of a very low temperature on iron, steel and other wires. Under intense cold hardened steel is undoubtedly rendered extremely brittle and will readily break when subjected to a blow. But steel wire can be annealed to a degree making it as soft as iron wire, and as easy to handle from a reel in northern latitudes as in warmer ones.

It should also be remembered that the uncoiling is not a snappy or jerky movement. It is not uncoiled any faster than the progress made by the party, and which is about two miles an hour. Moving forward steadily and not faster than two miles an hour, annealed wire could be uncoiled without any trouble or danger of snapping off.

Even in the event of a prejudice existing against steel wire, copper wire could be used. In suggesting steel, I did so simply because of its greater strength and cheapness. But did such a danger exist, as supposed by Mr. Kennan, of the snapping off of the wire at the turn of the reel under a low temperature, how was it then that the wire for those portions of the telegraph line built across Northern Siberia towards Bering strait, to connect there by means of a cable with the Collins overland line on this side was uncoiled? Several portions of that Siberian line were built and the wire strung during the winter, with the thermometer ranging down to 50° below zero, Fahr. The line running along the head waters of the Anadyr river and along the Okhotsk sea was also built, the wire uncoiled and strung during the winter months. It was the only time of the year, in fact, it could most successfully be done, it being difficult to haul the loads of wire over that part of the country, owing to the wet and swampiness of the land during the other periods of the year. Col. Bulkeley, Chief of the Collins overland telegraph expedition is my authority for this statement. That part of the line from Plover bay to Bering strait was also built during the winter. These are facts that Mr. Kennan ought to be familiar with and which, had he recollected, would have prevented him advancing such objections as he has.

Mr. Kennan is a most intelligent gentleman, but I cannot help thinking that his observations on this subject are mainly the result of his imagination, and not of practical experience in regard to the utility or inutilty of a telegraph line in Arctic explorations. You will recollect that when an overland telegraph line was first proposed in Congress it was considered impracticable. Among the earliest suggestions made was one by the Hon. Stephen A. Douglas, and notwithstanding that his plan was clearly elucidated, it was still considered an impossible scheme. The objections raised against the possibility of the construction were: Difficulty of transportation, scarcity of timber along the route, difficulty of protecting the line from Indians, and many others equally plausible and apparently well-grounded by those who made them. But in the face of all these objections and difficulties there were some who were willing to try and willing to risk their money in the construction of such a line. I need not ask you if they succeeded. You, who read in your newspapers, morning and evening, the dispatches from all parts of the world, know that they did. But it should be remembered that they not only did succeed in constructing an overland telegraph line, but that through it they also succeeded in establishing the weakness and worthlessness of all the different arguments and objections raised against it when

the idea was first suggested. But neither one nor the other would ever have been established had not a trial been made, and that is precisely what should now be done in respect to a telegraph wire in the Arctic regions.

The idea I have suggested is, I think, sufficiently important to merit a practical experiment being made. This can be done by Lieut. Berry, commander of the *Rodgers*, who honors us with his presence here to-night, and who is about to risk his own life and the lives of others in search of those who left on the *Jeannette*. If steel wire is rendered too brittle by the extreme cold, then try copper. There will not be any strain on either as strung out on the ice and there will be plenty of slack to allow for contraction. I can well understand that the greatest difficulty will be the transportation, but it is not worth while to make an effort to overcome this in order to better ensure the safety of the lives of the brave men who undertake the perilous task of exploring that unknown region? It will be impossible, from want of time, for Lieutenant Berry to have prepared a proper outfit for several hundred miles of wire. I would therefore respectfully suggest that he take with him a few miles of three different kinds, say 5 or 10 miles of steel annealed, iron, and copper wires, so as to try, during next winter, the effect of the cold on each. Telephones should also be provided, so that a practical experiment could be made of securing the necessary ground connections, etc.

Theory is not always correct; practical experiments furnish the most satisfactory proof of what can be accomplished, and the opportunity is now afforded to determine whether the telegraph can be utilized to aid in exploring the Arctic regions.

### The Gold Gravels of North Carolina.

(Read before the American Institute of Mining Engineers by W. C. KNAAB, State Geologist, Raleigh, N. C.)

When Agassiz and his party of geologists commenced their exploration of the interior of Brazil and the Amazon region, one of the first and, to the last, one of the most novel and striking phenomena which met them everywhere was the great depth of decomposed or partially decayed rock *in situ*, which mantles, and for the most part conceals, the underlying strata. The same facts strike all geological observers from the North who happen to penetrate the middle and southern latitudes of their Atlantic States. In North Carolina, *e. g.*, the entire middle and western regions, outside of the quaternary clays, sands and gravels in the east—that is, all that portion of the State occupied by the Archean and Mesozoic rocks—show everywhere this peculiarity, so new to those accustomed to glaciated surfaces. Not only do the hills and slopes, the mountain chains and spurs, present everywhere to the eye this superficial covering, but even the more level tracts and the valleys. The railroad cuts give very good exposures of this covering, and furnish, everywhere, abundant opportunities for the study of its structure and history.

Some of the more obtrusive facts are these: The thickness of this covering varies from a few ft. to 30 or 40, and often 60 and 75, and even 100 ft, and bears an obvious relation to the character of the underlying rock, being least where this is most refractory, and *vice versa*; the rock is generally near the surface in the crests of the hills. The upper portion of this earthy envelop for several ft. beneath the soil is homogeneous and structureless; but lines of structure soon make their appearance, becoming more pronounced with the depth. These lines of structure are commonly coincident with bands and ribbons of differently colored earths, which, on closer inspection, show differences in their materials also, these differences becoming more and more strongly marked as they are traced downward, until they pass by insensible gradations into the solid rock beneath. The obvious and necessary conclusions from these observations gives itself, viz., that the rocks of the region are and have long been undergoing a slow chemical decomposition and disintegration from the action of atmospheric forces, this decay being too rapid, however, to be overtaken by the abrasive and transporting power of these same agencies.

So far the general and obvious facts, plain to be read by the man that runs. A little closer inspection reveals another set of facts.

It is easily discovered that these mantles of earth and half-decayed rocks are not strictly *in situ*, but have been subjected to some sort and degree of movement, and that the materials have undergone at least a partial rearrangement in certain situations and under certain conditions. In general on the summits of the hills there has been no change, but descending the slope, however gentle, a tendency to a sorting and arrangement of materials appears, and this becomes more observable with the distance. At first the fragments of quartz and other hard rocks are sharply angular, and are distributed equally and irregularly through the mass, or in lines corresponding to the bedding of the rocks. Descending a few rods the rock fragments have "settled" somewhat; they are found more thickly strewn towards the bottom, and are less angular. Descending still further all the coarser fragments are found accumulated in a layer of cobbles or pebbles, with only the interstices filled with earth and gravel.

The obvious interpretation of these facts is that there has been a movement or flux of the earthy mass in the direction of the slope.

The difficulty at once arises how to account

for a flow of such materials with such results. The ordinary action of flowing water is, of course, excluded. The mere action of gravitation will not account for the phenomena—slipping or sliding down hill. This, doubtless, often happens on very steep declivities, but such cases are quite exceptional and are easily distinguished. The movements we are considering have taken place at every degree of inclination, from one degree and less upwards, and occasionally on a level, or even up hill.

After puzzling over these phenomena for half a dozen years, and wondering that there is no explanation in the books, or even any discussion of the subject or note of the facts, not even in Gerkie's *Great Ice Age*, it occurred to me that the only possible solution must be sought in

### The Action of Frost.

The alternate freezing and thawing of such a mass of earth must needs produce just the effects we have been considering. The earth, saturated with water, in the process of consolidation under the action of cold would, of course, expand just as if it were all water, and in thawing there would be a slight movement of the parts and particles of the mass *inter se*, and of course a settling of the heavier fragments; in other words, the movement would be the same in kind (though not in amount) as that of a glacier. These masses may be considered earth glaciers. And I have ventured to denominate this group of phenomena, and these peculiar superficial accumulations, *frost drift*. Now the ordinary glacial phenomena are wanting in North Carolina, with, perhaps, the exception of a few moraine ridges in the gorges of the higher mountains. But during the glacial period, of course, the cold must have been intense enough to account for the depth and extent of action which the theory of *frost drift* supposes.

I was led to these results from the particular Study of Gold Deposits

Of the State. They have all been formed in this way. There are probably 500 square miles of gold drifts in North Carolina. They are formed through a range of 400 miles east and west, from the lower waters of the Roanoke, near Weldon, to the extreme western border, the county of Cherokee. And they belong to all the different subdivisions of the Archean rocks of the State. The two most extensive deposits are found in the middle region, on the Yadkin and Catawba rivers, among the low ranges and spurs of the mountains. The shistose and slaty rocks, highly inclined and much contorted and dislocated, are in many places penetrated by innumerable small veins and seams of gold-bearing quartz. In the disintegration and breaking down of these rocks, and the movement of the *debris* in the manner described, it is evident that the gold particles, with the heavier crystalline minerals, will be found accumulated near the bottom of the drifts, on or near the surface of the bedrock, or "slate," as the miners call it.

### The Gold Mining of Modern Times

Began 60 years ago in this region from the accidental discovery of a 23-lb. nugget by a boy in one of the streams of this region. Most of the simple and effective appliances now in use everywhere for the separation of gold from such deposits—the long tom, the sluice, the riffle-box, etc.—were devised and used in this region, and were carried hence to California when, 25 years later, the trained miners of this region emigrated in a body to that newer and richer field. Since that emigration there has been but little placer mining done in North Carolina. Still this sort of mining has never entirely ceased, and in some sections, and by a few families, it has been followed continuously to the present. The richest deposits within reach of water have been worked over, but there are large areas still untouched, because inaccessible to water without considerable outlay for ditching, canalizing and fluming, to which neither the capital nor the enterprise of the region is equal.

### Buhr Millstone.

This valuable mineral has been found at several localities in the State; one examined by the State Mineralogist a number of years ago is a small outlier in Owen's River valley, Inyo county, known as "Little Butte," which is a prominent landmark on the line dividing Russ from Inyo mining districts. It lies partly on section 13, township 13 south, and range 35 east; and partly on section 18, same township, range 36 east. The stone is hard and brecciated, somewhat resembling the celebrated French buhr stone. A sample has been placed in the State Museum. Dr. J. B. Trask, first State Geologist of California, says in his first report that it is found in great abundance on Pit River—now Modoc county—extending to the north of Goose lake. The following quotation shows what importance he attached to the discovery. Its admirable adaptation to milling requires no comment. The value of this rock cannot be too highly esteemed in this State, where the prospective is so flattering of its becoming a grain growing country equaled by few on the Atlantic slope. The heavy expenses that are now incurred, and the future wants of the State in this particular, will be obviated, and our dependent condition on foreign import destroyed. These rocks have as yet attracted little notice, but the rapidly increasing wants of the State will ere long bring them into requisition.

The Sunday law was enforced at Biggs, Butte county, all the business houses being closed.

## DEWEY & CO'S

Scientific Press

Patent Agency.

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

No Drouths! Sure Crops!

READING RANCH,  
Shasta Co., Cal.

Good Land!  
Sure Crops!  
HEALTHY CLIMATE!  
Prices Low. Terms Easy.

TITLE PERFECT.

The Reading Ranch, in the Upper Sacramento Valley, originally embracing over 26,000 acres of choice grain, orchard and pasture land, is now offered for sale at low prices and on favorable terms of payment, in subdivisions to suit purchasers.

The ranch was selected at an early day by Major P. B. Reading, one of the largest pioneer land owners in California. It is situated on the west side of the Sacramento River and extends over 20 miles along its bank.

The average rainfall is about 30 inches per annum, and crops have never been known to fail from drouth.

The climate is generally healthy. The near proximity of high mountain peaks give cool nights during the "heated term" which occurs in our California summers. Pasture, wood and good water are abundant. The hills are mostly level, with complete drainage.

Figs, Grapes, Peaches, Prunes, Almonds, English Walnuts, Apricots, Currants, Berries and other common fruits can be raised with success on most of the tract without irrigation. Also, Alfalfa, Vegetables, Corn and all other cereals ordinarily grown in the State.

The soil throughout the tilled portions of the ranch proves to be of great depth and enduring in its good qualities. It is quite free from foul growths. The virgin soil among the large oak trees on the bottom land is easily broken up and cultivated.

The title is U. S. patent. Prices range principally from \$5 to \$30 per acre.

The California and Oregon railroad traverses nearly the entire length of the tract. There are several sections, stations and switches, besides depots at the towns of Anderson and Reading, all of which are located within the limits of the ranch.

The Sacramento River borders the whole tract on the southeast. Its clear waters are well stocked with fish. Good hunting abounds in the surrounding country.

Producers have a local market, which enhances the value of their produce. The railroad transportation route is level throughout to San Francisco. A portion of the land is auriferous and located near rich mines now being worked. Land suitable for settlers in colonies can be obtained on good terms.

Town lots are offered for sale in Reading, situated on the Sacramento river, at the present terminus of the railroad. It is the converging and distributing point for large, prosperous mining and agricultural districts in Northern California and Southern Oregon. Also, lots in the town of Anderson, situated more centrally on the ranch. Lots in both these towns are offered at a bargain, for the purpose of building up the towns and facilitating settlement of the ranch.

Purchasers are invited to come and see the lands before buying here or elsewhere. Apply on the ranch, to the proprietor.

EDWARD FRISBIE,  
Anderson, Shasta Co., Cal.

Location of Shasta County.

Shasta County lies not far from midway between the two most important ports on the Pacific shore, i. e., San Francisco and Portland, Oregon, and directly on the route from Mexico to British Columbia. The town of Redding, at present, and probably for years to come, the head of railroad transportation on the California side of the mountains intervening below Oregon, is distant from San Francisco by railroad (via Vallecjo) 255 miles; from Sacramento City, 169 miles; from Marysville 117 miles.

Persons thinking of buying or renting land will not likely regret a camping or excursion trip to this upper Sacramento country.

DuBOIS' Automatic Quicksilver Feeder.

A machine for feeding quicksilver to the mortars of GOLD MILLS. It is so connected to the cam shaft, that each revolution of the large ratchet wheel, which can be regulated to revolve once in one, two, three or four minutes, as desired, dips a small cup into a reservoir of quicksilver, and by a mechanical movement, empties the contents into a pipe leading down to the mortar, supplying an exact quantity at regular intervals, superseding ordinary hand-feeding, which is of necessity subject to great irregularity, and liable to neglect. It renders the amalgamation of all the gold in the pulp equally certain and perfect. Price complete, \$100.00. Send for circular.

## Mining Statistics of Counties.

The Mint Bureau of the Treasury Department has authorized the Superintendent of the Mint in San Francisco to collect statistics of the production of the precious metals in the States and Territories of this coast. In accordance with this authority, circulars asking for information will be sent to every incorporated and private mine; to Wells, Fargo & Co.'s agents and to prominent merchants in mining localities for estimates of the production of the Chinese, small producers by arrastras, the pan, etc., by which means it is hoped to receive returns of the entire production.

Circulars are sent from the Mint every six months—Jan. 1st and July 1st—for the reason that the production of the government fiscal year which ends June 30th is six months each of two years.

The productions will be classified as to the manner or mode of production—whether argentiferous, lead ore, vein quartz, drift, placer, or hydraulic, etc. But what will be of most advantage to every county will be the publication for each fiscal year of the production of the precious metals for each county—only, however, in the aggregate or the totals. Individual returns will not be published, and are seen by no one but the Superintendent and his assistant, the statistician in charge, by whom any communication relative to the production of a mine will be safely guarded.

This publication of the yield by counties will be of benefit in attracting the attention of men of means who are each week arriving in San Francisco from all parts of the world, and who are often imbued with the desire to invest in mining property—of which we have so much awaiting the advent of capital—and who will naturally look for statistics of the production of gold and silver, and will in many instances go to those localities known to be productive. They can by this means often be induced to invest, and will thus help develop the main industry which has been the means of making us noted to the world.

It is therefore hoped that every mining company, large or small, and every person receiving a circular of inquiry from the Mint, will promptly and freely make returns of productions, and impart such information as will give each county full credit for all it is entitled to, and by this means assist in aiding the mining industry of our country.

If local papers in mining counties will insert this article, or something similar, to call attention to the matter, it will do much to further the work and assist in bringing to notice more prominently the mines in their own localities.

## Our Railroad Industry.

The completion of so many new railroads in the country is making it busy times for the car builders. One company alone, in Boston, Massachusetts, whose business last year amounted to over \$1,000,000, has double the number of contracts it had then.

The Baldwin Locomotive Works completed 513 new locomotives in 1880, and rebuilt 17 more, making a total of 530 during the year, besides doing a large amount of other work during the same period.

The manufacturers of standard locomotives in the United States have orders enough to keep their works busy during the entire year. The railroad companies cannot get locomotives as fast as their travel and traffic requires, notwithstanding the works are being driven to their utmost.

Mexico is entering upon a new class of revolutions, and is undergoing a wonderful transformation at the hands of American enterprise and capital. It is estimated that in the incredibly short space of seven months \$68,000,000 has been invested in railways and mining enterprises from the United States.

About the first of March four trial locomotives were shipped from the Baldwin Locomotive Works to the Mexican National Railway, a bid to supply the road with 200 engines having been tendered some time before. A contract for the proposed 200 has since been signed and the work of construction has been begun.

## The Pacific Copper Smelter.

No class of mines in the great and practically unlimited mineral zone of this western continent are now attracting so much attention as those of copper and argentiferous galena. The mechanical appliances for the treatment of these ores have been so much improved of late as to greatly cheapen the cost of production, largely enhance the value of all such properties, and make available a great number of mines carrying a

interruption, and a continuous use of many years with but little cost for repairs. Among other obvious advantages claimed for this style of smelting furnace is that, as shipped, it is complete and ready to set up—no brick or stone work being required in its construction. This saves great expense and loss of time, as most places where such works are put up are destitute of any material or facilities for mason work. No tuyeres are exposed to the fire, and the distribution of the blast is such as to avoid dead centers, prevent any tendency to freezing and

smelter. We venture the statement that it would be hard to find a copper mine in all the mineral range of the country that would not go higher than this, while it is a well-known fact that there are in Arizona, New Mexico, Colorado and Nevada vast deposits of copper ore that will average from 8% to 12%, and a large number of mines that will give twice as large a percentage. It will thus be seen that with such approved appliances for reduction no field of mining venture offers more promising returns.

The Pacific Iron Works are making smelters on this plan adapted to argentiferous galena ores, and have a large number working with results equally satisfactory. The firm have long made a specialty of this class of machinery and have worked out the details of their furnace plants with a care which shows the closest study and observation as to the requirements of this class of work. Their success in handling these ores has undoubtedly greatly stimulated exploration and development in this class of mines—the products of which are already attracting much attention in the principal metal markets of the world.

## Industrial Progress.

The United States Treasury reports for the last few years are deeply interesting. For the year ending April 30, 1881, our exports, dealing in round numbers only, amounted to \$912,590,000; while our imports for the same time were only \$654,550,000, showing a balance in our favor of \$258,040,000, against an excess of only \$178,460 during the previous year. The excess of coin and bullion received for year ending April 30, 1881, is \$92,680,000, against \$76,296,000 for the previous year. It is thought that the excess of exports during the present fiscal year will exceed those of last year by fully \$50,000,000. The amount of precious metals held in this country now is greater than any other country on the globe except France.

Under the protective system we have learned to manufacture a great number of articles formerly imported, while in many articles we are now able to ship abroad and compete with the most advanced nations of Europe. The first manufactory of translucent porcelain in the United States has recently been established at New Orleans. We have but just started in the plate-glass business; but we already number six factories, with 134 pots. The home manufacture is rapidly growing in favor, and will soon drive the foreign article out of the market. Indeed, this trade is everywhere just now in a transition state, which must, sooner or later, end in the "survival of the fittest." In this contest American manufactures will not be found at the bottom.

The watch trade of the country now amounts to about 3,000 watches a day, of which number our seven leading factories furnish about 600. There are quite a number of smaller factories, from which we have no reports. The importation of watches is constantly falling off; while many of our home-made find a market in India, South America, etc., in competition with European makers. Our mechanics have effected a revolution in this business by the introduction of new and superior machinery.

Our iron industries were never more prosperous than now. Our steel rolling mills have orders for all the rails they can manufacture for several months to come. We are also making decided progress in iron ship building. At a recent meeting of business men of Bath, Me., \$100,000 was pledged for an iron ship-yard, and a committee was appointed to raise \$200,000 more by subscription. Over 1,000 printing presses have been shipped from Philadelphia to France since the Centennial.

A paper manufacturing firm in Pennsylvania has purchased 20,000 acres of timber land, the timber upon which they propose to convert into paper pulp.

About two years ago pine straw, or leaves, became an article of trade in the Wilmington, N. C., market, and now it is impossible to supply the demand. Shipped North it undergoes certain preparations, and is then used for stuffing mattresses and for other purposes.

THE PACIFIC COPPER SMELTER.

lower grade of ore, that could not heretofore be worked with profit. The smelting furnace shown on this page represents an improved style of water jacket copper smelter, built by Messrs. Rankin, Brayton & Co., of the Pacific Iron Works in this city. It embraces many features that are entirely new and of great practical utility. From evidence at hand we are satisfied that no other furnace can compare with this in economy of working and capacity for continuous and uninterrupted work.

All practical smelters know that the loss of time in shutting down for repairs required for most furnaces is the great drawback to effective and economical work. It is claimed that with ordinary care from six to 12 months' runs can be made with this furnace with little or no

secure perfect combustion, thus insuring the greatest possible economy of fuel. The arrangements for drawing off the slag are such as to secure a clean and high grade of bullion.

Large numbers of these furnaces are working in all parts of the coast with the most satisfactory results. The most notable success in this way, perhaps, has been the Copper Queen works, at Bisbee, Arizona. This company, with one of these 30-ton smelters, has turned out in six months, 1,200 tons of bullion, averaging 97% fine, and developed a property only second in value to the famous Calumet and Hecla.

Under favorable conditions as to fuel and water, ore averaging not more than 4% to 5%, it is said, can be worked with profit by this

### Fresno County Mines.

#### A Description of the District and the Mines.

EDITORS PRESS:—Perhaps no part of California is less known to the outside world as a mining section, in comparison to the amount of gold produced, than Fresno county. It is a fact that comparatively few mining sections gain more than a temporary reputation with nothing but placer mines, upon which that reputation is founded. Placer mines, though often very rich, rarely create more than a temporary excitement, and Fresno county is little known to mining men, for the reason that it is only within a very few years that quartz mines, the only really solid basis upon which a permanent reputation can be laid, outside of a few gravel mining sections, have been prospected and worked. Fresno county, although contributing her portion of dust from nearly every gulch and ravine in the Sierra, from the palmy days of '49, when "ounce diggings" were often left for something better, down to the present, when the Mongolian rocks out four hits to one dollar "paw," and sometimes more, per day, has been no exception to this rule.

It has been only two or three years since that quartz mining was placed upon a paying basis, and of course, no very extensive development of mining properties has been made. In mentioning the mining properties Potter's Ridge district, Fresno county, I shall endeavor to speak of those only which have paid dividends, where reduction works are in operation, or which promise to be paying mines as soon as reduction works are erected.

#### The Most Noted Mine

Of the district, and about the only one which has more than a local reputation as a dividend paying property is the Fresno Enterprise mine, which is situated on the northeast slope of Potter's ridge, a spur of the Sierra Nevada mountains, from which the district takes its name, 5 miles from Fresno Flats, and 50 miles from Madera and Berenda. The course of the vein is nearly northwest and southeast, dipping to the southwest near the surface, and at a depth of 150 ft. assuming a nearly vertical position with a slight dip to the northeast. The formation is slate. The highest outcroppings of the vein are near the "Point of Discovery," some 1300 ft. above the Fresno river which flows by the base of the ridge. Since the present owners have had the mine, only two years, the following developments have been made: Four tunnel levels, two incline shafts, many winzes, crosscuts and intermediate levels have been driven, which, if in one continuous line, would make a tunnel more than one mile in length. The north tunnel level commences 200 ft. from the northern boundary line and follows southeasterly along the vein a distance of 510 ft.

The upper tunnel level commences 500 ft. from the southern boundary line, and follows the vein a distance of 150 ft., showing a vein one to two ft. thick for the entire distance, rich in free gold. The prospecting tunnel is 150 ft. north of the southern boundary, and follows the vein in a south-easterly direction for 100 ft. This level also opens a chimney of high grade ore. The tunnel level is near the center of the location, and is about 400 ft. in length. Three hundred ft. from the mouth of this level, a crosscut is being pushed to intersect the shaft sunk from the upper tunnel level. It is 125 ft. in length, and the work is progressing. About 200 ft. southeast from the mouth of the north tunnel, is the Baker incline shaft, which is connected with the north tunnel level at a depth of 100 ft.

An intermediate level was run from this shaft at a depth of 40 ft.; the southeast branch following the vein a distance of 200 ft., and the northwest branch extending to the surface, a distance of 80 ft. The former branch of this intermediate level is connected with the north tunnel level by several winzes, and two up-raises have been pushed from the north tunnel, from north of the Baker incline shaft. From the north tunnel level two shafts have been sunk to, and below the water level. Forty-six feet from this level an intermediate level extends along the vein a distance of 350 ft., connecting the two shafts. It is from this level that the richest rock is being taken out and crushed now. The last crushing of which averaged \$163 per ton.

Another incline shaft, situated near the center of the claim, intersects the upper tunnel level, then follows down the vein a distance of 108 ft. Tunnel level No. 2, at a point below the Baker shaft, will cut the vein at a depth of 120 ft. below the north tunnel level. This tunnel is in 120 ft., and the work is being pushed to completion. Although it takes the reader only a few moments to scan this account of these developments, I can assure him that it took me very much longer to see them.

Messrs. Haley, Fairbanks, Meyers and Sheehy are the principal shareholders of the stock of the company. Under the supervision of Mr. John Haley as Manager and Dr. M. J. Goodfellow as Superintendent, the sum of \$200,000 has been taken out of the mine in two years,

which, considering the primitive method of reducing the ore, is, to say the least, encouraging. Of this \$200,000, \$125,000 have been paid to the stockholders in dividends, and the remainder has gone for expenses and development of the mine. The reduction works consist of three arastras.

Until a year ago only one arastra was in operation. About a year ago the second arastra was built, and in May the third arastra was completed. Since then the three arastras have been grinding. The crushing capacity is about 100 tons per month. The arastras are run by water power and go day and night. The last rock crushed averaged \$163 per ton, but of course the rock was assorted. The gold is very fine and returns from \$20 to \$20.20 per ounce.

Leaving the enterprise, we cross the Fresno and follow down the river over a rough mountain trail till we reach Indian peak, which we cross and arrive at the place which bears the now euphonious but suggestive name of Grub Gulch.

In this gulch and on the ridges which rise above it, several promising prospects have been found. The mines of this section are recent discoveries, and instead of calling them mines I shall call them prospects. I think the word mine ought to be reserved for those properties which having been fully tasted are found permanent and good.

#### The Best Developed Prospect

In this vicinity is the Surprise, owned by John Gilman, and at present bonded to Sunderland & McDonald for \$6,000. Several shafts have been sunk on the vein, the deepest being 120 ft. The vein is near the gulch, and at this depth the water causes much inconvenience to the prospectors. The formation is slate. The vein is seven feet thick, with no waste in the vein matter, and has well defined hanging and foot walls.

#### Other Mines.

Near the Surprise is the Gambetta, owned by Dr. M. J. Goodfellow, Superintendent of the Enterprise, which is a very flattering prospect. The formation is the same as the Surprise, but the vein is much smaller. Some very rich rock has been taken from the mine. Mr. D. Walsh, a mining Superintendent of 20 years' experience is superintending the prospecting of the property.

The Hancock, owned by Anderson & Bronson; the Defiance, owned by Bronson & Melon; and the Red Rover and its extension, the Antelope, a recent discovery, are all good prospects. The Antelope is owned by Biegle & Peterson, and the extension by Messrs. Hale, Slumlick & Zoeller. The vein is from two and a half to three ft. in thickness.

In my next I shall mention the mines of Coarse Gold Gulch and vicinity.

SAMUEL L. HOGUE.

Fresno Flat, Cal., May 26th, 1881.

### Amador County Mines.

EDITORS PRESS:—I have just returned from a tramp among our quartz mines, and it occurred to me a few items of interest would no doubt be appreciated by the readers of your very valuable paper. I presume you are well aware of the legal troubles existing between the Empire and Pacific mines at Plymouth. I found on my arrival at the mines the 40 stamp pounding away on a fair grade of ore from the Empire; the other 40 idle since the contract has expired with the Pacific Co. for crushing the ore from the latter mine. Since my last visit I find a change in the management of the Empire. It seems to me there was a sufficient force of officials before the change took place. At present I find one superintendent, one assistant, one foreman, one or more shift bosses; and what need for the addition, I fail to see. In previous administrations they had one superintendent and one foreman, which is quite sufficient, particularly when a mine does not produce sufficient to pay dividends. Well, that is not any of my business; it is the stockholders, and not I, who pay for the music.

I simply speak of this from observation. As to the proper handling of such extensive properties with economy, I consider that a mine of the character of the Empire, with such a vast amount of low grade ore, has to be worked with skill, and at the very lowest cost, in order to produce sufficient to pay its own way, let alone dividends.

The mine has its own water power, with a ditch large enough to float all the timber used in and about the mine, a 60-ft. head at mill with a double turbine wheel as a driving power for the 80 stamps. The Pacific mine has the finest and most complete hoisting works in the county.

The mine is in charge of Bill Jones, as foreman, formerly of the Empire, who gives entire satisfaction to his employers. Are making good progress in sinking their three-compartment shaft and expect to tap the ore body in 90 days. They have now an abundance, of good quality, and are preparing for a 40-stamp mill, to be erected within 90 days, with all modern improvements, to be driven by a burdy gurdy wheel—the water to be brought from the Amador canal, at Sutter creek. About 100 men are at present engaged in bringing the ditch to Plymouth, a distance of about 13 miles, four of which will be pipe.

I will give further particulars of the Pacific mine and mill improvements in a future letter,

In going south I find a few prospecting mines, such as the Hercules, on Dry creek, idle at present, but I understand have a good prospect for a paying mine. Lack of funds compelled the suspension for a time only. Potosi, under a new management, is about to start, with great hopes for the future. Maryland, farther south, is still prospecting, with a very long purse in England to draw from. Seaton, with one man in possession, is awaiting a U. S. patent, and, it is probable, some \$20 pieces to prospect this mine with. North Gover is idle and likely to continue in that condition for some time. The Gover mine will most likely start with renewed life in a short time; this mine is a good piece of property if properly handled. I am on my way to the Bunker Hill mine, and I shall report further in due time.

QUARTZ MINER.

Sutter Creek, June 6, 1881.

### Mount Baldy District, Utah.\*

[From our Traveling Correspondent.]

On Ten-Mile creek, near Marysville, Pinta county, Utah, are situated the Melakoff, Clara, Legion of Honor and Fairview mines, belonging to the Marysville G. & S. M. Co., of which J. M. Benedict is president, and Gen. C. H. M. y Agramonte, vice-president and superintendent. The Melakoff and Clara commence at the bed of the creek, running south. The tunnel on the former is 30 ft. above the bed of the creek and has been run 130 ft. on the vein, showing a fine body of mineral the entire distance. The average width of this ledge is about 11 ft., gold and silver-bearing quartz, which assays from \$15 to \$460. The assays shown me had all been made by Mr. F. M. Bishop, of Salt Lake City, who stands at the head of his profession in Utah. One hundred and eighty feet above the creek a prospect tunnel has been driven, showing the same class of mineral throughout, and 300 ft. still higher up, the company has commenced to strip the vein its entire length of 1,500 ft.

On the other claims considerable prospect work has been done, showing a rich body of mineral. There is an abundant supply of water, and wood enough to last for years. The company have about 400 tons of ore on hand.

General Agramonte is now erecting a Steen's Reliance ore battery, with a capacity of 12 tons per day, and a couple of Paul's Americanized arastras. The former is claimed to be the simplest ore crushing machine ever made which would do the same amount of work, and less liable to get out of order than the common cam mill. Each of these batteries, it is said, will crush as much ore to a given fineness as eight common stamps of same diameter of bead, and save 30 to 40% of the power, as the friction is very much less for each stroke, and each stroke is much more effective. The wear of came and tappets is also avoided, and no trouble about their getting loose, as there are none.

The improved arastra, which they are erecting, is an invention by which pulverizing, amalgamating and settling are done in one machine, thus saving the expense of several separate ones; so that with suitable crushing machinery, it will make, not only a cheap, but the most perfect and consequently profitable quartz mill.

North of these mines is the Mt. Baldy mining company's property, of which Gov. E. H. Murray is President. The Uncle Sam is their principal claim. The tunnel has been run about 75 ft. on the vein, showing rich ore all the way. Some assays have shown as high as \$350 in gold and silver. From this tunnel a shaft has been sunk to a depth of 110 ft., all the way in ore; so that the Uncle Sam promises to be one of the best mines in the vale.

Adjoining the Mt. Baldy group is the Rothschild mine, owned by D. C. Tate and Louis Leifer. The whole of the ground has been thoroughly prospected by tunnel and shaft; on the north side of the claim is a 150-ft. tunnel, showing very rich silver ore; on the south side is an incline shaft 40-ft. deep. This mine is being very handsomely worked, both Mr. Tate and Mr. Leifer being old and experienced miners.

Three miles south of Marysville, on Cottonwood creek, in the same district, is the Deer Trail mine, which has been more developed than any other mine in this vicinity. It shows a large body of low grade ore, running from 25 to 50 ounces in gold and silver, and a rich strike was recently made on this property. Above the Deer Trail is the Pluto, owned by Campbell & McNorton. It is very rich, principally in gold, but has been gophered out by men who only work it when they take a notion to do so. The Crystal is an immense deposit of smelting ore, averaging over \$100 per ton, and is owned by G. M. Scott and H. D. Converse. Haynes & Sheldon own the Clyde, and are now running a tunnel to tap the vein, which they expect to do at 800 feet. It has excellent surface indications for smelting and milling ores. The extension of the Clyde, owned by Ira Pfoutz and Richard Young, is very rich, and has over 200 feet of workings. They have plenty of ore on the dump, and some of their assays have run as high as \$600.

#### Ohio District.

The Ohio district at Marysville adjoins the Mt. Baldy district. The principal mine now being worked is the Fillmore, owned by C. B. Robertson, Recorder of the district. It is developed by a tunnel and a shaft, which is now down over 130 ft. Both are in milling and

smelting ores averaging 50 to 70 ounces silver.

The Copper Belt is a very fine mine, containing copper, sulphide of silver and hromide. Ore assaying as high as \$1,100 has been shipped for the last two years. This and the Sierra Nevada, situated on the other side of an almost inaccessible canyon, are owned by Hugh McCorkindale & Co.

A company, known as the Occidental M. Co., has just been formed by D. C. Tate, W. D. Wilson, and others, to work a newly discovered group of mines in this district.

The Bully Boy and Webster are owned by Haggin and Tevis, and it is reported that they will resume work on them this season.

The other leading mines of the district are the Beecher and Ferris, owned by John and Al. Ferris; the Sonoma, owned by Captain Timoney, and the Mountain Jaguar, belonging to General Agramonte. All are in granite or porphyry formation, and the ores are more or less refractory. A. L. M.

\* This report has been delayed some weeks owing to the accident which befell our correspondent since leaving Utah.

### Volatilization of Gold.

EDITORS PRESS:—In your issue of May 7th last, I note an article with the above caption, which appears to be taken from Mr. Aaron's late publication. I am backward to attempt to controvert the distinguished author, but it appears to me that the statements contained therein are of so extraordinary a character, and so opposed to the notions of chemical writers, that a great deal of criticism is sure to be evolved. The gentleman's investigations, as recounted by himself, were very ingenious in their way, but let me ask, why did he leave off with the accumulation of so few facts? If, indeed, gold is volatilized in this unaccountable manner, so contrary to previous experience, why not let us into the secret of the "peculiarities" that he hints at in regard to the concentrations? I would like to know how he knew that "the material could be roasted with little or no loss, if no salt were used, because some assays had been made in that way." This seems to me quite inconclusive; because loss could have occurred in assaying such a very remarkable substance as well as in roasting it. Then the roasting of two ½-ounce samples, one with, the other without salt, while it may afford grounds for a suspicion, is not a tithe of the evidence necessary to establish a hypothesis, far less is it sufficient base for a section in a work that could and should be made authority on metallurgical matters.

Some of that yellow fluffy sublimate, if it existed at all, would, if subjected to chemical examination, prove the existence of a hitherto unsuspected compound of gold. Let us hope some of it was saved.

It is a curious fact connected with the subject, that no one has previously discovered the demoralizing effect of salt in gold assaying. I mention this, as it is apparent that if it is so very injurious to the temperature of the reverberatory furnace, we might expect still more marked effect when it exists in equal quantities with the ore, and is enclosed with it in a crucible at a higher temperature.

Possibly, although it does not appear from the text, the author only wished his remarks to apply to that particular lot of concentrations. In that case, the article would be more appropriate to a journal of chemistry than a text-book on leaching gold and silver. At all events, that "metallurgist in reduced circumstances" should have been set to work to find out the peculiarities of the material. HERBERT LANG.

Sonsbyville, June 5th.

### Mines at Plymouth.

EDITORS PRESS:—Plymouth, Amador county, keeps on improving and is to be one of the largest mining towns in Amador county. The Empire shaft is down 1,280 ft. in depth, and the Pacific is nearly 800 ft. Charles Green commenced with 50 men Monday to dig a ditch for laying pipe to bring water from the Amador canal. It will take about two months to complete the work, then Plymouth will have clear water, with plenty of it and about 300 ft. pressure.

The Empire mine has an 80-stamp mill and the Pacific will soon commence to build a large mill. The Pacific is a new shaft south of the Empire which they commenced to sink about ten months ago, and is now 800 ft. They will put the shaft down about 1,000 ft. before they commence to run levels. The Pacific mine has been prospected from the Empire shaft at a depth of 1,200 ft., and the vein is 60 ft. wide and contains ore that will pay \$15 per ton. Mr. Harvey, from Amador, is building a new hotel, and intends to have it completed by the 4th of July.

Plymouth is to have a Fourth of July celebration, and from the names on the programme, of the gentlemen of Amador county, that have the management of it, I am satisfied they cannot fail to have a good one. PROSPECTOR.

DIFFERENCE OF TEMPERATURE BETWEEN THE POSITIVE AND NEGATIVE CARBON.—Rosetti has found that the temperature of the positive carbon of the electric arc is between 2,400° and 3,900° centigrade, and that of the negative carbon between 2,500° and 3,900°, making, therefore, the temperatures of the extreme points of the electrodes not below 2,500° and 3,900°.

# MECHANICAL PROGRESS.

## Mode of Construction and Operation of the Electric Railway.

The electric railway recently opened with much ceremony in Berlin, is constructed upon the principle devised by Dr. Siemens, of London, England. It is a narrow gauge, three-rail street railway, located on the outskirts of the city, and about two miles in length. The cars carry 14 passengers each. The electricity is generated by a dynamo-electric machine, driven by a 60-horse power engine. A miniature circular railway track, constructed upon the same principle with that at Berlin is in operation at Sydenham, England. The electric locomotive has a length of about four ft., with a breadth of three ft., and is three ft. in height, weighing three-quarters of a ton. It is, in fact, a Siemens dynamo-electric machine, neatly boxed in and mounted on a truck with four metal wheels, and provided with a brake and alarm bell for its control by the man in charge. A stationary engine of about eight horse-power nominal, in a shed about 30 yards from the railway line, drives a stationary dynamo-electric machine, from which the electric motive current is primarily obtained. Two wires are connected with this fixed dynamo machine.

By one of them the current flowing out is conveyed to the mid-rail of the railway, to which it is attached by an iron plate bolted on. The second or return wire is attached to the exterior rail of the railway. The mid-rail is supported upon wood blocks and is thus in a certain degree insulated. Beneath the electrical locomotive a brush of iron wires sweeps the mid-rail, and the electrical current is thus taken up into the locomotive, where it passes through the mounted Siemens machine within it, the large bobbin of which is thereby caused to revolve, and the current passing away by the wheels of the truck to the exterior rail of the road, is conveyed back to the stationary dynamo-machine. As the current thus circulates, and the bobbin of the mounted machine revolves, it drives the four wheels of the truck as the locomotive moves on, hauling after it a load of nearly three tons with ease. The electrical locomotive is easily managed; by applying the brake the current is cut off as a driving-power, whilst the wheels are at the same time mechanically skidded.

By reversing the current the locomotive can be driven in either direction as desired. The circulation of the electro-motive current from the stationary dynamo-machine to the mid-rail, and from the mid-rail to the locomotive, from it again to the outside rail, and from it back to the fixed machine, depends entirely upon the superior conductivity of the metallic wires and rails over the conductivity of the earth; and this mode of driving the electrical locomotive seems to make such a system open to difficulties upon railroad lines of any considerable length.

The latest accounts from the Berlin railway report many difficulties in the way of its successful operation. It was found that the electricity escaped, in great quantities from the middle rail, in spite of the best insulation which could be devised. This loss will be still greater in the wet, and mud, and snow of winter. It has accordingly been determined to conduct the current by a copper wire properly insulated and attached to pillars erected by the side of the track. The current will be conducted from the copper wire to the locomotive by means of contact rollers.

The telegraph, within a few days, has described another trouble met with at Berlin, as follows: "A horse while crossing the electric railway, having set his hoof upon the rail, was instantly thrown down, and another horse, having also touched the rail with his iron-shod hoof, received a shock which sent him galloping off in wild terror." *L'Electricite* affirms that electric railways can be successfully employed only in tunnels or on elevated roads.

**DURABILITY OF BUILDING MATERIALS UNDER HEAT.**—Dr. Hiram A. Cutting, of Vermont, has made a series of examinations into the durability under heat of different kinds of granite, sandstone, limestone, marble, conglomerate, slate, soapstone and artificial stone. Granite began to yield at a temperature of between 700° and 800°; it became cracked between 800° and 900°; generally cracked between 800° and 950°; and was made worthless by or before reaching a temperature of 1,000°. Sandstones showed a greater power of endurance, massive limestones still greater, and marble the greatest, while conglomerates seem to have been among the weakest stones. The least absorbent and the most absorbent of the granites were equally the granites most destructible by heat.

**SETTING CAR WHEELS.**—Car wheels are now kept in their place without being keyed on. In former times they were almost sure to precipitate an accident; besides, keys would drop out by the constant jar and be weakened by the axles and wheel. Axles are turned to fit the wheel snugly and are driven in place by hydraulic pressure. Previous to being driven, the axles are covered with a thin coat of white lead and oil, which hardens in a short time and holds the wheel so firmly in place that a pressure of from 100 to 140 tons is required to remove a broken axle from the wheel in which it is placed.

# Pressure, Instead of Hammering, for Shaping Iron.

The following article on the advantage of treating iron as a plastic material—employing pressure, rather than the hammer—we clip from *Lefail's Mechanical News*:

The original method of forging iron by the simple application of the hammer, continued and varied, until the desired form was given to the product, was largely improved upon by the introduction of drop-forging. By the use of a die or matrix, and the weight and gravitation of the powerful hammer falling upon the iron, it was made to assume almost instantly the shape required, under the immense force thus brought to bear; and for a great number of processes this method has been found entirely satisfactory. Not only was the rate of production vastly increased by this advance of the art, but the quality of the manufactured article, as to the condition of the fiber of the metal, where there is not too radical a change from the original form of the bar, has proved to be all that its practical use and service require.

In the exceptional cases just hinted at, however, it was perceived that a still finer adjustment of cause and effect was demanded to meet the necessities of the case. If the change of form is such that the percussion of the hammer in drop-forging destroys the fiber of the iron, the result is a failure so far as the quality of tenacity is concerned. How to meet this difficulty, and apply the necessary amount of force without the destructive effect of the sudden stroke, has been a perplexing question. To administer the blow, and yet preserve the continuity of the fiber was an evidently impossible fact. How, then, should the requisite degree of power be employed upon the iron so as to give it the form of the mold, yet without disintegrating the metal itself?

The solution of this problem has been found in treating the iron as a plastic substance, which it in fact becomes when heated to a certain degree—something less than a welding heat, and very far below a fused condition, but still imparting to it sufficient mobility to serve the purpose. In this state it is subjected to enormous pressure, steadily yet rapidly acting, and forcing it into the matrix with irresistible effect, inasmuch that when the product of this compressive forging is examined, it is found to be not only perfect in shape but unbroken in fiber, and therefore having all the toughness which it possessed in the bar. The work is done with speed, and thus far there is no dissent from the verdict of approval with which the results have been received by the iron working community. The new process is perhaps not strictly a discovery; it appears to be rather the fruit of a closer knowledge of the metal with which it deals, and a more accurate determination of the precise state in which it will submit to be treated as a fluid, while still retaining its texture as a solid substance. "Getting it down to a line point" is a phrase from the vocabulary of the street; but it gives in few words the exact nature of this latest achievement in the art of iron working, and indeed of most of the substantial victories which science is daily winning for mankind.

**EFFECT OF IMPURITIES ON COPPER.**—In a paper on copper smelting, Mr. Henry Hussey Vivian, a member of the well-known firm of Swansea smelters, states that he had been able by synthetic trials to determine the effect of impurities upon the quality of copper. He had found that 1000th part of antimony converts first-rate best selected copper into the worst conceivable, so bad as to be only fit for brass, and that one 4000th part makes it unfit for anything but inferior brass purposes and below the quality known as tough ingot. He discovered that one 8000th part reduces it from "best selected" to "tough ingot" quality, and that one 16,000th part sensibly deteriorates the copper. He stated that 1000th part of nickel, cobalt, bismuth, arsenic or phosphorus reduces "best selected" to "tough ingot," while nickel and arsenic in combination and mixed in the proportion of one 500th, make copper unfit for brass, thus showing that two substances in combination may produce a far more hurtful effect than either of them separately.

**PULVERIZED FUEL.**—The experiments of the Alexander Steamship company in burning pulverized coal, or culm, continue to be very satisfactory, and are regarded as promising entire success. They will persevere until they feel warranted in introducing the process on board their steamers. The experiments, as we are informed, are directed chiefly to two points; one relates to the construction and position of the retort or lining of the furnace; the other, to the force of the blast used in atomizing the coal. When the latter is rightly graduated, there are neither ashes nor smoke. If it is not strong enough, a part of the coal dust falls unconsumed.

**EXPERIMENTS WITH STEEL WIRE.**—Herr Strouhal and Barns report in *Wied. Ann.* certain experiments in which steel wire was treated so as to show all degrees of hardness between the glass hard and annealed states, and it was shown that the thermo-electric and galvanic properties of steel vary with the degree of hardness in a very sensitive manner. Their researches are said to throw some useful light on the nature of the annealing process and on the magnetic behavior of steel in relation to its hardness and other properties.

# SCIENTIFIC PROGRESS.

## Polarization of Sound.

Prof. S. W. Robinson has an article in the *Journal* of the Franklin Institute, the object of which is to show, by theory and experiment, that longitudinal vibrations, such as sound waves, can be polarized; and not only this, but also to show that it is irrational and improbable for vibrations in extended media generally to be primarily otherwise than longitudinal. All this is aimed especially at the "transversal theory" of light.

The phenomena of radiation, refraction, diffraction, diffusion, interference and polarization are, with the exception of the latter, common to light and sound, and it is for the sake of explaining polarization in light that physicists have set up the theory of transversal vibration. It is, therefore, only necessary to polarize the sound to place all the known effects of luminous waves in common with sound waves, or to make the theory of longitudinal vibrations universal. The author, after much study, became convinced about eight years ago that undulations generally could be polarized, and after some preliminary experimentation, apparatus was devised by him last May, by means of which he obtained results which verified all his preconceived notions in the matter. The means adopted for polarizing the undulations was the same as that for polarizing light by reflection, but the apparatus can scarcely be described without the use of figures.

The results obtained by Prof. Robinson establish the following facts for sound waves or for undulations: (1) A decided reflection occurs at a surface separating two gases of different density, confirming the views of Henry and Tyndall in this regard. (2) In repeated reflection from such surfaces, the intensity of the final component varies with the relative position of those surfaces, the same following the laws of polarization in light, from which we conclude that longitudinal undulations can be polarized.

With sound polarized, we complete the list of effects for longitudinal undulations which are known to light, viz: radiation, shadow, reflection, refraction, diffusion, diffraction, interference, and polarization; and the laws are common for like conditions.

The conclusions to which the author has been led are summed up as follows: (1) Vibrations in extended media, produced from the action of a remote single center of disturbances, can only be longitudinal, even in light. (2) Vibrations will be to a certain extent transversal when due to two or more centers of disturbance not in the same line, as when two or more independent co-existent systems of undulations combine into one, or when a simple system is modified by such lateral disturbances as a reflection or a refraction. (3) Undulations, to be in a condition called polarized, must consist of vibrations which are transversal, and no necessity exists for assuming vibrations transversal in front of a polarizer.—*Scientific American*.

**WORKING AND MOLDING IRIIDIUM.**—We have already in these columns alluded to the recent discovery by Mr. Holland, of Cincinnati, of a mode for the ready working of iridium by the addition of phosphorus, which is subsequently removed from the metal as described below. Recently, Prof. W. L. Dudley, of the same city, has alluded to the discovery in a lecture, in which he remarked:—"After the metal is brought to a high heat and phosphorus added to it, it is cast into any desired form, and the phosphorus is removed finally by heating the metal in a chalk bath. It is like steel in appearance, but is nearly as hard as the ruby. Acids cannot injure it nor can rust consume it. As the negative carbon in the electric arc, it was used for 60 hours without any loss in weight or change in form. This metal is so refractory that it cannot be hammered into shape when hot, and it resists the file. When, in the way above stated, it is molded into the form, as near as may be, of the article required, it is ground or cut to the finished state by copper disks revolving at a high velocity, on which emery and water are poured."

**A STENOGRAPHIC PIANO.**—A French inventor has exhibited in the French Chamber of Deputies, and to the Municipal Council of Paris, this latest device in stenography. The system consists of a combination of signs through which every sound is represented. The reproduction is as rapid as speaking, and the operator can continue the work for hours. The signs used in the system are printed by machinery, the reading is immediate, and it is even claimed that no knowledge of the language reported is necessary for the operator. The official stenographers propose to acquire the new method if it proves as successful as it now promises.

**IMPERMEABLE PAPER.**—By plunging a sheet of paper into an ammoniacal solution of copper for an instant, then passing it between the cylinders and drying it, it is rendered entirely impermeable to water, and may even be boiled without disintegrating. Two, three, or any number of sheets rolled together become permanently adherent, and form a material having the strength of wood. By the interposition of cloth or any kind of fiber between the layers, the strength is greatly increased.

**THE CAUSE OF THE TIMBER LINE ON HIGH MOUNTAINS.**—This subject is the matter of study by Thomas Meehan. He reports that on Gray's peak the coniferous trees near the line of 11,000 ft., are 30 to 40 ft. high, but at this line they cease as suddenly as if a wood had been cut half away by a woodman's ax. Beyond the timber line the same species exist as dwarf, stunted, trailing shrubs, often extending 1,500 ft. higher up the mountain side. He declares that these stunted plants appear never to produce seed. From his observations in the White mountains and in the mountains of North Carolina, Mr. Meehan concludes that the stunted plants are the struggling offspring of trees which, at no very remote period, extended much farther up the mountain than they now do. The disintegration of the rocks and the washing down of the earth from the higher altitudes, he regards as the prime cause of the disappearance of the large trees.

**EFFECT OF PRESSURE IN CARBONIZING WOOD.** Herr Goppert has lately exhibited a piece of pine which has been submitted for two years to a pressure of 12½ tons in a Silesian mine. It had been compressed to one-fourth, and had been converted into a half-carbonized state through the action of pressure alone, as little moisture had access, and the temperature was never above that of the surrounding atmosphere. It had quite the appearance of a dark-brown colored bituminous wood of the tertiary brown coal formation, but it was without the smell observed in burning bituminous wood. The change of volume was at the cost of the water content of the wood. A considerable amount of oxygen and hydrogen had come off as water, and the composition approximated to that of peat of the older peat formations.

**ACTINIC ZINC.**—Dr. Phipson describes a zinc-white of a dazzling purity obtained by precipitating a solution of zinc sulphate by means of barium sulphide, submitting the precipitate to strong pressure and igniting it with limited access of air. If any barium sulphide escapes oxidation, the white compound, on exposure to the sun, begins to darken, and in about 20 minutes becomes of a deep elate color. If removed into a dark place, it gradually loses color, and in about five or six hours it becomes again snow white. This experiment may be repeated with the same specimen as often as desired. Further, this change of color does not take place under a slip of common glass, whether thick or thin; at most, the compound takes a slight yellowish brown color on exposure to the sun for two hours. The sample on analysis was not found to contain silver or any other substance known as actinic.

**AN ELECTRIC TRICYCLE.**—A tricycle driven by electricity appeared lately in one of the streets of Paris. M. Trouve writes of it to *La Nature*, stating that the tricycle was of English make and very heavy (55 kilogr.), and that he had adapted it to two of his small electric motors, fed by three of the secondary elements or accumulators of electricity, which serve for his polscope. The vehicle, mounted by a friend of his, ran several times along the Rue de Valenciennes, as fast, at least, as a good, ordinary cab. The total weight of the vehicle, with its rider, was about 160 kilograms, and the effective force produced by the two motors was 7 kilogrammeters. The experiment lasted an hour and a half. In view of the results, M. Trouve has set about the construction of a motor which will produce as much as the two others, so as to obtain a greater velocity, say 20 to 30 kilometers an hour.

**DISTILLING ALCOHOL BY ICE.**—M. Raoul Pictet, of Geneva, so well known for his discoveries relating to the liquefaction of gases, announces the discovery of a method of distilling alcohol by ice. Two kilograms of ice are needed for the production of a liter of alcohol; that is, for the distillation of 110 gallons of alcohol, a little less than a ton of ice will be required. The cost of production will include only coal for working the steam engine which drives the air-pump, and the sulphuric acid, the evaporation of which produces the ice. M. Pictet declares that this will notably diminish the expense of distillation, and suggests that the excise on alcohol should be proportionally increased.

**THE UNCERTAIN CHARACTER OF OZONE.**—In a brief review of a paper on the sanitology of odors, delivered in New York a short time ago, by Dr. J. S. Linsley, the *Scientific American* wisely remarks that, in view of the uncertainties touching the occurrence and action of ozone in the air, it may be prudent to wait awhile before admitting ozone to be quite so powerful a factor of individual or national genius, health or social development as Dr. Linsley and others would have us believe.

**LENGTH OF JUPITER'S DAY.**—The Emperor of Brazil has shown the personal interest he takes in science by a note which he has recently transmitted to the French Academy upon the time of Jupiter's rotation. The sharpness of outline and the bright color of the brown spot which has been so long visible, has enabled a Brazilian astronomer, Mr. Crall, to deduce from nearly 1,100 rotations a period of 9h. 55m. 36s.

**A NEW EXPERIMENT ON MAGNETIC ATTRACTION.**—E. Piazzoli has written a paper to show that the attraction of elder pith by the magnet, as observed by Ader, depends probably on the presence of small particles of iron.

## Foreign Industrial Notes.

Germany seems to be obtaining a monopoly of the iron trade. Owing to cheap raw material, low wages and the ease and low rates of water carriage, the Germans are steadily underselling the English markets.

The men employed at Krupp's manufactory are working night and day in supplying orders for large guns from abroad. Roumania has ordered 100; Greece, 700; Sweden, 50; Holland, 120, and Italy, 400. In the presence of facts like these it is a little difficult to perceive from which direction the millennium is approaching.

Several organizations have been effected by British workmen, having in view emigration to the United States, just so soon as the movement may be made with safety. As a rule these workmen are in employment and are not prepared to give up a surety without tolerably certain employment on this side that will be permanent.

## MINING SHAREHOLDERS' DIRECTORY.

Compiled every Thursday from Advertisements in Mining and Scientific Press and other S. F. Journals

### The Mechanics' Fair.

At the meeting of the Trustees of the Mechanics' Institute, held on Tuesday evening last, they awarded privileges for the next Mechanics' Fair, as follows: Printing, Dewey & Co.; eoda, G. C. Thompson; candy, D. S. Ciphers; cider, G. C. Thompson; ice cream and restaurant, Vienna Bakery; pop corn, D. S. Ciphers. An effort is being made by the Trustees to get for exhibition the smaller of the two telescopes now being built for the Lick Observatory at Mount Hamilton—the instrument having nearly completed. As several inventors have been endeavoring to perfect a flying-machine, the Board of Managers have decided to offer \$1,000 for the first successful attempt made with such a machine at the Mechanics' Pavilion at the next fair. The fair will open on the 2d of August. About three-quarters of the space included in the building has been already assigned to intending exhibitors. This year the managers will give exhibitors the space needed for a proper display of their exhibits free of rent. The managers represent that the prospects of the coming exhibition are unusually brilliant.

It will be noticed that the publishers of this journal have been awarded the privilege of publishing the *Fair Daily*. This privilege we have had for a number of years consecutively, which is the best guarantee that it has been done to the satisfaction of the management and the patrons of the fairs.

A NEW ORE PULVERIZER.—Mr. I. W. Tustin, of this city, has invented an ore pulverizer which is claimed to be a great improvement on anything in that line hitherto introduced. The simplicity of its construction as well as the small amount of power required to work it, are the most essential points to recommend it to general use. A model of this pulverizer capable of working about 6 tons in 24 hours is at present in operation at the ore sampling works of Messrs. Hofmann Bros., 415 Mission street, where it has been worked to their entire satisfaction, and where it may be seen and inspected by all who are interested in mining and milling machinery. Mr. Tustin at all times will cheerfully exhibit and explain the merits and advantages of his invention.

FRUE CONCENTRATORS.—The Providence M. Co., Nevada county, which is now putting up a 40-stamp mill, has decided, after thorough investigation, to adopt the Frue concentrators, and has purchased 16 of these machines. All the other concentrators in the market were examined, and they decided on adopting it, because of its greater efficiency. The superintendent of the Murchie company, reports that the annual repairs on the concentrators are only \$10 a piece.

### The Mining Share Market.

There is not much to say about mining stocks. Our tables give full information about fluctuations. The number of pending mining assessments is now smaller than it has ever been in the history of the mining share market. There are now but 28 mines with assessments pending on their stock. Of these only 10 are Comstock. At the old bonanza mines they now have an excellent circulation of air everywhere from the 2000 down to the 2500 level, and are beginning the work of exploring the ground lying between those points. The drift north in the California, 30 ft. below the 2000 level, is still following a seam of quartz. The *Enterprise* says: Again there is delay at the Combination shaft, but this time it will be short. It must be that they will soon find all those weak points disclosed by actual work but hidden to mathematics. In the starting up of the Virginia City and Gold Hill water-works there was the same trouble in Washoe valley at and near the bottom of the inverted siphon formed by the high iron conducting pipe, but when practical working had corrected the faults of figures all went well, and has been going well and smoothly ever since. So it will eventually prove with the hydraulic pump. The principle is all right, but faults are found in the calculations as regards the strength of material employed in the construction of the apparatus. Actual work finds the point where the greatest strain comes, and corrects the errors made in calculating the strength of the metals employed.

### Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Northern Belle, June 8th, \$6,481; Mount Diablo, 7th, \$8,049.53; Christy, month of May, \$28,612; Northern Belle, 8th, \$23,325; Christy, 10th, \$6,799; Germania, 9th, \$1,800; Hanauer, 9th, \$2,500; Christy, 9th, \$7,185; Horn Silver, 10th, \$12,500; Bullionville, 10th, \$2,345;

dency of Wm. Fawc. The ledge is from 18 inches to 2 ft in thickness, which assays from \$40 to \$60 per ton. The shaft is now down about 35 ft. The mine is well spoken of by practical miners of that locality.

FRESNO.

**CHART.**—Fresno *Expositor*, June 11: Considerable excitement has been occasioned by the discovery of rich gravel deposits along the banks of Keyser gulch. The bed of the creek was very rich, and was mined years ago with good results, but the banks above were never prospected to any extent. The deposits now being opened are of a bluish cast, and no doubt indicate the channel of an ancient river. It appears very rich, and should the discoveries prove as extensive as is now supposed, will also indicate a point a short distance east of Canada hill. The croppings show one ledge 8 ft thick with 3 more ledges measuring respectively 6, 4 and 3 ft making into it. There is also a vein about a foot thick that crosses this series. The prospecting is being conducted by means of a tunnel that has just struck the edge of the 3-foot ledge, and will have to run 300 ft to reach the point where they all come together. Here 300 ft of backs will be obtained. A crosscut, is to be run to tap the 4-foot ledge also between the mouth of the tunnel and the big deposit.

INYO.

**BYRIDER AGAIN HEARD FROM.**—Inyo *Independent*, June 11: A clean-up of the anaristas after a three week run, ending June 4th, has produced \$13,000 in gold bullion; \$5,000 of this amount has been shipped from Wells, Fargo & Co.'s office in this place, and \$1,000 from the Lone Pine office, while \$1,000 remains in the hands of the producers, yet to be disposed of. The Taylor mill starts up on Monday, the first of next week, and for at least a month to come the numerous anaristas will continue to run as heretofore.

NEVADA.

**THE ALTA MINE.**—Nevada *Transcript*, June 14: R. B. Symington and J. C. Luckin are developing a promising quartz claim at a point a short distance east of Canada hill. The croppings show one ledge 8 ft thick with 3 more ledges measuring respectively 6, 4 and 3 ft making into it. There is also a vein about a foot thick that crosses this series. The prospecting is being conducted by means of a tunnel that has just struck the edge of the 3-foot ledge, and will have to run 300 ft to reach the point where they all come together. Here 300 ft of backs will be obtained. A crosscut, is to be run to tap the 4-foot ledge also between the mouth of the tunnel and the big deposit.

**CONTRACT LET.**—Grass Valley *Union*, June 19: The Maryland M. Co. has let to Wm. Carlson (he being the lowest bidder) a contract to raise a shaft from the drain tunnel to the surface, a distance of between 100 and 150 ft. The dimensions of the shaft will be 9x4 ft, double compartment. The shaft will be about 800 ft. The contract is expected that the work on the contract, which is to be started immediately, will be completed in 2 months. It is the intention of the company, upon the completion of this contract, to let another for sinking the shaft below the tunnel level to a depth not yet determined upon. The Maryland is yet to be one of the great mining properties of the district.

PLUMAS.

**DISCOVERY.**—Greenville *Bulletin*, June 10: A rich ledge has been discovered near the Cherokee mill on the ridge above the road, not far from the Round Valley reservoir. **SOUTHERN EUREKA.**—From President J. B. Scott's letter every day shows improvement in this mine and in the quality of the ore. The result of the last clean-up was considerably in advance of any previous one, and is calculated to make glad the hearts of officers and stockholders. A. B. Williams, of Reno, succeeds M. B. Bradford as Supt.

**SAYREWOOD.**—This mine is about 10 miles from Greenville, on the north fork of Feather, 5 miles below Bidwell's bridge. It has a small mill of 40 stamps, 20 of which are now doing a very good quality of ore. Supt. Hart received us cordially, and very kindly showed the mill and 4 of the tunnels. There are 9 of the latter, all of which strike the ledge. Col. Lansing, of New York, and C. W. Reed, of Sacramento, two of the principal owners, are to arrive this week, after which it is expected that a number of concentrators will be put in for the purpose of saving sulphurates, of which the ore carries a large percentage. Jesse Carney, formerly of the Plumas Eureka, is the amalgamator, and Mr. Colwell, book-keeper.

**GOOD CLEAN-UP.**—National, June 12: Loring & Leavitt brought into town on Wednesday a very handsome lot of gold. The clean-up for last week amounted to over \$1,700; and for the first two days of this week, \$344. The yield from this mine is steadily increasing.

**NORTH FORK NEWS.**—Lant Hallist, d. who has been over on the North Fork, informs us that the miners in that section are doing a very good quality of ore. Supt. Hart received us cordially, and very kindly showed the mill and 4 of the tunnels. There are 9 of the latter, all of which strike the ledge. Col. Lansing, of New York, and C. W. Reed, of Sacramento, two of the principal owners, are to arrive this week, after which it is expected that a number of concentrators will be put in for the purpose of saving sulphurates, of which the ore carries a large percentage. Jesse Carney, formerly of the Plumas Eureka, is the amalgamator, and Mr. Colwell, book-keeper.

**OFFER REFUSED.**—Some days ago an offer of \$50,000 was made to Loring & Leavitt for their claim at Elizabethtown. As the payment was partly conditional on the product of the mine, the offer was refused; but the owners agreed to take the sum in a yearly annuity of \$1,000, and the offer was accepted. The offer was made by a party who wished to purchase, having thought the matter over, concluded to pay that sum. Mr. Manson, of Greenville, who represents these people, came over from Greenville Wednesday ready to pay the deposits and make the trade on those terms, but the owners now decline to sell. The yield of gold is increasing all the while.

SAN BENITO.

**OUTLOOK.**—Pacific *Coast*, June 10: Important discoveries have recently been made in the Pico mine near Erie, and the outlook is quite promising for the future. Much of the quartz now taken out is quite porous, and is very easily drilled and worked. The quality and the quantity of the quartz is steadily improving, and the outlook is now greatly strengthened in the belief that they have a good property. A larger force will soon be at work. At the San Benito mine some new apparatus has recently been tested which gives decided satisfaction. There is abundance of paying rock in sight. From other mines in different parts of the county we also have quite encouraging reports.

SIERRA.

**RIEN.**—Greenville *Bulletin*, June 10: Mr. E. M. Prime, just in from Sierra county, gave us a call yesterday, and reports that from the Rainbow quartz claim there was taken out 20 ounces of gold in one day; that the owners had already taken out \$70,000, and had been offered and had refused \$1,000,000 for their claim.

**QUIT WORK.**—Mountain *Messenger*, June 11: Nearly all the workmen in the Bald Mountain mine, Forest City, quit work on Monday on account of a reduction of the price of labor. The price of drifters was reduced from 60 to 50 cents per carload. Main tunnel from \$4.50 to \$4.00 per foot; gangways from \$3.50 to \$2.00; air course from \$2.00 to \$1.50. On this striking work has not been reported, the men asserting that they cannot make wages at these reduced prices.

**HASKELL PEAK.**—Haskell Peak Co. has their main tunnel in 1123 ft. A contract has just been let for sinking to the bedrock. The shaft is down about 15 ft, in fine red quartz gravel, that evidences good pay ahead. The most singular feature connected with this tunnel is that the air is just as good at the face of the drift as at the bottom, without the aid of any air pipes or shaft. An assessment of one cent has just been collected, which, after all the debts have been paid, leaves a handsome surplus in the treasury for future operations.

**GRAVEL.**—We are assured that the Savage Co. have struck a gravel prospect. From what we have never doubted but that the company would. From what we can learn we should judge that a gravel was struck.

**ARRIVAL.**—The Arizona tunnel is in nearly to the shaft. A company formed by the late Alfred Smith, has arrived in Sierra City, and says he will commence work immediately. The company has a large tract of mining land located.

The Bonanza mine, Howland Flat, is paying hand-somely, and the channel widens as they go on. The Arizona tunnel is in nearly to the shaft. They had a slight cave in this tunnel last week, which has delayed them somewhat.

**MORRISTOWN.**—J. M. Elko was down this week. He said that near the whole of Craig's Flat is now away, and would be hardly recognizable by an old settler. There are still 500 inches of water available for milling purposes. Supt. Swan is busily engaged, with a large crew, developing the extensive hydraulic diggings recently purchased by Eastern capitalists. Prof. Blake, lately up here on a flying visit a few days, owns one-quarter of this property, and through his influence the sale of it was effected. The projected new road, from Morrystown to Fort Wile will probably be made some time this year.

TRINITY.

**TAYLOR FLAT.**—Trinity *Journal*, June 11: Of all the mining industries on Trinity river none give so much promise as the Trinity hydraulic gold mine at Taylor flat. The company is now out of debt and has reached some rich ground which is paying well, as we learn from reliable authority. It is expected that this property will next season take rank with the best.

TUOLUMNE.

**CONFIDENCE.**—Tuolumne *Independent*, June 10: There are at present quite a number of men employed in the mine, which is turning out some very fine rock. The mill is kept running day and night, with bright prospects, from the amount of quartz in sight, of keeping her 20 stamps busy for a long time to come.

NEVADA.

WASHOE DISTRICT.

**SIERRA NEVADA.**—Virginia *Enterprise*, June 12: On the 2500 level east crosscut No. 1 has been advanced 36 ft; No. 2 has been advanced 17 ft, and No. 3 is in a total distance of 34 ft. During the week 307 tons and 1,000 lbs. of ore, assaying \$36 per ton, have been raised.

**HALE & NORCROSS.**—Owing to the intense heat the work throughout the mine has been very much retarded. Completed repairs to the pump-rod and started the pumps yesterday.

**CON. VIRGINIA.**—On the 2300 level we are enlarging the connection between the Best and Belcher winzes and upraise between the 2000 and 2300 levels.

**UNION CON.**—The joint Sierra Nevada winzes (2500 level) has been sunk and timbered 13 ft; also cutting out tank shaft at 2000 level.

**OPHIR.**—On the 2500 level the joint California winzes has been sunk and timbered 12 ft. The joint Mexican east winze has been sunk and timbered 15 ft.

**MEXICAN.**—On the 2700 level the joint Ophir east crosscut has been extended 26 ft.

**UTAH.**—Since last report the incline has been sunk and timbered 15 ft. This ground in the bottom is working better.

**UTAH.**—During the past week we have sunk and timbered the shaft 27 ft. Total depth, 2,640 ft. The rock is harder.

**CALIFORNIA.**—On the 2500 level the joint Con. Virginia east crosscut has been advanced 32 ft, and the joint Ophir east winze has been sunk and timbered 12 ft.

**UNION SHAFT.**—Are cutting out a station at the 2700 level and easing at the 1000, 2000, 2400 and 2500 stations. **YELLOW JACK.**—We reached the 2800 pump on the 7th inst.; repaired the same and resumed pumping. We are now preparing to lower the water to the 2525 station, where we have a drift connecting with the Belcher 2700 level. On our 2700 level during the week we have repaired and raised the grade of the track, and placed pipe to conduct water to the 2800 tank.

**NEW WELLS-FARGO.**—The lowering of the water in the shaft has been more rapid than was anticipated, on account of the water receding from the 300 ft level. This difficulty is being steadily overcome.

**SUTRO TUNNEL.**—Drain boxes covered, last report, 17,000 ft; drain boxes covered since last report, 684 ft. The covering of the drain boxes has been finished. Single line of large boxes put in, last report, 1,006 ft. This large boxes are now finished up to a point 18,721 ft from the tunnel entrance. The work of the week the usual repairs have been made along the main line. Flow of water from tunnel entrance equal to 4,752,000 gallons per 24 hours. An excavation for a carriage switch, 55 ft long, has been finished. Between the end points of this curve, for a distance the drift was run 10 ft wide for the carriage station.

CAÑADILLA DISTRICT.

**NORTHERN BELLE.**—True *Pisgah*, June 11: At a point 45 ft above the 2nd, near the center of the mine, a body of good average ore has been opened. The 12th level shows finely, turning out considerable ore of good quality. The levels above the adit are producing as usual. Both mills are running steadily. Bullion shipments on June account to the 13th inst. \$2,325. The face of the north crosscut from the bottom of the winze, from the third level, is in a ledge of low grade ore and shows considerable improvement; total length, 27 ft. The west drift from the north crosscut, on the same level, shows some improvement and looks well. The slope on the first level shows a body of free ore about 35 ft long, and averaging 6 ft wide, assaying over \$100 per ton. On June 7th the mill, assaying to \$8,049.55 was shipped, and on June 10th, \$6,799.86.

CHEERY CREEK DISTRICT.

**ANOTHER STRIKE IN THE STAR.**—White *Pine News*, June 11: We learn—though from no official source—that another very important discovery has been made during the past week in the lower workings of the Star mine. It is every day becoming more transparent that the Star is destined to prove one of the most permanent as well as valuable mining properties in eastern Nevada.

**BULLION.**—The Star Co. shipped through Wells, Fargo & Co., for the week ending June 4th, bullion the gross value of which was \$3,656.08. The Exchange shipped one bar on the 7th valued at \$1,300.

ESMERALDA DISTRICT.

**THE HUMSBOLDT WEST.**—Esmeralda *Herald*, June 10: The crosscut on the 100 level shows the east ledge to be 23 ft wide, with not a stratum of waste rock. The lowest assay gives about 100 per ton, and the highest goes far up in the hundreds. It is estimated that the average of the entire ledge will not fall short of \$30—some say more.

**THE CORTAZ.**—The incline is now down several feet below the 100 level from the tunnel, making the depth now reached over 200 ft from the croppings. The width of the ledge is the same, and the quality of ore fully as good. This would seem to knock into a cocked hat the silly theory of those not posted on our camp, who have always concluded that our ledges do not go down to any depth before they "pete" out. The fact is, there has never been an instance in the history of this mining district where a ledge has given out. The Cortez owner had worked down until a barren spot in the ledge was encountered, and there stopped. The present company started work where the former owner left off, and in less than 6 ft again came into rich rock, which they have continued for over 70 ft, and yet there is no sign of "pete"ing.

**THE CENTRAL.**—Messrs. Ball & Groh are keeping right on extracting ore of the richest kind from this mine. **THE UTAH.**—Men are now at work cleaning out the old whim shaft and putting in a double set of ladders, preparatory to prosecute work in the mine.

GOOD HOPE DISTRICT.

**GOOD.**—Tuscarora *Times-Review*, June 10: From Good Hope district we have good news. The mill is working well, and if the boys only take out ore to keep it running the future of the district is good.

LAKE DISTRICT.

**CONTRACT LET.**—Ward *Reflex*, June 11: S. A. Winall, Supt. of the Scorpion mine, in Lake district, has let a contract to extend the tunnel 60 ft. Ore of good quality was struck the first shot.

TAYLOR DISTRICT.

**SHIPPING ORE.**—Ward *Reflex*, June 11: The owners of the Monitor mine in Taylor district have commenced shipping ore to Eureka for reduction, which they will continue to do until the mill on Sterpe creek is completed. **HALE.**—Messrs. Briggs, Lyons and McGill, the owners of the Monitor mine in Taylor district, have purchased the

old leaching mill from the Martin White Co., and will immediately move it to the mill site recently purchased by them on Sterpe creek. The mill will be run by water power. Although called a leaching mill it is no part of the purpose of the owners to work by the leaching process. Over 400 tons of good milling ore are on the dumps of the Monitor, and the mine is in such shape that 4 or 5 men can keep that amount ahead of the mill. It now looks like Taylor district will be heard from this summer.

TUSCARORA DISTRICT.

**THE MINES.**—Tuscarora *Times-Review*, June 10: Since the order has been issued by the directors of the Grand Prize to shut down the 600 level, much attention has been attracted to this district. There is not now, nor has there at any time been anything, to discourage live and practical miners from following up or down the work on Tuscarora mines, with the same energy that characterized the labors of Sharon and others in Virginia City. We assert on the honor of journalists, that there is nothing beyond the uncertainty of all mining ventures to militate against the financial outcome of Tuscarora. We have already coined more dollars than have been sent to us. We have drawn very lightly upon the purses of foreign stockholders; we have paid for all our claims; we have not our laborers, who have never reduced as a matter of financial necessity the wages of miners, and have scattered hundreds of thousands throughout the Pacific coast. We have had but few failures in town, and but few "wild-cat mines" have ever been thrown upon the innocent and unsuspecting public. Then we ask, in view of the premises, why is this district, and why this effort to depreciate the real value of Tuscarora? The answer is not obvious, and we must unhesitatingly predict a larger bullion shipment and more active mining operations during the present season than has ever been witnessed before.

WARD DISTRICT.

**REPORTED STRIKE.**—White *Pine News*, June 11: A report reached here Thursday that an important strike has been made in the Paymaster mine at Ward, and that as a consequence the people over there were highly elated, which, if the report proves true, they have good reason to be. We sincerely hope the reported strike may prove a valuable one.

WHITE PINE DISTRICT.

**MINING SALE.**—White *Pine News*, June 11: Rumor was current on our streets yesterday that the Jennie A mine, at White Pine mountain, had been sold to London capitalists for \$250,000. The Jennie A is a base metal mine, and has for years been considered a valuable property.

ARIZONA.

**OLD DOMINION.**—Globe *Chronicle*, June 9: The developments on the properties of this company are indeed of the most satisfactory kind, and nearly every day reveals some new development, proving that the ore in these mines are continuous veins that will last for years. On Tuesday last, in the tunnel on the Old Dominion, they struck the ledge about 60 ft west of the shaft, and have penetrated it to the distance of 3 ft, finding very rich red oxide and green carbonate ore. On the New York and Chicago there seems to be no lack of rich ore; the tunnel at a distance of 60 ft from the mouth a crosscut was run to without striking the south wall. The shaft is down 50 ft with ore on all sides. Two 30-ton smelters are now being built in San Francisco, by Messrs. Prescott, Scott & Co., and will be erected and running as soon as possible.

**THE TARKOMA COPPER MINE.**—This mine has some rich copper glance ore, which also assays high in silver. From a drift in the upper shaft, rich oxides of copper are being taken out, along with considerable glance ore, which is said to be malleable in spots, under the knife point. The cut along up the hillside exposes a 3 ft vein of extremely rich copper ore for 200 ft, a large portion of it being a solid mass of pure copper glance. At the 100 ft level in the lower shaft a crosscut was made, tapping the v-e in and striking rich ore.

**MACK MORRIS.**—The men are still stopping in the third level and taking out the rich ore that was reported last week. Everything at the mine and mill goes on like clock work.

**SILVER NEEVER.**—The south drift on the 180 level to connect with the main shaft, is being rapidly pushed ahead. There is some nice looking ore in the face; the east crosscut on this level is also being driven ahead rapidly and in a more favorable formation.

**MULE MOUNTAINS.**—Arizona *Miner*, June 10: Francis Donnelly, who came in from Tombstone Tuesday, reports mining matters lively in the Mule mountains. He is part owner in the New Year, Southern Cross and other claims there, on the first of which Col. Oerald is putting down a shaft 150 ft deep. He is now down 78 ft, and has exposed a fine body of carbonate ore, which assays an average of \$200 per ton. These claims are very promising, and will undoubtedly add to the good reputation of the Mule mountains district.

**MULE MOUNTAINS.**—Arizona *Miner*, June 10: Mr. M. S. Snyder, who got back from the Meyers district this morning, reports matters very quiet in that neighborhood, notwithstanding the excellent outlook for eventual prosperity. The famous Gunsight mine is awaiting the smelter to be soon erected, and only a very few men are now at work on it and the Western, an adjoining mine. The Yahoo mine, which came in from Tombstone Tuesday, reports working it, and it is idle. Quite a number of prospectors who own claims in that vicinity are steadily at work developing their claims. Wood and water are scarce, and much trouble is experienced by the miners on account of their absence. The future of the district, however, is very encouraging.

**QUARTZ MILLS SOLD.**—Arizona *Journal*, June 13: Sheriff Paul reported yesterday from a party who on Saturday sold under execution the Deere & Townsend quartz mill. The property was bought in by Pedro Aguirre, one of the heaviest creditors, for \$9,000. This mill has a battery of 10 stamps, and is said to be capable of doing as good work as any machinery of the kind in the Territory. Under these circumstances the price at which the property was disposed of was remarkably low.

**CORNER.**—Silver *Reflex*, June 11: The Belcher copper claim was sold Sunday. We found a shaft 20 ft deep, cutting a strong ledge of ore which carries a large percentage of copper. The ledge, where it was prospected by means of a crosscut, is 6 ft wide. The ledge is traceable on the surface for a long distance.

**RIEN.**—In the East Richmond mine, on the 100 level, they are taking out some of the richest ore yet found in Arizona. They take out 100 tons of ore, which is worth, weighing from 75 to 100 lbs. They are shipping ore.

**BULLION.**—By the end of June the total bullion shipments of the Mack Morris will have reached the respectable total of half a million of dollars. This represents less than a year of actual work. It is safe to predict that in another year the above figures will bear no comparison at all with the yield.

COLORADO.

**CLEAR CREEK.**—Chaffo *Co. Times*, June 8: The prospects in Clear creek gulch, from a point about 6 miles west of its junction with the Arkansas river, to the Continental divide, 12 miles farther west, all give promise with development of becoming more or less valuable. Some very rich paying mines will no doubt be opened, from present indications, this season. At the head of the main branch of Clear creek a number of excellent claims have been located, but the unusual fall of snow last winter has made them inaccessible until very recently. It is the intention of the two branches of Clear creek, on a towering wedge-shaped mountain which has been named Middle mountain, are a large number of excellent locations, which with systematic work will develop into good mines. Just below the forks, in a pretty little park, a town has been laid out called Florence, which already contains 10 or 12 houses, and a large store is now being finished. Here the Clear creek is generally called. It is located about 2 miles below Florence, and is surrounded by some really good claims and many fine prospects.

IDAHO.

**COMMENCING.**—Yankee Fork *Herald*, June 4: Oen. E. E. Cunningham, Supt. of the Yankee Fork Con. Gravel M. Co., arrived here from New York Wednesday to commence active operations. He says piling will commence Monday in the face of the bank, which is 60 ft high, and the gravel prospecting from the surface down. Arrangements are also being made to extend the ditch down to the bars, 2 miles below, where one or two little plants will be put to work this summer. Their ditch carries 2,250 inches of water.

**SALMON RIVER.**—Yesterday the furnace was started up. After running 24 hours 30 bars of good, clean bullion were molten, the bars weighing from 100 to 150 lbs each. The average return since has been 8 bars per hour. Nevada and Utah men say that, for the size of the smelter, this cannot be excelled. All of our citizens are jubilant over so fair a showing.

**THE OVERLAND MINE.**—owned by J. D. Woods, has a force of men at work. They are down 55 ft, and have 5 ft of good ore. The ore will go \$100 per ton.

**THE FAITHFUL BOY.**—is running a force. A large amount of ore is out, which will be taken out and worked at the furnace as soon as teams can commence work.

**WOOD RIVER.**—Wood River *News*, June 8: It is often remarked that Wood River is a strange camp, not like others. And it is so. Those who are prepared to stay, if the country "suits them," look around while satisfying themselves, one way or another—and so far, it has been favorable to the new camp—and then they proceed to pre-dwelling places; not brush tents, but good substantial houses. The prospects, one and all say, justify a solid, permanent move in the start, and they do not believe in the mushroom order of business where a country offers so many and such varied inducements to the permanent settler.

MONTANA.

**ALICE.**—Inter-Mountain, June 8: The winze which is being sunk from the 500 level on the north vein has attained a depth of 175 ft, and is expected to connect with the 700 level in about 2 weeks, when, ventilation being provided, a largely increased force of men will be employed in stoping the ore bodies recently opened up. The upper levels are yielding ore in regular quantities, which pulp from \$50 to \$80, and as yet there is no indication of the supply becoming exhausted.

**MAONA CHARTA.**—Preparations are now being made for the development of this mine on a scale commensurate with its size and value. In the shaft-house a gallow's frame of the same size and pattern as that of the Alice will soon be erected and a pair of boilers and an engine of sufficient capacity to sink 1,000 ft have been recently ordered.

**BELL.**—For the past 5 or 6 weeks operations in the Bell have been confined to the sinking of the east shaft and of the winze from the 200 level. The shaft having reached a depth of 300 ft a north crosscut was extended to the ledge, penetrating the footwall at a distance of 6 ft. The face of this crosscut has since been advanced 13 ft from the shaft and is still in ore, the hanging wall not having been encountered. The ore so far opened up is of three grades, the first-class ore predominating.

**CORA.**—The Cora shaft, in which a fine body of ore was recently discovered, and which was erroneously reported to be an incline, is being vigorously pushed downward, having now reached a depth of 170 ft. The ledge in the bottom is 6 ft wide and samples 75 ounces in silver. It carries also a small percentage of copper, but not enough to prevent its being successfully milled after roasting. The product of the shaft alone is now 5 tons daily, and drifts on the vein will not be extended until a depth of 200 ft has been attained. The ore is being shipped to the Silver Bow mill.

**ANSELMO.**—Sinking on the two shafts is being rapidly prosecuted, the west shaft being 320 ft and the east shaft 270 ft in depth. From the 300-ft station in the former the east drift has been extended 50 ft, the ledge being about a foot wider than in the level above, and the ore showing an improved quality.

**MOULTON.**—The Moulton keeps on the even tenor of its way without let or hindrance. The depth of the shaft this morning was 372 ft, the granite in the bottom being of the proper texture for good blasting.

NEW MEXICO.

**CHLORIDE DISTRICT.**—Cor. Tombstone *Union*, June 10: Much has been said within the last few months in regard to the Black range, and in regard to the magnificent finds which it offered to the prospector, especially of Chloride district, which has been pronounced another Tombstone. In view of these facts it may not be without interest at this time to state the result of 2 months' prospecting in the Chloride district. Chloride is situated in the Black range, a spur of the great continental backbone, between the Rio Grande and Mt. Rio Minimes, extending north and south. The district is about 12 miles in length, with one large ledge of flinty, white quartz, broken up here and there into smaller ledges, which can be plainly traced the entire distance. The formation is porphyritic and sedimentary, with an almost complete absence of granite, quartzite and lime. The ore is found in spots and pockets in base, with some horn silver. There are no deep shafts so far, the deepest, the Wall Street, being only 40 ft, and further developments do not tend to improve the camp. On a fair and dispassionate view of that new field of mining enterprise, I am emphatically of the opinion that a second Tombstone has not arisen, and that this district is in little danger of losing its laurels in competition with the Black range.

OREGON.

**RIE VALLEY.**—Bedrock *Democrat*, June 8: Hobbs & Co., have sold their placer claims to Chinnamen. Lum Davis has also sold to Chinnamen, so Lum and Mrs. Lum are flush with coin, and happy. C. M. Foster has been here surveying the Company's ground and tunnels. S. Ottenheimer has been looking after his mining interests on Snake river. The Company's mill is running constantly, its large reserves of quartz in the mine. The indications for continued success are more promising than at any time during its past history.

**ITEMS.**—Democratic *Times*, June 10: Mining items are scarcer than gold dust. Piping is still going on at the Grand Applegate mines. Several of the miners on Foot's creek are still cleaning up. Bills & Armstrong, mining on Bankum, cleaned up \$200 the other day the result of a 14-day run with four hands. Frank Ennis returned from Galice creek last week, from whom we learn that that camp is in statu quo, the miners having gone into summer quarters. J. S. Howard has surveyed the line of the extension of the Sterling M. Co.'s ditch and work will be commenced soon. This makes the ditch about three miles longer, which will then cover the company's vast mining property entire.

UTAH.

**CHRISTO.**—Silver *Reflex* *Miner*, June 8: The Christo Co. is constantly attempting to outdo its previous efforts, and now comes forward and reports the most productive month's run of the mill, with two exceptions we believe—since they started their machinery some 3½ years ago. This is the more gratifying in view of recent events, which could but shake the confidence of those not familiar with the extent and richness of our mines. The company shipped 15 bars of bullion for the month of May, amounting to \$28,612.20.

**STROMONT.**—Repairs at the mill were completed during the week, and it is expected to start its stamps as soon as the ore supply will justify.

**BARBER & WALKER.**—Negotiations are pending with the creditors of the Barber & Walker, which are expected to terminate favorably, when the works will start up. There is sufficient ore in sight in the different workings of the mine to fully justify every reasonable expectation.

**THE STAGE MET A TRAIN OF 36 MULES** the other day which had just left Custer, Idaho, each mule carrying two bars of bullion, the whole aggregating \$177,000.

### Special Exhibitions—Their Great Value and Importance.

Nothing more fully impresses the careful observer of events, in regard to the stronghold which the value of exhibitions of skill and industry has taken upon the public mind, than the innumerable "special exhibits," which from time to time are being held or announced, both in this country and Europe. The demand for this kind of study and advertisement has become so great that exhibitions have now to be classified, in order to find room and space for them. Instead of a general exhibition of all the industries of a country at one time and place, these industries are divided up into class exhibits. For instance, we have just had an exhibit of the milling industry of this country, at Cincinnati, and we are soon to have one of the cotton industry, at Atlanta, while another exhibit of food industries is promised, and so on through the entire catalogue. A great advantage gained from these class exhibitions comes from the fact that a full exhibit of any special class becomes necessarily national or international in character, and brings together at a given point the entire experience of the country, and all persons who are largely interested in that specialty. The general beneficial results are thus greatly increased.

#### The Flour Miller's Exhibition,

Which was held at Cincinnati about a year ago, and which was one of the first efforts of the kind in this country proved a most decided success and aroused a wide interest in milling industry all through the country. Although it did not pay expenses, it was considered of so much value to parties most directly interested that the \$12,000 or \$15,000, required to make up the deficiency, was readily raised.

This great gathering of experts and scientists and the opportunity offered for comparison of methods and means, cannot fail of being greatly beneficial in advancing the interests of this important and growing industry.

#### A Brewer's Exhibition

Was held in London over a year ago. Besides an exhibition, this was also a trade mart, and the transaction of business reached fully a million and a quarter of dollars in a single week. Some 300 exhibitors showed over 2,000 different kinds of exhibits. The United States entered the lists in competition, and with most unexpected results. The exhibits of beer offered by Americans were received with much satisfaction, and since that time it is reported that American beer has become very popular in London, so much so that the *Pall Mall Gazette* characterizes it as a "bright and pleasant article," and warns English brewers of the dangers that may be expected from American competition in this line.

Agricultural Hall, in London, a few months since, was the scene of still another exhibition of quite a novel character, in which our own country took quite a prominent part. It was a display of the multitudinous

#### Food Products of Europe, America, and Australia.

The exhibition was designed mainly with a view of bringing under notice of the English public the many varieties of preserved fish, vegetables and fruit, together with the best methods of preparing them for the table. In addition to this, there was also a large display of culinary and domestic apparatus of the most approved and ingenious kinds. In regard to this exhibition, the *London Times* said that "America naturally took the lead." Australia was, in comparison, poorly represented. The effect of this exhibition can scarcely fail to be of great advantage to this country. Some two years ago, Mr. Atkinson, of Boston, suggested that there should be held at some convenient point in this country, an exhibition of

Cotton, the Cotton Plant, Machinery, Etc. At which the fiber and cotton goods of any description, together with the machinery for its manufacture; also cotton seed oil, oil meal, machinery for ginning, pressing, cultivating, etc., should be shown. He also suggested that it should form a part of the New York World's fair in 1883; but the idea grew so rapidly and took such large proportions that it was soon determined to make it a special exhibit at Atlanta, Ga., in October next.

We have now before us the full programme, with a view of the magnificent exhibition building which is in process of erection, and the elegant grounds with which it will be surrounded. It has fairly passed from a merely national feature and has assumed the character of an international exhibit. The enterprise will usher in a new era for Southern enterprise and industry, and presents one of the surest indications that the people of the South are taking a new departure in a more determined effort to rely upon themselves. A part of the building will be fitted up with the most improved cotton manufacturing machinery, all of which will be in operation, while a portion of the grounds will show the cotton in all stages of growth, from the young plant to the matured boll, with the pickers at work. Assurances have been received from English manufacturers and machine builders that they will be there in force. Japan and China and India will also be fully represented. The town of Atlanta has subscribed \$35,000 to meet any deficiencies that may arise over and above the necessary disbursements. Three New York firms have also

subscribed \$10,000 each, while numerous other parties have subscribed in smaller amounts.

A Second Exhibition of Building Material Was held in London in April last, continuing two weeks, which has been pronounced quite a success. The exhibit included architecture, construction, engineering, decoration, furniture, etc. Another exhibit of the same character is to be held in Brunswick, Germany, commencing July 1st. The notification of this exhibit reached the United States at so late a day that

and a very good show of machinery. The object of the exhibition was more to promote a better understanding of mutual interests than to add to the practical advance of the business. It partook more of the nature of a convention than that of an exhibition. But future exhibitions will probably assume more of a practical nature, and be designed to give a greater impetus to the rearing of sheep and the manufacturing of wool to the end, that we may grow at home the 50,000,000 lbs. of wool which we now import to keep our woolen looms in motion.

MAP OF SONORA, MEXICO, AND SURROUNDING COUNTRY.

no special effort will be made by our people to take any part in it. Had time permitted, the opportunity would have been a very favorable one for certain lines of manufacture, such as builder's hardware, plumber's goods, sashes, doors, blinds, etc.

#### The Carriage Builders.

Which are now a numerous guild, have held several conventions, and in October last, at their convention in Chicago, introduced an exhibition department, which will no doubt lead to an early and full exhibition of this great industry.

#### The Exhibit of Sheep and Wool

At Philadelphia a year ago brought together a large number of breeders and manufacturers,

The producers and manufacturers of the United States are gradually making every department of mechanical industry, one after another, their own, not only sufficiently so to supply the home demand, but also to be able to compete with the leading European nations for the general supply of the world. Europe, therefore, is taking the lead in class exhibitions. Besides those already referred to, we notice calls as follows:

An International Electric Exhibition at Paris, from the 1st to the 15th of August next, to be followed by a congress or convention the month following. The exhibition to be under the patronage of the French Government, the design being to bring together from every corner every species of apparatus which is designed

to develop, transmit, or otherwise utilize electricity.

An Exhibition of Machinery for Trades and Dairy Purposes will be held at Altona, near Hamburg, Germany, from August 18th to October 17th, 1881. The object of this exhibition is chiefly the improvement and development of the smaller trades and the dairy. It will consist of four groups, as follows: 1st. Power machines for trades. 2d. Work machines and tools for trades. 3d. Products of trades, manufactured by the machines and tools of 1st and 2d, and 4th, machines and implements for dairies. It is expected that many of our custom machine tool makers will compete in this exhibition.

A Balneological Exhibition was opened at Frankfort-on-the-Main, Germany, in May last, and will be continued until September next. This exhibition, as the name imports, is designed to illustrate the various systems of bathing and bath appliances, and kindred matters.

A Universal International Educational Exhibition is announced to be held at Brussels for 1883 or 1884.

The growing popularity and success of these modern industrial gatherings sufficiently demonstrates their increasing necessity, and it may be assumed that the nation which neglects such opportunities will lag far behind in the race for supremacy and power, both physical and intellectual.

### Sonora, Mexico.

The rich country of Sonora, the trade of which will probably be controlled by California, is about to be awakened from its lethargy by the screech of the locomotive whistle. Hundreds of miners are looking toward it as a territory where fortunes are to be made. The country is so closely connected, geographically and commercially, with Arizona, that we deem it proper in this issue to reproduce a map which shows the principal towns and mines, and this line of the proposed railroad to Guaymas. This is the Sonora railway. The outline map herewith presented, shows the location of the principal rivers and towns of the section of country through which the surveyed lines of this railway pass. The Mexican government has manifested its desire to encourage an enterprise of this kind by granting to several individuals, resident in San Francisco and Mexico, a concession whose terms are exceedingly liberal, comprising exemption from import duties and State and general taxes for a term of years, free right of way, a land grant of some 22,000 acres per mile, and other important privileges.

In addition to the main line, as laid down in the map, a branch line is projected, starting a short distance south of the Arizona border and running eastward through Mexican territory, across low Sierra Madre to the Rio Grande at or near El Paso, connecting with the Atchison, Topeka & Santa Fe railroad, the Denver & Rio Grande railway, the Texas & Pacific railway, or some other of the lines stretching out toward that focal point. The line at present under consideration, from Guaymas northward, passes through the heart of Sonora, a State whose mineral and agricultural resources, but partially developed, are superior to those of California, with a climate of great salubrity and an abundant rainfall to mature at least one crop a year, without irrigation. The distance from Guaymas to the border by the easternmost of the three surveyed routes, is 265 miles, and the cost for a broad gauge road is estimated at but \$3,500,000, or an average of but little more than \$13,000 per mile. This low estimate is based on the exceedingly favorable topography of the country through which it passes, the cheapness of Mexican and Indian labor available (which is less than the Chinese labor of California), the low cost of importing material under the exemption of duties granted by the concession, and other favorable circumstances.

The terminal point for the railway on the Gulf of California, 1,530 miles by water from San Francisco, is eminently the best on the western coast of Mexico, being superior to either San Blas or Mazatlan, and because of the trade winds, particularly desirable as a port for the trades of the East Indies and China. The bay consists of an inner and outer one, in all four or five miles in length, almost completely sheltered from the winds by the bold heights of Pajaros on the east and the islands of Terra Firma, San Vincente and Petayae on the west, leaving the channel narrow and deep between them. The tides are irregular, being governed by the winds of the gulf, seldom rising and falling more than four or five ft.

The harbor is capable of giving good anchorage to 200 vessels. The town of Guaymas contains some 7,000 inhabitants, and has an active trade, as it is the port of entry for nearly the whole country. Hermosillo is 100 miles from Guaymas, on the line of the proposed railway, and is the most considerable town on the route. It has about 1,200 inhabitants.

Surveyors are now engaged in running a line from the Southern Pacific railroad to an undetermined harbor, at the head of the Gulf of California, above Guaymas. This is supposed to be Point Isabel. The men are now at work, so that the exact route has not been definitely determined on. By looking at the line map and then at the large map of Arizona in this number of the Press, a good idea of the "lay of the land" will be given.

THE Charles Dickens mine, in Idaho, is spoken of as one of the richest on this coast.

## Arizona's Climate.

The following item, which we take from the *Arizona Miner*, will answer questions about the climate of the Territory:

In justice to Arizona, her newspapers cannot too often call attention to the mild, healthful climate of her mountains, foothills, mesas or table-lands, and higher valleys. Take, for a sample, the section of country around Prescott, ranging from 3,000 to 8,000 ft. above the level of the sea. Here, snow rarely falls to a great depth, even on the highest points. As for snow-drifts, they are almost unknown. Last winter was, of course, milder than most of its predecessors. Citizens of the lower valleys, who were here in January, February and March, marveled at the delightful weather, of a town that is nestled among pine-clad hills, about 6,500 ft. above the level of the ocean. The Legislature, which assembled in Prescott early in January, sat, in a large wooden building, with doors and windows open, two-thirds of the time. Soon after the close of the session some two ft. of snow fell, but it did not remain long. Since then we have been blessed with delightful weather. In May the thermometer at midday rarely indicates 30° in the shade, and the nights are cool enough to compel the use of two and three pairs of blankets. Persons who sleep in the open air are rarely, if ever, attacked by sickness of any sort, nor are those who snore in houses afflicted.

While boasting of our mountain climate, it is well to state that while the low valleys of our largest streams are, in summer, rather warm, winter in such valleys is a season of enjoyment, snow is almost unknown and hard frosts are not frequent.

Added to these blessings of climate, or, rather, climates, most of the water is good; earthquakes, destructive floods, tornadoes and other destructive phenomena of Nature have never visited the Territory, so that taking all in all, Arizonans should be the last people in the world to growl at their country.

## Saddle Mountain Coal Fields.

The newly discovered coal fields of Saddle Mountain, though not so extensive as those of Deer creek, produce equally as good coal and the same kind—bituminous—which bears every indication of being an excellent coal to coke for smelting purposes. These fields are situated about six miles east of San Pedro river, and four miles south of the Gila, on the line of 33° north latitude, according to Eckhoff and Rieck's map of Arizona for 1880. It is a little south of east from Florence, and a little east of south from Globe, and about 12 hours' ride on horseback from the latter place.

It is approachable with wagons without any grading, having a natural road right to the mines. There are now about 25 locations made of 160 acres each. Many of these claims are now being vigorously prospected with such means as the prospectors can command. Some of them are showing good coal and others looking very favorable. There are quite a number of veins all striking in the same general course, but as they lay almost flat, but few crop to the surface.

**AVERILL MIXED PAINT.**—It would hardly seem that the simple idea of preparing ready-mixed paint for general sale would create such a revolution in the use of paints as it has done. Before the Averill mixed paint came on the market, people had to buy lead, oil, color and dryers separate, and mix the paint themselves. As this required skill, few attempted it, but hired painters to do the work. Now, however, any small job of painting can be done by mixing a quantity to suit of Averill paint, which is ready mixed and prepared for use in any color. It is also purchased in large quantities by consumers who get a pint of uniform grade of excellence. This pioneer in mixed paints is composed of pure linseed oil, pure white lead, pure zinc and the best colors for tinting, which, by the patented process of manufacture, are united to produce a paint which is at once beautiful and durable. The "soluble glass" uniting the oil and pigments, the whole mass dries with a hard, rich, glossy appearance; and it will not chalk or peel off. The paint can be scrubbed or washed as occasion requires, when its freshness will be renewed. At the office of the general agent for the Pacific coast, O. S. Orrick, 403 Market street, we recently had occasion to note the great variety of colors and tints in which this paint is now mixed. Every possible shade is prepared, and it is put up in large or small packages, so one can procure the exact quantity required, without loss from waste.

**SILVER ORE ON THE TREES.**—The Wood River News tells: "Joe Bush, the prospector, who was called away to his home in Ogden suddenly last week, by sickness in his family, left a specimen with us which is a curiosity indeed. It is a veritable petrification of fir bark, and adhering to it as closely as metal to wall rock, is a chunk of pure galena ore, evidently rich in silver. This establishes the future wealth of the Wood River country beyond all doubt, for where one can abate out of the trees 300-ounce ore, it is a safe bet that this is a better region for the poor man than a placer country. The specimen is on exhibition at this office. Now, let our hostile exchanges trot out a more profitable region, and we'll join the gang to open it up."

## USEFUL INFORMATION.

**PRESERVATION OF INDIA RUBBER UNDER WATER.**—Great losses are often experienced by the users of India rubber tubing, on account of the brittleness which it often acquires in use. A writer in *Dingler's Journal* gives an encouraging account of his success in remedying the difficulty by laying the pipes in water which is often renewed. Even the thickest and stiffest tubes remain soft and pliable without any perceptible diminution of elasticity, and he has been unable to discover any trace of injurious change. For some uses he soaks the pipes in melted paraffine. When they are kept in water they undergo great changes of color, and upon cut surfaces they often appear greasy and bleached, but all the changes seem beneficial rather than otherwise. Thin rubber bands, however, often become so brittle that they can be easily rubbed into small pieces by the fingers.

**TESTING LUBRICANTS.**—A French expert, M. A. Remont, tests lubricants by the following method: He dissolves them in bisulphide of carbon, whereby soap, etc., remain behind. Fifteen grams of the oil obtained after evaporating the solution of bisulphide of carbon are treated for half an hour with 15 cubic centimeters of caustic soda (36° Baumé) and 15 cubic centimeters of alcohol (90%). The oil which cannot be converted into soap in this manner is weighed. The alkaline solution is warmed to remove the alcohol. It is precipitated with a solution of chloride of sodium filtered and washed. The precipitate is again treated with bisulphide of carbon. The mineral oil and resin remaining behind is weighed.

**BLEACHING IVORY.**—An English paper gives the following as a recipe in Sheffield for bleaching ivory for cutlery handles. The mode of procedure is as follows: Place, say, 2 quarts of peroxide of hydrogen in a stone pot, adding 4 oz. liq. ammon. fort. 880°, immerse the handles, and put over a common shop stove for 24 to 30 hours; the handles are then taken out and gradually dried in the air, not too quickly, or they would split. The deep color of the ivory is removed and a beautiful pearly-white ivory results when polished. The ivory is previously treated with a solution of common soda, to get rid of greasy matter and open the pores.

**IMPROVED CANNINO BOXES.**—A very simple and neat improvement has been effected in the preparation of the tin boxes now so extensively used for preserved foods. The body of the box has a beveled rim, upon the slope of which the cover is soldered. When the cover is smartly tapped round the edge it is expanded and the solder joint broken by the wedge action of the bevel. The box is thus opened without injury to the lid, while the present inconvenient and even dangerous process for cutting open these air-tight cases is entirely avoided. The improvement involves no additional cost, and the soldering is applied externally.

**SYRUP THAT WILL NOT FERMENT.**—O. Schlickum, in *Pharm. Zeit.*, strongly recommends an addition of 10% of alcohol to the water with which the ingredients are to be extracted. He has never seen syrup prepared in this way ferment. The best proportion of sugar to the liquid he finds to be as follows: Syrups made with a more or less alcoholic menstruum, three parts of sugar to every two parts, by weight, of liquid; syrups made with water alone, five parts of sugar to three parts, by weight, of liquid; fruit syrups, nine parts of sugar to five parts, by weight, of liquid.

**ENORMOUS PHOTOGRAPHS.**—The claim is made for Australia of having produced the largest photographic pictures in the world. These magnificent specimens of the art—not only in point of size, but in respect also of quality—were taken by Herr Holtermann, of Sydney; they are mounted on an endless band of paper, strengthened by linen, and are nearly 100 ft. in length. Among the subjects are two colossal panoramas of the cities of Sydney and Melbourne, each of about a dozen sheets joined together in one harmonious tone and depth. One picture, printed from a single negative, was five by three feet.

**STRATENA, the cement**, whose wonderful powers are so frequently exhibited upon the streets, is probably only the old Armenian cement. This is so strong that it will hold jewels in place, and is used for this purpose by the Armenian jewelers, who merely flatten the settings of their precious stones and then stick them in place upon the metal with this cement. It is made by dissolving isinglass in alcohol along with gum ammoniac. When well made it is perfectly transparent.

**REMOVAL OF FUSEL OIL AND CLARIFICATION OF LIQUORS.**—A few years since the following process was patented in Germany, which is now again recommended as standing the test of practice, for the above purpose: Eight litres of the liquor, tincture, elixir, etc., are agitated for a while with a mixture of 30 grams pure starch, 15 grams finely powdered albumen and 15 grams of powdered milk-sugar. After 24 hours the liquid will be found free from all fusel oil, of a brilliant transparency and greatly improved in taste.

**IMITATION LEATHER.**—The Japanese make a paper to imitate leather, in which the surface has every appearance of a finished skin, with extraordinary firmness and elasticity, and it can be subjected to washing without any injury from the water. These peculiarities are not so much due to the superior quality of the material as to the mode of manufacture, the surfaces remaining intact, even when the paper is very thick, while with us paper of this kind soon loses its firmness, and the grain is impaired. Japanese leather paper is made extensively at Flingawa, near Yeddo, the capital of the empire.

**HARVESTER HEADER.**—Don C. Matteson, Stockton, San Joaquin county, Cal. Dated May 3, 1881. No. 241,041. This invention relates to certain improvements in that class of grain harvesting machinery known as headers, and it consists in a combination of devices, by which the inventor is enabled by one set of gearing to drive both sickle and draper, and to throw either or both out of gear whenever desired, the draper being stopped while the sickle continues to run, or both may be stopped altogether. The advantage of this is greater simplicity of mechanism and a considerable saving in expense.

**TO REMOVE OIL THAT HAS DRIED UPON IRON OR BRASS.**—To effect this without scraping, a number of plans can be suggested. Ammonia (spirits of hartshorn), soda or soda lye, spirits of turpentine, a mixture of alcohol and ether, or benzine (petroleum spirit), may be used, and any one of them may be found to answer the purpose. The use of alkali (ammonia or soda) will probably prove the most effective; but it must be used cautiously, on account of its corrosive action, and afterwards thoroughly removed.

**TO POLISH BRASS.**—Pulverize a sufficient quantity of sal-ammoniac very finely and moisten it with soft water, rub the paste on the brass; which should be warmed meanwhile over some clear coals of wood; then rub dry with a soft leather, dusted with a mixture of bran and Spanish white. Another method is to wash the brass with a solution of one ounce of alum boiled in a pint of strong wood ash lye; when dry, polish with fine tripoli on a soft chamois leather.

## GOOD HEALTH.

## Cure for Whooping Cough.

Vapors from Purifying Boxes in Gas Works.

We have already given in these columns, the substance of the information contained in the following communication to the *New York Sun*; but we are now requested by a gentleman of this city who has tried it and found it successful, to give the article entire. The advantage of a prolonged visit to the gas works by any person afflicted with the whooping cough is well known, but it will be seen that the same benefit may be readily obtained by persons at their own homes.

TO THE EDITOR OF THE NEW YORK "SUN":—A friend sends me a slip cut from a recent edition of your journal, inquiring for a reliable remedy for whooping cough. I am enabled to give the desired information after actual experience in my own family, and through the equally favorable experience of more than a score of friends and neighbors who have tried it.

It is well known to most intelligent people that exposure of patients to the vapors arising from the purifying boxes in the gas works almost invariably relieves the terrible paroxysms, and, after repeated visits, cures have been frequently effected. This discovery was made by a physician of Paris, about 15 years ago.

The fact was published, and soon after visits began to be made to the Manhattan, New York, Brooklyn and other gas works, on the recommendation of our medical men. An epidemic of whooping cough raged in Newport in the winter of 1878. Over 200 patients, between the ages of two months and 75 years, visited the gas works. The treasurer of the company, Wm. A. Stedman, Esq., states that nearly all were benefited, and some were undoubtedly cured.

About that time the child of a distinguished chemist in Providence, R. I., was seriously ill with this terrible disease, and too weak to be taken to the gas works. The father procured a quantity of the liquid hydro-carbon deposited by condensation in the bottom of the purifying box, and vaporized it in a metal dish in the closed room of the little sufferer. Almost immediately it revived, the spasms were checked, and after a few days the child recovered and was as well as ever.

Microscopists have recently discovered that the cause of whooping cough (pertussis) is the rapid aggregation of bacteria under the root of the tongue. These must be destroyed before relief can be obtained. To this end such powerful medicine as quinine-bromide is given; but even that fails to reach the seat of the disease. Of course the ordinary expectorants are absolutely useless; change of air is rarely curative; hence the rapidly increasing percentage of deaths from this disease.

The New York Board of Health report for 1875 has a list of 489 deaths from whooping cough in that city. The deaths weekly in London, England, are from a minimum of 60 to a maximum of 220, over 6,000 annually.

Physicians generally inform the anxious parents that whooping cough must take its course, as a remedy is unknown, and they can only slightly relieve it; that the incubation and increase in violence will occupy six weeks, and from six weeks to six months will be required before it is entirely removed. The whoopings usually increase regularly in number from day to day to the fifth week, often equalling forty times in 24 hours. Very rarely is this disease preceded by any other, but so great is the strain upon the system that frequently it is followed by pneumonia, in which event death often ensues. A fatal termination is more generally the result of absolute physical exhaustion due to the great strain consequent upon the oft-recurring paroxysms.

A few years since my youngest child, never before ill, was stricken by this dreaded disease. The best medical talent was obtained, every known remedy tried, most watchful care constantly exercised, but without the slightest avail. The child actually coughed itself to death. With all the grief of this sad experience still fresh, in April, 1879, we were alarmed by a new incursion of the destroyer. Our children, five and seven years, were attacked, seemingly with the severity of the preceding case.

It was then I learned of this Providence chemist's discovery, and that simple but ingenious apparatus had been invented by which the hydro-carbon (by analysis found to be cresolene C<sub>6</sub>H<sub>5</sub>CH<sub>3</sub>O), could be evaporated in a closed room. I immediately procured both. The apparatus is a metal stand six inches high, supporting a cap, holding half an ounce of cresolene. The heat is applied either by a petroleum night-lamp or gas, vaporizers being made to attach to an ordinary gas-burner.

Cresolene is a rose-pink liquid, with a boiling point of 397°. It is not unpleasant in odor, but, on the other hand, is extremely grateful to anyone with the least bronchial or catarrhal affection.

In three minutes after the lamp was lighted, the vapor of the cresolene was diffused in every part of a room 15 by 20 ft. In 10 minutes the children manifested evident relief, recovered from their dull exhaustion, and were playing on the bed, even laughing aloud in their evident freedom from the paroxysm.

I was not advised it could be continued in safety all night, or even day or night, and at the expiration of 15 minutes extinguished the lamp. The children had been whooping 20 times a day. One of them did not even cough for 12 hours, the other for 36.

Learning that the vaporization could be continued day and night with more rapid benefit, I applied it for five nights in their sleeping-room. The spasms ceased and they speedily recovered. At that time an epidemic of whooping cough was raging in my vicinity. I advised my neighbors of this apparatus. Many of them were used, and with the best results.

I believe the vaporizers and cresolene are now to be obtained from druggists. I am confident it will be found equally efficient in all throat and lung diseases. Inhalation is the true mode of treatment. The apparatus is nearly perfect as an agent for deodorizing, disinfecting and perfuming not only the sick room but an entire house. It deserves an extended trial. RANOELEY.

**PEPSINE FOR TAPÉWORM.**—The tapeworm is able to live in the stomach because of its ability to resist the digestive action of the fluids normal to the stomach. In a stronger peptic solution the live worm succumbs and is digested like any other flesh. Accordingly a French physician treated with strong doses of pepsine a child who had passed segments of a large tapeworm. About 45 grains of pepsine were administered daily for five days. The child experienced no harm and showed no special symptoms. Then a proper dose of sulphate of peltierine with castor oil was given, and the discharges showed no signs of the worm. Subsequent experiments with vegetable pepsine—papaine—which is much more active, are said to have given very promising results. One child passed fragments of tapeworm ten inches in length, softened and partially digested.

**REMEDY FOR ACID BURNS.**—Since vitriol-throwing has become a common offense, it may be well to point out that in a case which occurred during a chemical lecture, described in the *Bulletin de Therapeutique*, in which two students were seriously injured in the face by the explosion of a flask containing boiling sulphuric acid, the intense suffering at first experienced ceased entirely about a quarter of an hour after the application of a soft paste of calcined magnesia and water in a layer about two millimeters in thickness. M. Alande states that the magnesia requires to be renewed in 24 hours, but that patients, after recovery, retain no marks of the accident.

**TATTOO MARKS MADE USEFUL.**—"Why is it," asks Dr. Le Comte, who is physician to a regiment of dragoons, "Why is it that each number of soldiers die upon the battle field?" And then he replies, confidently: "Simply because of the difficulty which arises in regard to arresting hemorrhages." The compression of an artery being the best mode of stopping profuse bleeding, Dr. Le Comte proposes to teach each soldier first where these vessels are situated, so that he may assist himself while waiting for the surgeon. Therefore, he tattoos an image of some kind upon every portion of the soldier's body where there is an artery.

## TABLE OF CONTENTS.

**EDITORIALS.**—Mining Statistics of Counties; The Pacific Copper Smelter; Industrial Progress, 385. Sonora, Mexico, 390. Passing Events; Our Map; Our Arizona Edition; Our Home Industries, 392. The Brush Electric Light, 393-94-95. Color of minerals; Painted Rocks; Miners Rights to surface Ground, 396. Clay Deposits of California; The Aborigines of Arizona, 397. Extravagant Prices for Prospects; Arizona's Future, 398. History and Antiquities of Arizona; Early Towns and Missions of Arizona; The Colorado and its Great Canyons; Rivers in Arizona; Arizona Fauna and Flora; Sierra Mitas, 404. A Mining Romance; Magnetic Separation of Ore; The Truth about Arizona; Columbus District, Nevada, 406. Two Native; Sweepstake Thoroughbred Wagon, 410. The Lone Peaks, Arizona; Region of the Thousand Wells, 412. Notices of Recent Patent, 416.

**ILLUSTRATIONS.**—The Pacific Copper Smelter, 385. Map of Sonora, Mexico, and Surrounding Country, 390. The Brush Dynamo-Electric Machines, 393-94-95. The Painted Rocks of Arizona, 396. The Aborigines of Arizona, 397. Map of Arizona, 401-02. A Native of Arizona; A Native of California; A Thoroughbred Wagon of the Sweepstake Plow Co., 410. Lone Peaks, Between Ehrenberg and Prescott, Arizona; Region of the Thousand Wells, Echo Cliff, Arizona, 412.

**CORRESPONDENCE.**—Fresno County Notes; Anador County Mines; Mount Baldy District Utah; Volatilization of Gold; Mines at Plymouth, 386. Botany in Arizona, 397. Idaho Territory and its Resources; Geological and Botanical Collections, 398. Arizona's Agriculture, 400. The Wood River Mines, 406. Contributions to the Geology of California, 392.

**MECHANICAL PROGRESS.**—Mode of Construction and Operation of the Electric Railway; Durability of Building Materials Under Heat; Setting Car Wheels; Pressure, Instead of Hammering, for Shaping Iron; Effect of Impurities on Copper; Pulverized Fuel; Experiments with Steel wire, 387.

**SCIENTIFIC PROGRESS.**—Polarization of Sound; Working and Molding Iridium; A Stereographic Photo; Impermeable Paper; Effect of the Timber Line on High Mountains; Effect of Pressure in Carbonizing Wood; Acting Zinc; An Electric Tricycle; Distilling Alcohol by Ice; The Uncertain Character of Ozone; Length of Jupiter's Day; A New Experiment on Magnetic Attraction, 387.

**MINING STOCK MARKET.**—Sales at the S. F. Francisco Stock Board; Notices of Assessments, Meetings and Dividends, 388.

**MINING SUMMARY.**—From the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon and Utah, 388-9.

**USEFUL INFORMATION.**—Preservation of India Rubber Under Water; Testing Lubricants; Bleaching Ivory; Improved Canning Boxes; Syrup that Will not Ferment; Enormous Photographs; Removal of Fuses Oil and Clarification of Liquors; Imitation Leather; Harvesting Header; To Remove Oil that has Dried Upon Iron or Brass; To Polish Brass, 391.

**GOOD HEALTH.**—Cure for Whooping Cough; Peppine for Tapeworm; Remedy for Acid Burns; Tattoo Marks Made Useful, 391.

**MISCELLANEOUS.**—Special Exhibitions—Their Great Value and Importance, 390. Arizona's Climate; Saddle Mountain Coal Fields; Averill Mixed Paint; Silver Ore on the Trees, 391. Color of Minerals; A Cheap Pump for Mines; Miners' Rights to Surface Ground; Jumping Claims; Arizona's Wealth; Saving Sulphurates; Tell us the News; The John Day Country; Dan Glen; 396. Clay Deposits of California, 397. Extravagant Prices for Prospects; Arizona's Future; Possibilities of Cast Iron; The Corrosion of Iron and Steel, 398. To Regulate Chloridizing Roasting of Ore; Simulas and Durango; Copper in Arizona, 400. A Mining Romance; Magnetic Separation of Ore; The Truth about Arizona; Columbus District, Nevada; One for Roasting Ore; Mile Mines and the Cause, 406. The Old River Beds of the Sierra Nevada of California; Chlorination Tailings, 409. Industrial School of Miners and Mechanics, 410. The Magnetic Needle and Mining Plans; The Hydraulic Mining Injunction, 412. Foreign Industrial Notes, 388.

## Business Announcements.

Giant Powder—Bandmann, Nelson & Co., S. F.  
 Vaseline—Sweepstake Plow Co., San Leandro, Cal.  
 Mill and Mining Machinery—Bankin, Gray & Co., S. F.  
 Sugar and Syrup—California Sugar Refinery, S. F.  
 Stamp Mill—F. A. Huntington, S. F.  
 Lubricating Oil—A. C. Dietz, S. F.  
 Leather Belting—H. A. Cook, S. F.  
 Machinery—Linfirth, Rice & Co., S. F.  
 Soap—Standard Soap Co., S. F.  
 Pacific Business College, S. F.  
 Champagne—Harsanyi, S. F.  
 Brush Light—California Electric Light Co., S. F.  
 Drills—Richmann Drill Co., S. F.  
 Blasting Powder—Excelsior Powder Co., S. F.  
 Insurance—W. Lane Bookler, S. F.  
 Dividend Notice—Northern Belle M. & M. Co.  
 Extra Dividend Notice—Northern Belle M. & M. Co.  
 Dividend Notice—Eureka M. Co.

Removal—Caledonia G. M. Co.  
 Removal—Clara Con. M. Co.  
 Removal—Mammoth M. Co.  
 Machinery Works—W. H. Ohmen, S. F.  
 Furnace—O'Hara Furnace Co., S. F.  
 Iron Pipe—Richards & Snow, S. F.  
 Paint—Averill Paint Co., S. F.  
 Leather Belting—H. Royer, S. F.

 Metallurgist—C. H. Aaron, S. F.  
 Fulton Iron Works—Hinkley, Spiers & Hayes, S. F.  
 Life Saving Respiator—Seth Marshall, Jr., S. F.  
 Meeting Notice—Warren Powder Co., S. F.  
 Boilers—J. V. Hall, S. F.

## Passing Events.

The "passing event" which interests us most just at this moment is the publication of this 36-page edition of the Press, and we trust it will interest our readers sufficiently to repay us our labor in preparing it. Space is so limited with us this week, every line being taken up with important matter, that under this heading we can have little to say. The Rodgers Arctic search expedition has departed on its mission; American horses have won victories in Europe; and—other items will be found of interest to all. A big miners' meeting will be held on the 24th of this month, at Nevada City, in behalf of the hydraulic mining interest. They will set before the people their side of the case.

## Our Arizona Edition.

This edition of the MINING AND SCIENTIFIC PRESS comprises 36 pages, including a fine map of Arizona and numerous illustrations. We have compiled a large amount of information about the Territory of Arizona which will be found in these pages. As to any extended remarks about the mining regions we have given all that from time to time in our columns and so refrain from it on this occasion. We confess, however, that limit of space has crowded out some matter already prepared.

Our map, to which we refer under another head, shows all the districts, rivers, cities, mines, railroads, etc. Our illustrations relate mainly to Arizona, though we have given considerable space to the subject of the electric light as applied to mines, and have also an engraving of a copper smelting furnace, an appliance now very much used in Arizona and elsewhere. The map of Sonora will be appreciated at this time, when so much attention is turned in that direction.

We trust our readers will appreciate our efforts to furnish them a good paper. We print several thousand extra copies of this issue of the Press, which will be scattered throughout the country. Though we have printed a great deal about Arizona, the usual variety will be found in our columns.

## Our Map.

The map of Arizona which we publish in this number of the Press was engraved from Kieckhefer's large map made last year. We have, however, made many corrections and additions. The line of the Southern Pacific railroad is now correct, Col. Gray, the Chief Engineer of the road, having placed it properly on the map for us. The stations on the Southern Pacific are all properly located. The line of the Atlantic and Pacific is located on this map. The route of the Atchison, Topeka and Santa Fe was incorrectly placed on the old map, but the correction has been made on this one. We are unable of course to locate the line of the branch road of the Southern Pacific to Point Isabel, as the surveyors are now at work running lines over two routes and nothing definite has been decided upon.

As to mines, a great many districts have been formed since the original map from which this was taken, was made. We have, however, added those new districts' names on the map. In addition, therefore, to the list of names on the side of the map, the names of many other districts will be found engraved in their proper places. We have endeavored to be as correct as possible in this, though a few errors may have crept in.

The map will be found useful for reference by all mining men, since the districts, mines, rivers, roads, etc., are all shown. Taken in connection with the descriptive matter found in this number of the Press, it will give a great deal of information about the thriving and growing Territory of Arizona.

## The Mining Bureau.

The State Mining Bureau, at present at 313 Pine street, will shortly be removed to new quarters, as the building is to be torn down to give place to a fine structure to be built by James G. Fair. Mr. Hanks has been looking for suitable rooms for some weeks, and will probably locate at the Grand Opera House on Mission street, near Third. There is a fine large room there, originally intended for an art gallery, and surrounding it are a number of smaller rooms. Mr. Hanks has not decided yet, but these are the only available quarters presenting themselves now.

## Contributions to the Geology of California.

### New Series.

No. 2. Section from Merced to Coulterville and Big Oak Flat.

H. G. HANKS, STATE MINERALOGIST: From Merced station upon the Southern Pacific railroad the line of section described in this contribution extends in a northeasterly direction nearly transverse to the line of strike of some of the most interesting gold-bearing rocks of the Sierra Nevada.

Merced is situated upon the alluvial plains of the San Joaquin. The level and clay soil, noted for its fertility and adaptation to cereals, extends without change to the six-mile house, where gravel begins to show itself and the soil is poorer and more arid. Another six miles over a gently rolling gravelly plain brings us to the banks of the Merced. Crossing by ferry to the right bank, we travel along the broad and rich bottom lands to Snellings and Merced falls, passing plantations of Indian corn and cotton.

At Merced falls, the first outcrop of the older rocks is observed. It is a hard bar of compact black clay slate, like roofing slate, very uniform in texture, in broad flat plates, standing vertically on edge, trending in remarkably straight lines northwest and southeast. This hard outcrop forms a natural dam, upon which the rapidly flowing water of the Merced has made but little impression. There is a fine water power at all seasons, which is partially utilized by a woolen mill. We here leave the river and ascend the hills to the northeast. The black slates carry numerous veins of white quartz which have not been much prospected.

A few miles beyond the falls, the surface rises rapidly, and the slates give way to harder rocks. These are light bluish-green in color, weathering in places almost white. They are evidently of sedimentary origin, though much altered and changed from their original condition. They form the outlying belt of a series of heavily bedded conglomerates, sandstones and shales, which, being harder and less susceptible to erosion than the slates, form the high hills and ridges. These elevations trend northwest and southeast, and are probably the northwestern extension of the Mount Oso range, which traverses a large portion of Mariposa county, and forms the western wall of Bear valley, on the Mariposa estate.

The heavy and bold outcrops of the massive conglomerates composing this range are not readily recognized as conglomerates. Their composite character is obscure. Generally it is scarcely possible to recognize that the rock is made up of rounded boulder-like masses. The boulders which form these rocks are so much compressed, welded, and united in one apparently homogeneous plasma that the dividing lines and contact surfaces are obliterated, and cannot be seen except upon surfaces that have been weathered and sometimes upon broad surfaces of fracture. Occasionally, where the metamorphic action has not been as strong as in other places, the original forms of the boulders can be made out, and the masses stand out from the general surface. In decomposing, these old conglomerates reveal their origin by yielding a vast amount of hard boulder-like masses, elongated and lens-shaped spheroids, which are utilized for fencing. These rocks are generally known and described as "greenstone," the color being light bluish green, and the mineral composition of the boulders being like the greenstones. They offer a very interesting subject of study to the lithologist and to the student of dynamical geology. They border on each side the belts of slates in which most of the quartz veins are found and have, next to the granites, best withstood the denuding and wearing forces of the elements, and thus have to a great extent determined the topography of the piedmont region of the Sierra Nevada.

Upon the line of the section herein described, such conglomerates occur in a number of parallel outcrops with slaty rocks between and belts of sandstone, the exact succession of which cannot be determined without painstaking investigation. The whole series occupies a breadth of about 20 miles between the slates of Merced falls and the cinnabar slates of Coulterville valley. It includes at least two bodies of well-defined pebbly conglomerate, in which the pebbles are small—not much larger than beans. These conglomerate beds lie parallel with beds of argillaceous slate, and clearly demonstrate a succession of deposits formed in alternating deep and shallow waters. Approaching Coulterville we descend the hills of greenstone conglomerate and pass suddenly upon the black slates of the valley. They greatly resemble the outcrops at Merced falls, and probably are a repetition of that series. Here, however, they are especially interesting, as the matrix of the two chief lines of gold-bearing veins in California, the so-called "mother lode" of the State. In this valley, as also upon the Mariposa and farther north, there are two nearly parallel lodes of great size, the croppings of which are so bold and prominent crowning the hills as to be visible for miles.

The western lode rises between walls of black slate, and carries films and sheets of the slate in its mass, giving to it a more or less stratified form and a striped appearance when seen in cross sections or as it stands in the mines. Such quartz is technically known as ribbon quartz, and is a great favorite with quartz miners. In the mother lode proper a short distance farther

east, the quartz is more massive and solid, and is in close proximity to a belt of serpentine, and for a great part of its course follows and penetrates a stratum of magnesian rock, referable to ankerite and magnesite. It is characterized by rusty outcrops and an abundance of a foliated, bright green mineral to which the name "Mariposita" has been given. It appears to owe its green color to chromium and iron rather than to copper or nickel. The quartz penetrates this magnesian rock so thoroughly as to form in many places a complete network of veins branching off from the chief body.

Beyond the veins and magnesian belt the slates are seen again for a short distance and are succeeded by greenstone conglomerates.

Beyond these, on the road to Big Oak Flat, there is a heavy body of syenites forming a hilly region traversed by the road for ten miles north and east to Priest's, on the Yosemite road. From Priest's, westward, there is a region of massive, hard black slates, which appear to belong to the series of formations in which the limestone belt of Sonora and the Hita group of veins occur. I regard them as older than the mother lode series of slates and believe that they belong to the period of the carboniferous, the reasons in part for this belief being their stratigraphical relations to other formations and the abundance of carbonaceous matter which they contain.

The mother lode slates have been shown to correspond in age to the Jurassic period. I am inclined to refer the greenstone conglomerates series to the trias.

The whole series of formations embraced in the section give satisfactory evidences of extensive plication and subsequent erosion. The dips are generally eastward and at a high angle.

WM. P. BLAKE.

## Our Home Industries.

Machinery Oils from California Products.

Among the important home industries in our midst which illustrate California's advancement as a manufacturing State, are those of the oil and paint, and oil business, since we are now quite independent of Eastern manufacturers in this branch. One of our leading houses in this line, which has distinguished itself for its successful encouragement of home production in this line of business, is the well-known firm of A. C. Dietz & Co. This house, established some 30 years since, is one of the oldest in the State. It was first located on Montgomery street, then the principal business street of the city. At that time, in addition to a general business in paints and oils, the manufacture of camphana burning fluid, largely consumed in those days, was begun by this firm, and this supply was continued till its use was superseded by kerosene. Since that date, owing to the changes which have taken place in the location of the wholesale trade, and the steady expansion of their business, Messrs. A. C. Dietz & Co. have made several removals, on each occasion to large and more commodious quarters. The change recently made by this house, from No. 224 to No. 9 Front street, is well worthy of mention. The edifice is a substantial one of brick and iron, three stories high. The basement is used for the storage of various kinds of oils, of which a large stock is carried in tanks, hogheads and barrels. Access from this part of the building to the stories above is had by an elevator.

The first, or street floor, used for the principal sales-room and for offices, is excellently arranged, and includes, among other conveniences, a telephone for the use of the firm and its customers. On the right of the entrance from the street, is a convenient office for the display of samples, for shipping and other purposes. The remainder of this floor, except that portion appropriated for counting-rooms, is utilized for the display and storage of the numerous brands and qualities of oils, paints, varnishes, glues, brushes and other articles in the line of goods manufactured and dealt in by the house. The story above, the second, contains a large stock of dry paints, zincs, shellacs, lanterns of various kinds, beadlike chandeliers, lamps, wicks and a full assortment of kerosene fixtures of all sorts. The upper floor is used for the storage and shipment of lamps of all kinds, lanterns of various patterns, including those for ship's use, which are a specialty with Messrs. A. C. Dietz & Co., and of which a large stock is carried, glass chimneys, cotton waste, etc.

We have heretofore mentioned that Messrs. A. C. Dietz & Co. have long been identified with home manufactures. This firm recently established a factory at Berkeley, known as the "Berkeley Lubricating Oil Company." At this refinery they make all the machinery oils from California products. The crude oils come from Vantura, where they are produced in large quantities. The oils manufactured by them embrace cylinder, leather and all kinds of lubricants suitable for mining machinery, railroad use, etc., as well as illuminating oils, which are said to be of superior quality. The latter include the Mineral Solar oil, a high fire test oil of 300°, for use on steamers and elsewhere, and the well-known Headlight 175° test oil for locomotive and mill use. The firm also supply the Prizal Medal oil, for ordinary lighting purposes. The Berkeley Lubricating company is now turning out some 100 barrels of lubricating and manufacturing oils daily, and it is anticipated that the supply from this source will soon be sufficient for all local requirements.

## The Brush Electric Light.

It is now some six years since Mr. Charles F. Brush, of Cleveland, Ohio, produced the now famous system of electric lighting named after this brilliant inventor. During this period, the Brush electric light has gained the foremost rank, and is to-day pre-eminently the most perfect and widely used system of electric lighting in the world, over ninety per cent. of the total lights in use being of this pattern.

The California Electric Light Co., No. 119

mile in diameter, as light at the farthest point as it would be with a gas lamp of usual street size every hundred feet. The trial showed this requirement to be more than fulfilled, as it was light enough at much more than that distance to tell the time on a watch, or read coarse print. Over 10,000 people witnessed the test.

This is the plan that has been proposed for the lighting of the Capitol and its surroundings at Washington. It is proposed to place upon the dome of the Capitol and upon six towers surrounding it, at a distance of 1,000 ft. from it, no less than 450 electric lights, each of 6,000 candle power, or a total light of 2,700,000 candle power, equal to 200,000 4-ft. gas burners.

facture their own carbons, making the whole installation still more peculiar to themselves.

The Brush machine, a general view of which is given in Fig. 1, possesses some points of resemblance to the dynamo-electric machines of Gramme and of Wallace-Farmer, as well as to the magneto-electric machines of M. de Meritens, while at the same time its principle of construction differs from that of all others, and confers upon it at once its special excellence and its originality.

Its point of resemblance to M. Gramme's machine consists in the fact that its armature is of annular shape, a form of construction first adapted to the purpose by M. Gramme some 13 years

ago, iron which from the enlarged section are brought into as close proximity to the poles of the field magnets as are the outsides of the coils themselves. It is this difference from the Gramme ring which constitutes the similarity between the Brush armature and that of M. de Meritens, but the Brush machine differs in all other essential respects from the latter machine in the disposition of its coils, in its method of connection, in the method and arrangement of the magnetic field, and in the continuous nature of its current.

The Brush machine, however, differs altogether from the Gramme generator in the disposition of its field magnets and the relative positions of

Fig. 6.

## THE BRUSH DYNAMO-ELECTRIC MACHINE.

O'Farrell street, San Francisco, is the fortunate possessor of the Brush patents for the Pacific Coast. We are glad to note its introduction into hydraulic mines, mills, smelting works, etc. One hydraulic miner says: "It enables us to operate the mine at night practically as well as day." And, after two years' constant use, says: "It continues to give uniform and satisfactory results." Thus showing its durability. But there seems to be a larger and more important field for the electric light, viz: city lighting from an elevation, known as the tower system. We notice that the Brush Co. is successfully lighting Wabash, Indiana; Akron, Ohio, and other cities in the East, in this way, and are pleased to know that arrangements are being made to light several cities on this Coast by the tower system. The Boston Daily Advertiser says, regarding Wabash, Indiana:

The contract was that the lights (four lights elevated 200 ft.), should illuminate a circle one

The effect of such an enormous massing of light at such a distance above the ground and surrounding buildings would produce a surprising effect, and within a considerable area would, no doubt, be practically equal to daylight. If this plan is carried out the Brush light will be used. This subject will be brought to the attention of the next session of Congress.

We take the following complete scientific description of the Brush system from the London *Engineering*, and will at a later date publish a description of the system written by Mr. Brush himself:

The Brush, like the Siemens system, includes both generator and regulator peculiar to itself, and may, therefore, be looked upon as complete in itself, differing in that respect from all those so-called systems which are represented by either a particular form of machine or a special arrangement of lamp, and like the proprietors of the Siemens system, the Brush company manu-

ago. The Brush armature differs, however, from the Gramme ring in the arrangement and disposition of the helices of wire with which it is wound, as well as in the way in which the several coils are connected with one another. In the Gramme armature the coils are wound contiguously to one another, so as entirely to envelop the iron core, hiding it completely from view, and they are permanently connected to one another in consecutive series. In the Brush armature the diametrically opposite hobbins are alone permanently connected together, and a current generated in one pair of hobbins does not necessarily traverse all the others, and, in fact, never does, as will be pointed out in the course of this notice. Again, the individual coils are separated from one another by a considerable sector of the iron ring, which is of larger sectional area between the coils (see Fig. 2), so that in the revolution of the armature within the magnetic field, the coils alternate with masses of

the revolving helices and the magnetic field. In the disposition of its magnets the Brush machine more nearly resembles the Wallace-Farmer apparatus, but their form is entirely different, and the armature of the Wallace-Farmer bears no sort of resemblance to the Brush ring, its coils being more allied to those of M. Loutin's machine than to any other of the characteristic generators. Having thus pointed out the position occupied by the Brush machine with respect to other typical generators, showing wherein it approaches and wherein it departs from the machines of other systems, we will proceed to describe its construction.

The most characteristic feature of the Brush machine lies in the form and construction of its armature, which consists of a cast iron ring, the cross section of which is generally rectangular, but in the direction of its circumference it is alternately wide and narrow, as shown in the sketch, Fig. 2, which represents a portion of the

iron armature ring and explains its construction better than can be given by description. On reference to this figure it will be seen that the ring is divided up into as many sectors as there are bobbins to be wound, by a number of rectangular depressions or grooves; in these the coils of insulated copper wire are wound until the groove is filled up and the flat converging recesses become flush with the face of the intermediate thicker portions or pole pieces by which they are separated from one another. Fig. 3 is a cross section of one side of the ring taken through one of these portions, and it will be observed on reference to both figures that the intermediate thicker portions of the ring are grooved out by a series of deep concentric grooves, the object of which is partly to reduce the mass and lessen the weight of the revolving armature, partly for the purpose of ventilating the ring and thus carrying away a portion of the heat generated by the working of the machine, but chiefly for the localization and isolation of local currents generated by induction in the iron, and which would tend not only to reduce the efficiency of the machine by diminishing the magnetic capacity of the armature, but also to produce a heating of the ring, and, therefore, of the coils, whereby a portion of the current would be lost through their resistance being increased. For a similar reason the periphery of the ring is grooved out deeply so as almost to sever the ring; by this means all cross currents are effectually cut off and induction currents are compelled to flow in directions which are not detrimental to the efficiency of the machine. This again increases the area of radiating or cooling surface, and consequently helps to prevent the armature becoming overheated.

In what is called the 16-light machine, which may be regarded as the normal size of the Brush generator, the armature ring is 20 inches in diameter, and it is wound with eight radial coils of cotton-covered copper wire, of No. 14 B. W. G., whose middle planes radiate from the axis or rotation, being distributed round the ring at equal angular distances apart of 45 degrees. Each coil contains about 900 ft. of wire weighing about 20 lbs., and is wound in the rectangular grooves or spaces shown in Fig. 2, filling up the space completely, so that the vertical faces of all the coils are flush with the vertical faces of the thicker portions of the iron ring. Fig. 4 is a sketch of the armature ring with all its coils wound, which must be looked upon rather as an explanatory diagram than as an illustration of the proportions of this part of the apparatus. The two sides of each groove, and therefore of each coil of wires, are parallel to the center line or radial plane of the coil, and by the adoption of that form of bobbin one of the practical difficulties in the winding of annular armatures of the ordinary form is avoided. All the coils are, like those in the Gramme machine, wound in the same direction.

Fig. 5 is a diagram illustrative not only of the distribution of the coils around the rings, but of the method by which the connections are made. The inner end of each of the coils is connected by a wire to the inner end of the corresponding coil at the opposite end of the same diameter of the ring; and the other ends of all the coils are brought through the shaft of the machine, and are connected to corresponding portions of the commutator, where the currents are collected by suitably placed copper plates or brushes. Referring to the diagram, it will be seen that the inner end,  $a^1$ , of the coil, 1, is connected to  $a^5$ , which is the inner end of the coil, 5;  $a^2$  is connected to  $a^6$ ,  $a^3$  to  $a^7$ , and so on round the ring, and the outer ends,  $b^1$ ,  $b^2$ ,  $b^3$ , etc., are all connected to the commutator by conducting wires insulated from one another. The two free ends of each pair of diametrically opposed coils are, after passing through the shaft of the machine, attached respectively to two diametrically opposite segments of the same commutator, which segments are insulated from one another and from any other pairs of coils. The commutator, which is attached to and rotates with the driving shaft of the machine, consists of a set of separated copper rings or flat cylinders, of which there are as many on the shaft as there are pairs of coils on the armature, and each of these cylinders consists of two segments insulated from one another, on one side of the shaft, by a small air space about one-eighth of an inch wide, and on the other by a piece of copper separated from the segments by two smaller air spaces. The arrangement is shown in Fig. 6, in which  $a$  and  $b$  are the two segments connected respectively to corresponding coils on opposite sides of the armature, and attached by an insulating material to the shaft;  $c$  is the copper insulating piece, the object of which is to separate either of the flat copper brushes or collectors, which press upon the periphery of the commutator, from either of the segments during the interval occupied by one pair of coils passing the vertical, or in other words through the neutral portion of the magnetic field; this occurs twice in each revolution of the armature, and therefore of the commutator. At the time when any pair of bobbins is in this way cut out of the general circuit, their own circuit is open, so that no current can circulate or be induced in them. By this most ingenious arrangement each pair of coils has in succession in each revolution a period of rest equal to one-quarter of a revolution, and has a current passing through it for only 75% of the time the machine is running; to it is, in great measure, due the very small development of heat in the working of the Brush machine, and it presents also another important element of efficiency to the machine, namely, that each pair of bobbins as it passes the neutral portion of the magnetic field, and is therefore incapable of doing work and contributing electromotive force to the general current, is itself cut out of the cir-

cuit, and thus two causes operating against the efficiency of the machine are eliminated; the first is one common to most armatures which have, like that in the Gramme machine, a permanently closed circuit, namely, that the currents generated in the bobbins have two routes open to them; the one through the conductors and commutators to the brushes, and the other through the idle bobbins, and thus by a species of short circuiting, robbing the external circuit of some of its current. The other cause of inefficiency which is avoided in the Brush machine is the reduction of its internal resistance by an amount equal to the resistance of two of the bobbins, for just as a certain amount of resistance is an item of efficiency when belonging to coils which are doing work and contributing electromotive force to the general current, so does it become an element of inefficiency when belonging to coils which are idle, for in that case it diminishes the current supplied by the active coils while at the same time contributing no current of its own in compensation. By the arrangement of commutator referred to above, Mr. Brush has, therefore, got rid of two considerable drawbacks to the efficiency of the machine.

What is, however, one of the important features of the Brush machine is the arrangement of the magnets by which the magnetic field is produced, and by which the armature coils are, during their revolution, almost continually passing through a very intense magnetic field. Upon reference to Fig. 1, it will be seen that the armature ring is closely embraced on each side by the large horizontal electro-magnets whose poles are expanded so as to be presented to three of the armature coils on each side, leaving one pair of coils free from their direct influence, and this is the pair which is passing through the neutral region of the magnetic field. For the sake of illustration, the disposition of the magnets toward the armature and toward one another may be described as two horseshoe electro-magnets opposite one another in a horizontal position, their similar poles being presented toward one another, and having a small space between them

Fig. 7.

in which rotates the armature ring. This space in the machines we are describing is, however, so nearly equal to the thickness of the armature that there is hardly any clearance between them, the high class workmanship of the apparatus allowing such close working with perfect safety.

The methods of exciting the field magnets in dynamo-electric machines are very different under different systems. In the early Gramme machines a separate armature was set apart for producing the current which, by traversing the magnet coils, produced the magnetic field between their poles, and the current from this armature had no other work to do, the useful or external current being taken direct from one or more other armature rings attached to the same shaft. The excitement of the magnets in one machine by a current supplied from another or from a special armature of the same machine was first suggested and employed by Mr. Wilde, of Manchester, whose name, and that of Mr. Holmes, must ever be associated with the early history of the production of electricity by mechanical means. In the latter form of the Gramme machine, as well as in the ordinary Siemens machine, the whole of the current from the armature is transmitted through the magnet coils, they forming, with respect to the armature, a portion of the external circuit. In other systems, such as the Lontin, the Jablockhoff-Gramme, the Siemens alternating current machine, and in extensive installations of the Siemens machine, the field magnets of one or more generators are excited by the current from a special machine which has no other work to do; and in a special form of the Siemens machine the magnet coils form a shunt circuit to the armature, by which arrangement the machine acts to a great extent as its own regulator.

The system adopted in the Brush machine is, however, different to all to which we have just referred, while it has certain points of similarity to all. In the Brush machine the current contributed by each pair of bobbins on the armature is switched by the commutators alternately through the magnet coils and through the external circuit, so that each bobbin in its revolution "feeds" alternately the magnets and the lamps; and at any one position of the armature alternate bobbins are feeding the magnets while the rest are sending their currents to the "line," while at the next eighth part of a revolution, those which were feeding the line are switched on to the magnets, and vice versa. Fig. 7 is a diagram illustrating the connection between the armature bobbins and the magnet coils at the time when the commutators are placing them in the same circuit. Referring to this diagram,  $m$  and  $m^1$ , are the two magnets having their similar poles presented toward one another on opposite sides of the armature coils,  $a$  and  $a^1$ . Thus the coil,  $a$ , is under the influence of a mag-

netic field produced by the two north poles,  $n$  and  $n^1$ , while at the same time its corresponding bobbin,  $a^1$ , is under the influence of the two south poles,  $s$  and  $s^1$ ; a current is therefore induced in the pair of bobbins,  $a$  and  $a^1$ , which is transmitted by wires passing through the shaft,  $s$ , to the commutator,  $c^1$  and  $c^2$ , whence it is collected by the brushes,  $b^1$  and  $b^2$ , and by them transmitted to the magnet coils, which are all collected together in series, and at the same time the other portions of the commutators (which are in connection with the other working armature bobbins) are in contact with the brushes,  $b^3$  and  $b^4$ , by which they are placed into the external circuit of the machine.

One of the most original and interesting features of the Brush machine is the commutating apparatus, which, by the simplest of mechanical means, collects and distributes the currents from the active armature coils, sending them into the magnet helices or into the "line," according to their position in the magnetic field, and cutting out of circuit the armature coils one by one as they pass through the neutral region between the poles. The whole commutating apparatus is fairly represented on the extreme right of the general view of the machine (Fig. 1), and consists of two pair of rings of the form shown in Fig. 6, attached to and revolving with the main shaft, and, therefore, their position is fixed with respect to the revolving armature of the machine. On to the cylindrical circumferences of these rings are pressed two pairs of copper collecting brushes, which rub tangentially against the commutator rings, one pair pressing above and the other pair pressing below, a line forming the points of contact being a diameter of the ring. The copper "brushes," as they are called, are flat strips of elastic copper about two inches wide, cut at the ends, which press against the rings into eight tongues, so as somewhat to resemble a grainer's comb, and each comb or brush is wide enough to cover or be in contact with two armature rings, and in this way, although two of the coils are insulated twice in each revolution, the main circuit is never inter-

rupted. The disposition of the brushes with respect to the commutators will clearly be understood by comparing Fig. 1 with Fig. 7.

For the sake of adjusting the brushes so as to make contact with the commutators at the most effective angular position with respect to the magnetic field, they are mounted to the opposite ends of two rocking levers, which are capable of oscillating on the driving shaft, and can be fixed in any desired position by means of a set-screw, which clamps a stout wire rising from the base of the machine. The currents are conveyed from the brushes by wide strips of thin sheet copper, shown in the general view, and in order to allow for the variable distance of the free ends of the brushes from the base of the machine, they are made undulating or wavy, doubling up as the distance is shortened and stretching out when it is increased.

The average total resistance of the 16-light machine, as now constructed, is about 11 ohms, to which the eight coils of the armature contribute about five ohms, that is 0.625 ohm each, and the magnet coils about six ohms, or 1.5 ohm for each helix—the resistance of the connections, conductors, contacts, etc., within the machine being inconsiderable.

#### The Lamps.

The regulating electric lamps designed by Mr. Brush, are quite as much an element of the remarkable success of his system of electric lighting as are the machines themselves, and while their performance is surpassed by no other regulator, and although they contain special contrivances to enable them to maintain a steady arc when burning 16 or more together in a single circuit, they are probably the simplest in construction of arc regulators, involving no clock-work or complicated feeding mechanism, or indeed anything that is liable to become deranged. They can be constructed to burn continuously for 8, 16, 24, or indeed for any desired number of hours, and the mere hanging of a lamp in its place puts it thereby into the circuit of the other lamps of the series, and with the machine; while, on the other hand, the extinction of one or more lamps, or indeed their removal altogether, does not affect the others except (if the machine be driven at the same speed) to make them brighter; but by driving the engine slower and therefore using less steam, the same initial degree of illumination can be maintained in each of, say 14 lamps, as if all the 16 were in operation. The great simplicity of the Brush lamp consists in the fact that the feed is actuated by gravity alone, while it is controlled solely by the influence upon a bar of iron of a magnetic field, the intensity of which varies with the strength of the electric current passing through the lamp circuit. The general external appearance of three forms of Brush regulators

is shown on the opposite page in Figs. 8, 9, and 10; the first representing the single carbon, or 8-hour lamp, the second, the double carbon or 16-hour lamp, with its glass globe removed; and the last is a sketch of a more ornate form of the double carbon lamp, the controlling apparatus being inclosed in a nickel-plated case. In all these lamps, which are designed for general illumination, the lower carbons are fixed, and as they burn away the upper carbons follow them, so the arc gradually descends, but for certain special installations, such as lighthouses or for purposes of projection, a focus-keeping arrangement has to be applied.

Like most of the modern electric lamps, the upper carbon descends by its own weight until it touches the lower carbon, and the circuit is thereby completed; the effect of this in the lamps we are describing, is to cause a soft iron plunger to be drawn to a more or less extent within a hollow coil, or sucking magnet, as it is sometimes expressively called; and through the intervention of a lever and a most ingenious annular clutch surrounding the rod of the upper carbon like a washer, the upper carbon is lifted away from the lower, and the arc is established. As the carbons burn away, the arc has a tendency to become longer, and its resistance to increase and this by diminishing the strength of the current, diminishes the supporting power of the magnetic helix, allowing its plunger to descend, and, in so doing, to lower the carbon and shorten the arc until the proper strength of the current is restored, when the rising of the plunger once more holds the carbon in position. In the above very general description we have advisedly spoken of the influences as *tending* to produce the effects, for, as a matter of fact, so sensitive is the controlling apparatus to the smallest variation of current, that there is practically no reciprocating action, such as the above description might suggest, but the normal condition of the upper rod is to be slowly sliding through the clamp as the carbons become shorter, but if by any chance the rod slides a little too far, the clutch immediately raises it again and the carbons are adjusted to their proper distance.

All who are familiar with the great difficulties which hitherto have appeared to be almost inseparable from the burning of several arc lights in a single circuit, will know that a number of regulators constructed from the above very general and incomplete description, and with no other controlling contrivance, would be totally incapable of burning uniformly in a single circuit, and it is the extremely simple and ingenious method by which each lamp controls itself independently of the action of all the others in the circuit, and yet independently on the strength of the current in that circuit, that constitutes at once the great originality and the great perfection of the Brush regulator.

At first sight the problem might appear to be insoluble, but Mr. Brush has solved it in the following manner. Each of the bobbins of the controlling magnet is wound with two distinct coils of wire, the first consisting of a number of turns of thick wire, through which the current is transmitted to the arc, and the second of a much larger number of convolutions of fine wire which form a secondary or shunt circuit between the terminals of the lamp, the connections being made in such a way that the electric current shall pass through it in a direction opposite to that in the primary of thick wire circuit, forming a shunt circuit of high resistance through the lamp, which, being always closed, is independent of the arc. It will readily be understood that, as the current flows in opposite directions around the magnet, the influence of the fine wire circuit will be to neutralize or weaken the attractive influence of the thicker helix, but the number of the convolutions of the two coils, as well as their respective resistances, are so proportioned to one another that the attractive influence of the primary helix (when the arc is of its normal length) shall overcome the influence of the secondary circuit. Owing to the greater resistance of the latter, not more than one per cent. of the main current is transmitted by the fine wire helix, but its magnetic influence is rendered considerable by its greater number of convolutions.

From the above description it is clear that since the electric current has two routes from one terminal of the lamp to the other, the one through the arc and the other independent of it, it follows that should the arc become too long, its resistance will increase, and a larger proportion of the current will be shunted through the fine wire helix, while the strength of that in the thicker helix will diminish, the resultant magnetic influence on the plunger will be reduced, and the upper carbon will be brought closer to the lower; on the other hand, if the arc becomes shorter than its normal length, its resistance is reduced, more current flows through the primary helix, and less through the secondary, and the carbons are drawn farther apart.

Fig. 11 is a diagrammatic sketch showing the course of the primary circuit, and illustrating the general principle by which the arc is controlled; it also shows the short circuiting contrivance by which any accident to one lamp, or irregularity of working, cuts it out of the general circuit, and does so without exercising any influence upon the other lamps in the series. In this diagram,  $x$  and  $y$  represent the two terminals of the lamp, which, in most cases, consists of hooks, which, being hung over pins attached to the ceiling—and which are in connection with the line circuit—place the lamp in circuit with the machine. The current entering at  $x$  is transmitted through the two hollow bobbins,  $h$  and  $h^1$ , in parallel circuit, the outgoing ends being joined together and connected to the upper carbon holder,  $z$ , and if the carbons

are in contact, the current flows through them, and by the vertical rods of the lamp to the terminal hook, *y*; the effect of this is to convert the solenoids, *k* and *k'*, into magnets, which, by drawing into themselves the two iron plungers, *n* and *n'*, lift one edge of the washer clutch, *w*, which by its oblique action, seizes the carbon rod (much in the same way as a tent-rope tightener grasps its cord) and lifts the upper carbon until its influence is balanced by that of the fine wire helix, which, it must be remembered, surrounds the thicker coil.

The short-circuiting apparatus shown to the left of the carbons (see Fig. 11), consists of an electro-magnet, *t*, wound with a thick and a fine wire coil similar to those of the regulating solenoids, but both wound in the same direction. When the thick wire circuit of this magnet is

system are, before being used, a foot long, and are electro-plated with a thin covering of copper; they last for about eight hours, during which time about 9½ inches of the positive and about 4 inches of the negative carbon are consumed. When, however, the lamps are required to burn for a longer period, double carbon lamps are employed, fitted with two pairs of carbon holders, as shown in Fig. 9, and each is controlled in the same way as in the single carbon lamp, but the controlling apparatus is not duplicated. When the lamp is put into action, the arc is formed between one of the pairs of carbon, and, when they have burned out, the other pair automatically starts into action and continues to burn until it is in turn consumed; in this way the time of burning is doubled, and in order to extend the period of burning, it is

takes its grip before the other begins to act, and consequently lifts its corresponding carbon higher than its neighbor; the consequence is that only one arc is established, viz., across the lesser distance, and in all the subsequent feeding and controlling the pair of carbons first started are alone affected, because, although both carbons are raised and lowered together, the lower end of the reserve carbon is always higher than the other by the difference in the height of the two pairs of jaws on the frame, *k*. A time arrives, however, when, owing to the shortening of the consuming carbons, they can no longer meet when the frame is dropped, and the current by which they are again separated can only be transmitted by the reserve carbons coming into contact; the circuit is thereby completed, the new carbons are separated, and the

and with a remarkably small loss, and this is of especial advantage where several lights have to be employed, because if there are as many long conductors as there are lamps, then the whole of the loss of current due to the resistance of the cables must be borne by each lamp, whereas if a number of lights can be included in a single circuit, the loss of current from the resistance of conducting cables is equally divided among all the lamps in the series. There are, of course, commercial advantages in burning a number of lights in a single circuit from one machine, for there must necessarily be an enormous increase in prime cost in the adoption of a number of dynamo-electric machines in the place of one, as well as in the multiplication of conducting cables, and the advantage in point of attendance and repairs is obviously in favor of the

Fig. 8.

Fig. 9.

Fig. 10.

## THE BRUSH ELECTRIC LAMP.

complete, it forms a shunt of low resistance between the terminals, and, therefore, short-circuits the lamp, transmitting the current to the main circuit. Now, the fine wire wound upon this magnet is in circuit with the fine wire of the regulating solenoids; it follows, therefore, that if the failure of the arc, or through its becoming

only necessary to employ a lamp with a third pair of carbons, when it will be capable of illuminating for 24 hours, each additional pair of carbons extending the period of burning for another 8 hours.

The change from the one pair of carbons to the new pair is effected by purely mechanical

arc between them continues to be controlled by the magnet and clutch in the same way as the first arc was.

The great simplicity of the Brush lamp may not at first be appreciated from the above description, for in the action of the lamp, electric phenomena of a somewhat complex nature oc-

single machine system.

With respect to the advantage of being able to operate a number of lights at a considerable distance from the machine, it is an interesting fact that the sixteen lights, which are now in regular use for the illumination of Charing Cross terminus, are actuated by a machine work-

Fig. 11.

Fig. 13.

Fig. 12.

abnormally long, or through any considerable increase in its resistance, a larger proportion of current be diverted through the fine wire circuit, the attractive force of the electro-magnet, *t*, would be increased and its armature, *a*, which is attached to the pivoted lever, *b*, would be attracted, the contact pieces, *m* and *m'*, would thereby be brought together, and the terminals would be short-circuited through the thick coil, *m*, and the resistance spring, *r*. By thus short-circuiting the terminals through a route altogether independent of either the fine or the thick wire solenoids, their magnetic action ceases, and either the upper carbon is dropped, or, if it is burned out, or from any other cause the arc is not established, the contact pieces, *m* and *m'*, are held firmly together by the attraction of the magnet, *t*, and the current flows past the faulty lamp to the others in the series, its extinction calling attention to it, while the other lamps become proportionately brighter.

The carbon pencil consumed under the Brush

means, and by a contrivance the ingenuity of which is only measurable by its extreme simplicity. This little apparatus will be understood by reference to the explanatory diagram, Figs. 12 and 13, which also more clearly illustrate the action of the washer-clutch than the preceding figure. *c* is the hollow solenoid or "sucking magnet," which exercises a magnetic influence upon the soft iron plunger, *p*. The rising or falling of this plunger raises or lowers the little frame, *k* (shown in both figures), by the intervention of the lever, *l*; *r* and *r'* are the carbon rods which pass vertically through the casing of the lamp, and *w*<sup>1</sup> and *w*<sup>2</sup> are the clutch-washers which surround them. One side of each of these washers passes between a pair of jaws forming part of the little frame, *k*, and when the latter is drawn upward, its action is first to tilt the washers, and then to cause them to clutch the rod on diagonally opposite corners. By the very simple device of making one pair of jaws a little higher than the other, it

cur; that is to say, the various courses of several different simultaneous circuits of different resistances have to be followed and considered, and this renders a description more complicated; but no one could examine a Brush lamp with its case removed or watch its action without being struck with its extreme simplicity and remarkable efficiency.

The Brush system of electric lighting is remarkable as being the only one which, to our knowledge, is capable of establishing a large number of large arc lights in a single circuit, and it would be difficult to overestimate the great value of this distinctive property for the purpose of public illumination. Under other large arc systems each lamp must have a separate machine, and there must, of course, be as many lengths of leading wires as there are lamps and machines. It possesses also another very special advantage, and that is that a series of lights may be maintained by the Brush system at a great distance from the machine,

in the Anglo-American company's works in Lambeth, and that within a few weeks a large area of the city of London will be illuminated by the same system by forty lamps, all operated in one circuit by a machine working in the Lambeth works.—*Engineering*.

ALASKA PEBBLES.—D. H. Jackson, who recently returned from Alaska, brought home with him a lot of quartz pebbles as curiosities, they being worn as smooth and almost as round as marbles. As they were nearly pure white in color, no one thought of their containing any metal except Supt. Boyle, of the Alta, on the Comstock. He thought the pebbles looked as if they might contain something of value. The *Enterprise* says he had some of them pounded up and assayed, when they showed gold at the rate of \$16 per ton. The pebbles were picked up at the mouth of the Chiloat river, where they form the head. Good mines will probably be found somewhere up that river.

## Color of Minerals.

In a recent number we had a brief article on this subject, giving the general principles with regard to the color of minerals. Some examples of color and names will be valuable to miners. The following eight colors are selected by Dana as fundamental to facilitate the employment of this character in the descriptions of minerals: white, gray, black, blue, green, yellow, red and brown. From the chapter on this subject in Dana's Text-book of Mineralogy, we take the following:

## The Metallic Colors are:

1. *Copper-red*—native copper. 2. *Bronze-yellow*—pyrrhotite. 3. *Brass-yellow*—chalcopyrite. 4. *Gold-yellow*. 5. *Silver-white*—native silver, less distinct in arsenopyrite. 6. *Tin-white*—mercury, cobaltite. 7. *Lead-gray*—galenite, molybdenite. 8. *Steel-gray*—nearly the color of fine-grained steel on a recent fracture; native platinum, and palladium.

## The Non-metallic Colors are:

A. WHITE. 1. *Snow-white*—Carraramarble. 2. *Reddish-white*—some varieties of calcite and quartz. 3. *Yellowish-white*—some varieties of calcite and quartz. 4. *Grayish-white*—some varieties of calcite and quartz. 5. *Greenish-white*—talc. 6. *Milk-white*—white, slightly bluish; some chalcedony.

B. GRAY. 1. *Bluish-gray*—gray, inclining to a dirty blue color. 2. *Pearl-gray*—gray, mixed with red and blue; cerargyrite. 3. *Smoke-gray*—gray, with some brown; flint. 4. *Greenish-gray*—gray, with some green; cat's eye, some varieties of talc. 5. *Yellowish-gray*—some varieties of compact limestone. 6. *Ash-gray*—the purest gray color; zoisite.

C. BLACK. 1. *Grayish-black*—black, mixed with gray (without any green, brown or blue tints); basalt, Lydian stone. 2. *Velvet-black*—pure black; obsidian, black tourmaline. 3. *Greenish-black*—augite. 4. *Brownish-black*—brown coal, lignite. 5. *Bluish-black*—black coal.

D. BLUE. 1. *Blackish-blue*—dark varieties of azurite. 2. *Azure blue*—a clear shade of bright blue; pale varieties of azurite, bright varieties of lazulite. 3. *Violet-blue*—blue, mixed with red; amethyst, fluorite. 4. *Lavender-blue*—blue, with some red and much gray. 5. *Prussian-blue*, or Berlin blue—pure blue; sapphire, cyanite. 6. *Smalt-blue*—some varieties of gypsum. 7. *Indigo-blue*—blue with black and green; blue tourmaline. 8. *Sky-blue*—pale blue with a little green; it is called mountain blue by painters.

E. GREEN. 1. *Verdigris-green*—green inclining to blue; some feldspar (amazon-stone). 2. *Celandine-green*—green with blue and gray; some varieties of talc and beryl. It is the color of the leaves of the celandine (*Chelidonium majus*). 3. *Mountain-green*—green with much blue; beryl. 4. *Leek-green*—green with some brown; the color of leaves of garlic; distinctly seen in prase, a variety of quartz. 5. *Emerald-green*—pure deep green; emerald. 6. *Apple-green*—light green with some yellow; chrysoprase. 7. *Grass-green*—bright green with more yellow; green diallage. 8. *Pistachio-green*—yellowish green with some brown; epidote. 9. *Asparagus-green*—pale green with much yellow; asparagus stone (apatite). 10. *Blackish-green*—serpentine. 11. *Olive-green*—dark green with much brown and yellow; chrysolite. 12. *Oil-green*—the color of olive oil; beryl, pitchstone. 13. *Siskin-green*—light green much inclining to yellow; uranite.

F. YELLOW. 1. *Sulphur-yellow*—sulphur. 2. *Straw-yellow*—pale yellow; topaz. 3. *Wax-yellow*—grayish yellow with some brown; blende, opal. 4. *Honey-yellow*—yellow with some red and brown; calcite. 5. *Lemon-yellow*—sulphur, orpiment. 6. *Ochre-yellow*—yellow with brown; yellow ochre. 7. *Wine-yellow*—topaz and fluorite. 8. *Cream-yellow*—some varieties of lithomarge. 9. *Orange-yellow*—orpiment.

G. RED. 1. *Aurora-red*—red with much yellow; some realgar. 2. *Hyacinth-red*—red with yellow and some brown; hyacinth garnet. 3. *Brick-red*—polyhalite, some jasper. 4. *Scarlet-red*—bright red with a tinge of yellow; cinnabar. 5. *Blood-red*—dark red with some yellow; pyrope. 6. *Flesh-red*—feldspar. 7. *Carmin-red*—pure red; ruby sapphire. 8. *Rose-red*—rose quartz. 9. *Crimson-red*—ruby. 10. *Peach-blossom-red*—red with white and gray; lepidolite. 11. *Columbine-red*—deep red with some blue; garnet. 12. *Cherry-red*—dark red with some blue and brown; spinel, some jasper. 13. *Brownish-red*—jasper, limonite.

H. BROWN. 1. *Reddish-brown*—garnet, zircon. 2. *Clove-brown*—brown with red and some blue; axinite. 3. *Hair-brown*—wood opal. 4. *Broccoli-brown*—brown with blue, red and gray; zircon. 5. *Chestnut-brown*—pure brown. 6. *Yellowish-brown*—jasper. 7. *Pinchbeck-brown*—yellowish brown with a metallic or metallic-pearly lustre; several varieties of talc, bronzite. 8. *Wood-brown*—color of old wood nearly rotten; some specimens of asbestos. 9. *Liver-brown*—brown with some gray and green; jasper. 10. *Blackish-brown*—bituminous coal, brown coal.

## Peculiarities in the Arrangement of Colors.

**Play of Colors.**—An appearance of several prismatic colors in rapid succession on turning the mineral. This property belongs in perfection to the diamond; it is also observed in precious opal, and is most brilliant by candle-light.

**Change of Colors.**—Each particular color ap-

pears to pervade a larger space than in the play of colors, and the succession produced by turning the mineral is less rapid; Ex. labradorite. **Opalescence.**—A milky or pearly reflection from the interior of a specimen. Observed in some opal and in cat's eye.

**Tarnish.**—A metallic surface is tarnished when its color differs from that obtained by fracture; Ex. hornblende. A surface possesses the steel tarnish when it presents the superficial blue color of tempered steel; Ex. columbite. The tarnish is *irised* when it exhibits fixed prismatic colors; Ex. hematite of Elba. These tarnish and iris colors of minerals are owing to a thin surface film, proceeding from different sources, either from a change in the surface of the mineral, or foreign incrustation; hydrated iron oxide, usually formed from pyrite, is one of the most common causes of it, and produces the colors on anthracite and hematite.

**Asterism.**—This name is given to the peculiar, star-like rays of light observed in certain directions in some minerals by reflected or transmitted light. This is seen in the form of a six-rayed star in sapphire, and is also well shown in mica from South Burgess, Canada. In the former case it has been attributed by Volger to a repeated lamellar twinning; in the other case, by Rose, to the presence of minute inclosed crystals which are a uniaxial mica, according to DesCloizeaux. Crystalline planes, which have been artificially etched, also sometimes exhibit asterism. In general, the phenomenon is explained by Schrauf as caused by the interference of the light, due to fine striations or some other cause.

## Painted Rocks.

We give on this page a view of objects of historic interest, the "painted rocks" of Arizona. Mr. Conklin's account of his observations on the painted rocks is as follows: One of the leading features of interest to the traveler in the

THE PAINTED ROCKS OF ARIZONA—Piedras Pintadas.

mesa land of Arizona is the system of prehistoric landmarks he is constantly coming in contact with. It is in these features that Arizona presents herself as the land for the archaeologist and all curious minds. Among the foremost of these are the "Painted Rocks." (*Piedras Pintadas*.)

About six miles from Oatman's Flat, on an extensive plain, encircled by the famous Arizona mountains, is to be seen the largest and most perfect specimens of these Painted Rocks (*Piedras Pintadas*). They are in the Gila valley, 120 miles from Tucson, latitude, 33°, longitude, 113°. To stop and examine these wonders of the pre-historic age, is only to enhance the great enchantment that waylays the traveler in Arizona on every hand. They are a mass of rocks, evidently piled by some physical power, ages ago. They are massed together in a heap about 50 feet high, with a proportionate base; and while some are of a size that may be lifted by a man, others might be ranked with howlders. On these rocks or stones, are various figures and images. Figures, geometrical, comic, and anatomical. There are squares, circles, triangles, crosses, snakes, toads and vermin, men without heads and dogs without tails.

**A CHEAP PUMP FOR MINES.**—At the Yellow Jacket mine on the Comstock, when about to commence the attack on the water of the lower levels, Superintendent Taylor caused a lift-pump to be made for use in the main shaft. For the barrel of the pump he took a section of ordinary 14-inch pump column, and fitted into it the necessary bucket and valves. Although, owing to the altitude, a lift-pump will only raise water effectively to a height of about twenty feet, yet this was found to do excellent work as far as it would work at all. The only disadvantage was the trouble of the frequent lowerings required. Mr. Taylor was so well pleased with the work done by the first pump that he caused a second to be made, the pair can then be shoved down a side at a time, always keeping one at work in the water. The cost of rigging up such a pump to any company who happen to have on hand a spare pump column is a mere trifle. In many situations such pumps will be found exceedingly useful in lifting water to the tanks of the main line of plunger-pumps.

## Miners' Rights to Surface Ground.

In the case of the National Mining and Exploring Co. against Richard McNeal *et al*, tried in the District Court at Helena, Montana, a short time since, several very important mining questions were ruled upon by Chief Justice Wade. Plaintiff had located the Little Muddy lode, the location embracing a parallelogram 1,500 ft. long and 600 ft. wide.

Subsequently to the filing of this location in the Recorder's office, defendants entered within the boundary lines of the Little Muddy location, discovered and sunk a shaft upon a lead whose apex appeared upon the surface there, named their discovery the Mac Lode and located the same, the boundary lines of their location embracing several hundred feet of the surface ground of the Little Muddy location.

Plaintiffs sued defendants as trespassers and for an injunction, etc. Defendants claimed that plaintiffs' Little Muddy location was not valid in law for several reasons, among them because of a failure to make a discovery of a valuable mineral deposit with a well defined wall, and because the location was not made along the line of the vein, it being claimed that the side lines extended more than 300 ft. from the center of the vein.

The court held that the wall rock, etc., were essential to a proper discovery to entitle a party to make a valid location, but that if a proper discovery had been made the failure to make the boundaries of the location correspond to the course of the vein would not affect the plaintiff's right to the possession of his surface ground; and that an entry by another person upon such surface ground for the purpose of making a discovery would be unauthorized; and that entry would be a trespass.

The instructions upon this point were voluminous, but the following embraces the principle.

THE PAINTED ROCKS OF ARIZONA—Piedras Pintadas.

pal points involved with reference to the question of surface rights:

"It is not necessary in order to entitle a party to make a location of a lode and surface ground that the exact course of the vein should be accurately described. A party making a location will be presumed to have made in accordance with the course of the vein until the contrary is shown, the consequence of a mistake not being to deprive him of the surface ground contained within the boundaries of his location, but only affect the vein itself by circumscribing its limits.

## Jumping Claims.

Behold the prospector who wandereth over the face of the earth.

He traverseth the hills and picketh the barren mountains with his pick.

The pangs of hunger grip his bowels in the morning, and at night he lieth down with only a blanket to cover him.

And the graybacks come forth and rend him. And he lifteth up the voice of lamentation in the wilderness and crieth aloud to heaven:

"Why has this affliction come upon me, and why do the terrors of hell compass me round about?"

And while he sleeps, the wolves devour his substance.

And when he findeth the croppings, he diggeth in the ground and sticketh up the location notice on a board.

He then hieth to the valleys, and sayeth to the capitalist:

"Hearken unto me, for I have struck it big. Here are the samples from the ground, and behold the gold maketh lousy the rock with its richness."

And the twain return to find others toiling upon their claim.

And the prospector graspeth his gun, saying:

"Get ye from here, for this is holy ground." And a fire coming out of the hush smiteth him on the hip, and he calleth with a loud voice:

"I'm done for; take off my boots!"

And he giveth up the ghost and is gathered to his fathers.

And, behold others worked the mine.—*Nevada Monthly*.

## Arizona's Wealth.

The mineral resources of this Territory of Arizona are somewhat marvellous. The developments being made show such an abundance of gold and silver ore as has been never dreamed of before. Even those who have always felt full confidence in the mineral outcome of our Territory are astonished at this numerous wonderful developments being made. Yet the present condition of this prospective value of our resources is still in its infancy. But a fraction of the mineral-bearing portions of Arizona has as yet been prospected, and thousands of mines are to be discovered that will yield an abundance of wealth to the world, equal to the best. In Northern Arizona there are large stretches of country, yet untroubled by the foot of civilized man, that are undoubtedly well supplied with mineral leads as the best yet found. As the country is settled up, the daring prospector will find his way into the unexplored hills and reap the rich reward of wealth there awaiting him. Even about the most developed portion of our Territory but a small portion of the mineral leads of great value has been discovered, and the advancing years will bring new developments as startling as some of the present ones. There is practically no limit to the mineral resources of Arizona, and the rule that its mines increase in value the deeper they are developed, surrounds our resources with a confidence in their permanence that will bring ready capital to our doors, seeking investment in mines. Time will show that a better field for profitable mining exists in Arizona than in Sonora, and the mistake of precipitate investments in the latter State will soon react in favor of our own Territory, and a legitimate boom of prosperity will be felt throughout the whole country.—*Tucson Citizen*.

**SAVING SULPHURETS.**—We take the following from the Nevada Transcript: The Providence mining company have ordered 16 Frue concentrators for their new 40-stamp mill, and the machines will arrive here this week. The first Frue machine was brought to this county two years ago last month, and the invention was then coldly received. Since then it has been growing in favor. Of the mines in this locality, the Murchie has eight, the Wyoming eight, the Merrifield eight, the Nevada City four, the Mountaineer two and the Pioneer Reduction Works two, making, when added to the ones for the Providence, 48 in the township. We do not know of a solitary instance where they have failed to give perfect satisfaction. The sulphuret production of every mine adopting them has been more than doubled by their use. Several other mines hereabouts are making arrangements to put them in their mills.

**TELL US THE NEWS.**—We emphatically second the following from the Nevada Transcript: At a time when the mining industry is encouraged by the confidence of the investing public, there is no good reason for the withholding of information of interest to shareholders. The present is the most momentous, and shareholders have a right to know, not only as to the prospects and workings of the mine, but also of the management. The press stands ever ready to give reliable information; and when shareholders ask for particulars as to the properties they have invested in and are rebuffed, the press has but one remedy, and that is exposure whenever and wherever the fraud is found. Wild cat mining must be rebuked. There are too many good dividend-paying properties, whose reputations must not be tarnished by even the remotest contact with the illegitimate.

**THE JOHN DAY COUNTRY.**—A dispatch from Portland, Oregon, says: Capt. Chas. Bendire, of the First Cavalry, stationed at Walla Walla, an eminent naturalist, will visit the John Day country for the purpose of collecting fossils and other material for the Smithsonian Institute, and at the same time will measure the streams and collect data regarding birds, trout and reptiles. Capt. Bendire takes issue with Prof. Jordan and other scientists claiming that the celebrated redfish of the Walla Walla lakes to be the blue-back silver-side salmon. His collection of birds' eggs—the largest in this country, and for which he has been offered \$10,000—will be put in as perfect form as possible and presented to Harvard University.

**DUN GLEN.**—Deputy Assessor Buckner informs the Silver State that times are lively in Dun Glen, and there is considerable activity among mine owners. The new ore body in the Lang Syne is looking well and the ore is said to be rich in gold. The Auburn company have 20 men at work developing their mines, and the prospects are quite encouraging in many of the openings on the ledges. The company, he learned, now feels safe in having a mill built, as there is ore enough in sight to keep it running for a long time.

**I X L** and Pike Hollow districts are in Churchill county, Nevada. I X L district is on the east side of the Stillwater range, while Pike Hollow is on the west side. It takes a long time to develop a mining camp with limited means, and this has been the unfortunate circumstance of I X L. But there seems to be no doubt of the ultimate success of this camp, although Pike Hollow has, to-day, the brightest prospects, and will probably have the first mill in active operation.

## Botanizing in Arizona.

EDITORS PRESS:—As you saw us at the Oakland depot when starting for Arizona, and expressed so much interest in our journeys and successes, we take pleasure in reporting proceedings thus far.

No lovelier scene, so far as flowers go, can be met with anywhere than the fields, roadsides and hills of the San Joaquin valley at the time of our rapid passage through them on the Overland train. Belts of gold, and brown, and orange, and white striped the green carpeting in the most beautiful manner. My artist wife often exclaimed: "I have never seen one-half as much color before on a landscape. If I should put one-fourth as much on canvas, everyone would call the picture overdrawn."

Unfortunately, as at present arranged, the passenger train reaches Merced late, and traverses all the Tehachapi region, with its noted loop, also the curious Mohave desert, in the night. Emerging from the long San Fernando tunnel into the Los Angeles fields, we were disappointed to find them dry and backward this season, so falling below in rich display of color the lower San Joaquin described.

So, also, was found the whole valley traversed by the railroad to Colton. The San Bernardino hills at the same date of last year were the most glorious objects my eyes ever beheld; this year scarcely relieved from haze to crown from the dull brown, dry herbage and red soil by a single stripe of crimson poppies.

On the San Geronimo pass the flora was better again, the highest point being quite radiant with profuse flowers, but as soon as the descent began into the horrible Colorado desert, goodbye to the last vestige of green or flowery things.

The traveler who has heretofore crossed this desert in the night (as per late time-card) and thought himself cheated of fine scenery, can now, by new regulations, cross it by day, but as for sights, mercy on us! You look out through closed windows upon a glaring, white alkali plain, from which the train shakes up and envelopes all in a dense cloud of hot, pungent dust that insinuates itself through the window casings and nearly stifles you. When, happily, the dust subsides, and green bushes of the palo verde begin to appear, and the green line of poplars bordering the Colorado are descried, the conductor, if asked, informs you that you have just passed over the bed of an ancient sea, and for some 17 miles you were over 250 ft. below the level of the ocean.

The Colorado, muddy, shallow and full of snags, seems a wonderful river to persist so long a time in connecting the great rivers of the Rocky mountains by his deep winding canyons with the Gulf of California. On its western bank in California is located the little town of El Rio, composed of a quartz mill and other buildings owned by W. W. Van Arsdale. Here we stepped off and botanized the river bottoms and hills for two days, enjoying the hospitality of Mr. V. and family. A few leguminous plants, particularly shrubs, constitute the principal flora of the region. Among these are the two kinds of mesquite (*Prosopis*), the iron wood (*Olneya*), the three species of palo verde (*Parkinsonia*), several species of *Dalea*, etc. Chief of these in attractiveness are the several species of palo verde, or green stick, as its Spanish name implies. The whole bush, which is sometimes almost tree-like in proportions, is of a bright green color, owing to the character of the bark. It is always thin and never covered by the usual corky, outer bark. The long waving or pendent branches are entirely leafless for most of the year. Only for a few days in winter the merest little apology for leaves appear, soon falling away.

This seems to be an adaptation of subject to environment. Through the cycles of time, this tree has suffered more and more from the scorching of its leaves or lungs by the excessive heat, and so has learned to dispense with them altogether, and now changes its cambium to sap by aeration, through its evergreen and thin bark.

## In Arizona.

At the historic old adobe city of Yuma, on the other bank of the Colorado, we paused for only an hour. Not a green plant to be seen, except the ever-present creosote bush (*Larrea Mexicana*), gave opportunity to study Indian character—the subjects of all ages and both sexes being abundant. These Yumms are now a peaceful, non-hunting tribe, still governed by the noted old chief, Pascual—straight as an arrow, over six feet high, and said to be about 100 years old. His mother, a very mummy in appearance, lives with the chief, near the old fort. Strong belief is entertained that she must be about 120 years old.

The next pause was at Casa Grande, a station named from the famous old Aztec ruin about 20 miles distant. Here we had an interrum of 15 minutes with the celebrated Pauline Cushman, once a very successful Union spy—equally heroic in a dozen other noble and hazardous undertakings.

Three hours after, the train rolled along through the green grain fields of the sunken Santa Cruz and brought up at the new addition to the old Spanish town of Tucson, the largest and richest city between Los Angeles and the Gulf of Mexico. A day was all we could spend looking over this quaint old town, with its inhabitants of nearly all nations, particularly dark ones, but fast being brightened by the admixture of dozens of white persons by

every train since just one year ago. The next day we hired a wagoner to bring us and our botanical paraphernalia, bedding, provisions, etc., out here, six miles to a stick-and-mud cabin, just at the base of the first foothills of the

We have established a temporary camp in a cave near a little spring at the very base of the highest peak of the mountains, and often visit it two or three nights in succession. From this secure retreat from prowling natives we sally

AN APACHE INDIAN.

wonderful Santa Catarina mountains five miles away. This is headquarters for a fortnight or so, being a good place to dry out and study plants. The plains are very dry and barren, but the mountains bear their usual flora.

out in the early morning packed with botanical portfolios, food and water for the day, and at once proceed to climb the rugged steep, contending all the way against the thorns of the mesquite, the bayonets of yucca and the fiendish

AN APACHE SQUAW AND PAPPOOSE.

We packed ourselves, (wife and I), with blankets, provisions, botanical paper, etc., at once and started for the distant mountains, toiling along amidst the hot sand or over the numerous hills, beset with thorny mesquite bushes or with the ten-times-more-to-be-dreaded cacti, with keen, harped, stinging needles. Oh how we have been punished whenever too hasty or heedless.

needles of cacti, each of these terrible defensive plants being found clinging to the very pinnacles of these mountains, as if guarding vast treasures.

After a long day of weary, painful climbing we retreat to the cave and pass the night. Next day we must rest and dry out our plants gathered. The second day we climb again, and so the rare or new plants of the mountains of the

Santa Catarina are being gathered. Thus are your late Oakland citizens rusticated and enjoying themselves, while adding now and then a new plant or a valuable fact to the common stock of knowledge.

To-morrow we return to the cave and from there commence a week's exploration of the highest peaks and passes, with what success or adventures you may be advised, if such items are desired.

J. G. LEMMON.  
Botanical Camp, Foothills of Santa Catarina, Arizona.

## Clay Deposits of California.

The matter of the clay deposits of the State is too important to be put off with a general notice. It will be the duty of the State Mineralogist to thoroughly investigate the known deposits, and to publish all information that can be obtained relating to them and to their manufacture. Samples from various sources may be seen in the State Museum, with some of the ware, useful and ornamental, of California manufacture. It is to be hoped in the future that more numerous samples, both of the crude clays and their products, will be added to the collection. This material is quite extensively used in building in California, as sewer-pipes, tiles, chimney-tops, fire-brick, and also manufactured into many useful forms. A few analyses have been made, which are given below.

The following is an analysis of clay from a deposit at Lincoln, Placer county:

MECHANICAL ANALYSIS.	
Coarse sand.....	10.53
Fine sand.....	10.79
Combined water.....	10.60
Hygroscopic water.....	1.00
Pure clay.....	07.23
100.00	
CHEMICAL ANALYSIS.	
Silica.....	41.80
Alumina.....	33.73
Combined water.....	0.00
Hygroscopic water.....	1.02
Carbonate of lime.....	2.04
Magnesia.....	1.02
Soda.....	3.46
Sesquioxide of iron.....	2.12
Loss.....	2.66
100.00	

The above sample is known to the potters as "white non-plastic clay."

The following is an analysis of a sample of clay from the same locality, known as "blue plastic clay":

MECHANICAL ANALYSIS.	
Coarse sand.....	3.30
Fine sand.....	23.52
Combined water.....	10.30
Hygroscopic water.....	.80
Pure clay.....	50.58
100.00	
CHEMICAL ANALYSIS.	
Silica.....	44.82
Alumina.....	34.64
Combined water.....	8.37
Hygroscopic water.....	1.27
Carbonate of lime.....	3.00
Magnesia.....	.99
Soda.....	4.74
Sesquioxide of iron.....	1.80
Loss.....	.44
100.00	

The following is a mechanical analysis of clay from Cook's ranch, near Lincoln, Placer county:

Coarse sand.....	5.30
Fine sand.....	3.77
Hygroscopic water.....	4.70
Pure clay.....	80.23
100.00	

This clay was almost free from iron, and was very plastic and tenacious; it had a strong argillaceous smell, and when baked was very refractory. The sand washed out was nearly pure silica, which for coarse ware or for fireproof material is not objectionable.

## The Aborigines of Arizona.

Now that the Territory of Arizona is coming into prominence as a field of agricultural and mining industries, being pierced by a railway and populated by many immigrants, it is timely to recur for a moment to the people who are being supplanted, and whose wild life is daily being curbed and checked. One of the Indian tribes inhabiting Arizona is the Apaches, known everywhere as among the worst, the most treacherous and relentless of the Indian race. Their raids have brought grief to many travelers or settlers in their domain, and their bad name has been spoken with execration in many quiet neighborhoods at the East, as their murders have robbed peaceful firesides of those who have gone out on ventures or in the service of the country.

Our engravings show typical forms of the Apache Indians, as secured by Mr. E. Conklin for his "Picturesque Arizona." The Apaches are of medium size, physically quick and active, and are capable of enduring great hardships. Their muscles of locomotion have been developed to the fullest extent, and they are capable of running with great rapidity. Intellectually, they are very shrewd. Since the Apaches have been brought on the reservation they have undergone a great change, and appear like different people.

LOOSE PULLEYS.—Loose pulleys require constant attention and much oil, and are very hard on the belt. It is best to have them a trifle smaller than the tight pulley, and with a step or flange running up to the diameter of the tight one. This takes the strain off the belt and the friction from the pulleys.

## Idaho Territory and Its Resources.

[From our Special Traveling Correspondent.]

Idaho is one of the least known, and yet one of the richest and most attractive of our Territories. It was organized in 1862, and contains an area of over 58,000,000 acres, situated between latitude 42° and 49° north, and longitude 34° and 40° west. It is bounded on the south by Utah and Nevada, west by Oregon and Washington, north by British Columbia, and east by Montana and Wyoming. The greatest length is 485 miles, and smallest width about 50 miles. It is divided into fifteen counties—Ada, Alturas, Bear Lake, Boise, Cassia, Custer, Idaho, Kootenai, Lahtoh, Lemhi, Nez Perce, Oneida, Owyhee, Shoshone and Washington. Governor Caley Lyon, of Lyonsdale, referred to it as "a land of Italian emmure and Syrian winters;" but a noted traveler who once happened to visit it late in the year took exception to this flight of fancy, and thought that although her emmure may outshine Arah the Blest, he should have said Siberian winters.

Now, I cannot coincide in either of these opinions, and have my captious objection on actual experience derived during a residence of several years in the mountain regions of this Territory. The climate of Idaho is generally equable and balmy in summer, with deep snow in the mountains and heavy rains in the valleys during the winter months; mercury rarely falls to 10° below zero in the most elevated mining camps; and cattle, sheep and horses roam over the extensive stock ranges without shelter or prepared feed the year round.

The elevation of the Territory varies from 2,000 ft. in the lower Snake River valley to 10,000 in the Saw-Tooth mountains. The general character of the surface is exceedingly mountainous and rugged. Snow-capped peaks may be seen at all points of the compass. Below, there are rolling hills and benches, which afford excellent pasturage during summer months; and still lower down are measureless plains, mostly covered with sagebrush. As a rule, all the valleys have an inexhaustible soil, in which cereals, vegetables and fruits grow and ripen without more care than that which is bestowed on them in California; but the most extensive one of them all has scarcely yet been touched by the plow or harrow, and therefore, has all the appearance of being a vast desert. I refer to the Snake River valley, which derives its name from that dim and crooked artery of the great desert's heart, and extends through the entire breadth of this Territory.

The smaller valleys, such as Boise, Weiser, Payette, Clearwater, Raft, etc., are also watered by magnificent streams, and most of them are already dotted by pleasant farms. Still, there is plenty of fertile government land left for those who desire to avail themselves of the Homestead Act, and many emigrants who have passed through this country on their way to Oregon and Washington in search of new homes, are now returning to settle among green-clad hills of the "gem of the mountains."

The Shoshone, or Great Falls of Snake river, called by the Indians Pah-chu-lak-a, signifying gift of the Great Spirit, are equaled only by Niagara, and the river has many other picturesque falls within 40 miles of these. Hundreds of springs also gush forth from the basaltic walls, and lashed into silver spray they leap down into the stream below. These natural curiosities are supposed to be the resurrection and new life of rivers that have died and been buried in the desert many miles away.

The country also abounds in hot springs, mountain lakes, ice caves and salt deposits, but its great wealth is in the gold and silver mines, discovered and undiscovered. A satirical tourist once remarked that the Rocky mountains, Sierras and intervening country, must be infinitely rich in minerals, because it is worthless for anything else. Without attempting to refute the latter part of the assertion, I shall send you with this a description of a few of the most noted mining districts of the Territory, and start in with the one in which I am at present holding forth—Wood River. [This letter will be found in another column.—EDS. PRESS.]

A. L. M.

LAUREL HALL.—The closing exercises of this well-known institution for the year 1881 show the esteem in which it is held and the extent of its patronage. The past year was very gratifying to the friends of the institution, and the ensuing term, if the expectations of the Principal are fulfilled, will be even more successful. The rising fortunes of Laurel Hall are a source of pleasure to all who are acquainted with the untiring efforts of Mrs. Buckmaster, and her creditable history as an instructor in this State. The announcement of the coming term may be found in a card in another column.

"THE BOOK OF THE SWORD" is the unique title of a work which has been in progress for many years, by Capt. Richard Barton. It is now fast advancing toward completion. The history of the sword is the history of man, and the author begins with the beginning—with the sword of wood. The work will be properly illustrated.

MINING men from New York inform us that moneyed men are now willing to put their capital into good properties for the purposes of development. They won't look at wild-cats.

## Geological and Botanical Collections.

EDITORS PRESS:—Is there a place in this State where specimens, botanical and geological, ancient and existent, are classified, while the sender holds a numbered duplicate? If not, in the interest of the pupils of our schools, I wish some such an office was instituted.

Could not a "Teacher's Scientific Club" be organized, for the benefit of our instructors and pupils from Siskiyou to San Diego, until specimens are gathered from every one of its 139,000 square miles of territory—a room has found furnished with long, high, deep rows of shelves divided into sections, each representing a county, containing specimens of all its various soils properly analyzed and labeled, and cases of drawers in the center of the room for fossils, etc., and a paper interested in the cause of education devote a column to the proceedings of the "club," and a capable, enthusiastic professor of geology and botany, who will also act as curator in charge, to classify and report upon the collections as they are forwarded.

If such a "club" or office as the one described is already established in this State, all I have to say is, it is not efficiently advertised.

Are our children to grow up in ignorance of the rocks beneath their feet and the plants they see every day of their lives? We use Younman's botany and Gray's in many of our schools, and read various works on geology, entomology, etc., but none of them treat particularly of our own indigenous flora and fauna, and the works of the "Geological Survey," which bear directly on this subject, are out of the reach, in a pecuniary sense, of the masses we instruct in order to "elevate the top." "The Geology," Vol. 1st, (Vol. 2d and 3d, when completed), "Ornithology," "Manual of Flowering Plants and Ferns of California," should be deemed necessary and obligatory possessions of all our school libraries by our directors.

I should not like to know how many country teachers and their pupils in this State are acquainted with the proper analysis and classification of the weeds they daily tramp upon—our manzanita, laurel, Sequoia, chapparal, madrone, plants medicinal and ornamental; fossils, triassic, jurassic, cretaceous and tertiary deposits—for a knowledge of such statistics would be painful.

I wish to have some specimens examined, and am obliged to send them East. It is superfluous, also, to add that such a "club" would encourage original research, stimulate individuality, etc. Maybe among our pupils there would be Hugh Millers, Sedgwicks, Danas, if they had a wider environment. Will you not use your influence in introducing this subject among teachers and others.

MRS. MARY J. GATES.

Point Arena, Cal.

We publish the above not only to show that there is an interest prevailing on the subject to which it refers, but also to inform those interested that there are places where specimens are identified.

In the first place, as to the geological specimens: If they are sent to the University of California, the instructor of mineralogy will always be pleased to identify specimens, as far as can be done by comparison with the standard collection they have there. If it is anything new analysis will be made.

We have also in this city a State Mining Bureau at 313 Pine St., where there is a very fine and extensive collection of minerals, ores, and rocks of all kinds. Mr. Henry G. Hanks, the State Mineralogist, is one of the best off-hand identifiers in the country, and having a fine collection for comparison, can always determine a specimen. If it is new, he will have the State Chemist analyze it. Mr. Hanks is also collecting a fine technical library. Any information in his line he will cheerfully impart.

Then again, if a specimen is sent to the California Academy of Sciences, Mr. C. D. Gibbs, the Curator of Mineralogy, will always be pleased to have it identified.

As to botanical specimens, Dr. A. Kellogg, Curator of Botany of the California Academy of Sciences, will always cheerfully identify them. He has had large experience of California flora, and there is a very large collection of plants all identified, poisoned and labeled in the Academy Museum. This collection is very complete and full, and is the result of many years labor of intelligent collectors.

Of course people asking questions about specimens should send return envelope and stamp, and give full particulars.

THE AVA SUPAIS.—North of Prescott and in the Supai country, exists a fine mineral belt which must be utilized and become the property of the white man. The country is claimed by the Indians, and they expect protection in their rights. They have valuable orchards, good agricultural and grazing lands, all that an Indian desires. It seems to the Arizona Miner that the Government should envy their lands and set apart for their use all lands not mineral, and those containing the precious metal should be declared perfectly free to location by prospectors. Already, numerous parties are developing immense ledges in that country, and immediate action should be taken to insure them against interference on the part of the Ava Supais, who are an independent and quite well behaved people. The mines of Supai are within forty miles of the Atlantic & Pacific railroad, hence must become very valuable.

## Extravagant Prices for Prospects.

Probably there is no other one cause which "keeps back" new mining camps, more than the common custom of charging exorbitant prices for mere prospect holes. After a mine has been developed so as to show there is a lot of ore in sight and there are probabilities of a good deal more, it is all very well to charge high prices; but for mere prospect holes or "mines" with 15 or 20-ft shafts, when men charge \$10,000, \$15,000 or \$20,000 for them, they defeat their own ends. People bear of these things and fight shy of a camp or a country where the custom prevails. When a prospect is near a very rich mine, in a place where there is likely to be great chances of striking rich ore, people will pay a good price for it if only to make a "stock mine" for speculating purposes. But miners, as a general thing, will do better to ask reasonable prices for mines that are in reality only prospects.

Some remarks in this connection from the Nevada Transcript are worthy of note. It says: There are scores of good prospects in Nevada county that are idle to-day, for no other reason than that the owners hold them at extravagant prices. If they would reduce their figures to within reasonable bounds, there are plenty of our own citizens with the money and inclination to invest, if given a fair show, that would take hold and develop them. Under such an order of things it would not be necessary to rely upon capital from abroad coming in. An undeveloped mining claim is a good deal like an undeveloped farm. Much money has to be spent on it before it becomes productive. Before it is sufficiently opened up to yield a sum in excess of the cost of operation it is a dead-weight on the shoulders of the owners. Until the so-called market value of undeveloped deposits of gold-bearing ore and gravel decreases, there cannot be a full-fledged and healthy mining boom in any part of the country. Fancy prices on prospects are responsible for the limited amount of working mines in every camp on the Coast. We hope to see the citizens of Nevada county, than whom there are no more progressive people in the West, soon come to a realizing sense of this fact and act accordingly.

## Arizona's Future.

We take the following from the Arizona Journal: That this Territory is destined ultimately to become one of the most prominent and flourishing States of the Union we think there can be little doubt. Its agricultural advantages, climatic comforts and mineral resources invite and are securing a rapidly increasing population of the better class who will demand admission into the sisterhood of States. Political considerations may defer this consummation for an indefinite period, but its realization, at one time or another, is beyond question. The people who are now flocking to its settlements are, generally, respectable, intelligent, energetic and enterprising. They come here, of course, to make fortunes, but they are not nomadic and make homes as well. They possess efficient capacity to choose their own Governors, Judges, Secretary of State, and all other officers necessary to the proper administration of a well regulated State government.

The climate of the Territory is exceptionally good. We have conversed with a gentleman just from New York who assures us that all along the Eastern coast, especially in the cities, the heat is very much more oppressive than in any portion of Arizona. Then, its mineral wealth is exhaustless; its mountains teem with precious metals inviting capital and enterprise to invest in and develop their immense riches. Labor is remunerative, speculation may be indulged with reasonable assurance of profitable returns, and all branches of business, pursued in a business-like manner, yield an adequate compensation.

It is not, therefore, too much to say that Arizona will very soon be in condition to apply for admission, and claim her right to shine out on the folds of the national flag, a sister State.

YOUNG LADIES' SCHOOL.—The favorably known Young Ladies' School, 1036 Valencia street, S. F., is this year certainly well prepared to do good educational work. The faculty has been enriched by the accession of Rev. Ewd. B. Church, and wife, lately of St. Matthew's Hall, San Mateo, and thus the hands of Miss Cochran, the well known principal of the school are strengthened for the coming year. As the school has three departments—primary, intermediate and academic—it provides for pupils in all stages of advancement; while a full corps of assistants in special studies, enables a young lady to complete her education in any desired line under the most favorable circumstances. For children this school furnishes a thorough training in the rudiments of knowledge and practice, special attention being given to the reading, writing, and speaking of the English language correctly. In no case will other studies be allowed to interfere with these essentials. The advertisement of the institution may be found in another column.

USEFUL FOR WHOOPING COUGH.—The vapor of oil of turpentine is said to be very useful in whooping cough. The oil may be placed on plates in the patient's room.

## Possibilities of Cast Iron.

The term "castiron" suggests, at once, masses of the metal of considerable weight, and whatever the form. We are accustomed to see cast iron in forms difficult to produce by forging processes, and hearing a relation to wrought iron similar to that of the heavy timbers of a building to its joinder work, or the frame of a structure to its attachments.

There is a class of cast iron work that formerly was imported more extensively than now, which gave us minute articles of use, and even ornamental appendages to dress, so light in weight and so apparently fragile in form as to suggest fine hand labor. It was once supposed that we had no material or means to reproduce such diminutive and fragile articles from cast iron. But recent improvements, both in material and manipulation, prove that we can almost equal the delicacy of what is known as "Berlin iron."

Fine charcoal iron possesses wonderful properties of fluidity when in a molten state. It finds its way into the smallest interstices of the mold and comes out cooled, a definite reproduction of the imprint of the pattern. So exact is this reproduction that bare lines, to be represented only by very fine wire in diameter, come from the mold perfect in form and quite tenacious in texture. Articles of cast iron, cast in a mold of sand, which require fifty or a hundred to balance a quarter-pound weight, are as readily produced here as articles weighing pounds, and much more readily than those weighing proportions of tons.

It may be doubted if any metal is capable of producing more diminutive objects than iron. Lead has been used in making filmy ornaments and toys, being cast, while in an almost boiling state, into hard metal molds, which were instantly compressed to expel the superabundant metal; but the same trick is possible with iron, but is not made a business, because films of iron would crumble almost at a touch. Still the iron is there, and is capable of the fluidity of lead, even if it does not possess its tenacity when cold.

As instances of the possibilities of charcoal iron in casting, let anyone examine the delicate shoe buckles and belt buckles, the shawl clasps and ornamental hairpins called steel, which bear a furnished surface rivaling that of silver. He will find that they are of cast iron, very brittle, and showing a bright iron fracture. Millions of these articles are made in this country, and they are cast in sand molds, just the same as masses of iron are cast; and they come out as perfect—more perfect—than the heavier castings.

In short, the possibilities of cast iron range from the utmost capacity of adjoining cupolas, capable of melting 30 tons, to the hand-ladle that with 10 lbs. of metal pours forth a thousand separate articles.—Boston Journal of Commerce.

## The Corrosion of Iron and Steel.

At a meeting of the Iron and Steel Institute, held recently in London, Mr. Parker read a paper on the "Relative Corrosion of Iron and Steel," which we copy from Engineering. Mr. Parker gave a description of tests which he made on discs, 4½ inches in diameter, by ¼ inch thick, of iron and steel plates of various makes and qualities. Seven varieties of iron and four of steel were experimented on, 12 discs from each brand being used, of which six were turned right all over, and six only turned at the edges, the scale being kept as intact as possible. They were accurately weighed and divided into six series, each containing 22 discs, and they were strung together on a rod covered with a glass tube, glass ferrules being also placed between each disc to prevent contact, and thus insure the absence of any galvanic action due to contact.

One series was hung up on the roof of a London building, a second was placed under water at the Brighton pier, a third was fastened under the engine-room floor of a vessel trading to the East, so as to be continuously exposed to the action of the bilge water; and the remaining three sets were hung about 12 inches below the water level in marine boilers of vessels, the two first of which traded to India (one having zinc used in her boilers), while the third vessel ran between London and Newcastle. On the completion of the trials, the discs were carefully cleaned by scraping and brushing, and were reweighed, the results being tabulated, from which it appeared that the corrosion of the steel is but very slightly greater than that of the iron. The author concluded by stating that he did not consider undue importance should be attached to any experiments of the kind made on a small scale, and that the most they could be expected to do was to indicate tendencies, and perhaps suggest remedies and precautions earlier than actual experience, which would take some years to accumulate.—Boston Journal of Commerce.

GLOBULAR LIGHTNING.—M. Treclat has described a remarkable phenomenon, of the nature of globular lightning, observed by him during a thunderstorm last August. A very bright ball, somewhat elongated, passed out of a dark cloud and into it at another place; but, just before disappearing, it gave off a little of its substance, which fell vertically, like a body having weight. The falling body, which left a luminous track, divided, and was extinguished a little above the tops of the houses.

# GIANT POWDER,

Manufactured under Alfred Nobels' original and only valid Patents for Nitro-Glycerine Powders, which has been and still is of such immense advantage to the Miner, Railroad man and the Engineer. All other Nitro-Glycerine compounds, for instance, so-called Hercules, Vulcan, Vigorit, etc., are simply imitations and adulterations of the original Giant Powder.

## The GIANT POWDER Company

Manufacture three Grades of Powder, which are the

**SAFEST AND STRONGEST HIGH EXPLOSIVES IN THE MARKET.**

THE ORIGINAL NITRO-GLYCERINE COMPOUND

# GIANT POWDER

= O R =

# DYNAMITE

Is acknowledged by all the great Chemists of the world as unapproached by any other compounds, no matter under what names they may have been placed before the public, for instance, all Chlorate of Potash and Gun Cotton mixtures have been thoroughly tested and tried in Europe, and abandoned on account of their liability to spontaneous explosions.

---

## The Judson Powder

Is a Black Powder owned and Manufactured by the

## GIANT POWDER COMPANY,

It is from **Three to Five times Stronger than ordinary** blasting Powder, and is used by all the **Railroads and Gravel Claims**, as it

**Breaks More Ground, Pulverizes Better and Saves Time and Money.**

It has therefore superseded the Ordinary Powder wherever tried.

TRIPLE FORCE CAPS AND ALL GRADES OF FUSE FOR SALE.

## Arizona Agriculture.

(Written for the Press)

EDITORS PRESS:—"I do remember my faults this day," as Pharaoh's butler said when the king's dream could not be interpreted. He had promised to remember Joseph to do him a good turn, "but forgot him," and that for two years. It has been nearly two years since I have written anything for the Press, though I have not forgotten it meantime. For, although your paper might not be supposed to have the same interest for me as when I owned lands in California, its weekly visits give me great interest still. I think such a paper grows on one. It seems like an old friend one does not wish to lose.

The mines here, some of them very rich, are continually written up; so my duty will be to report of agricultural matters.

## Climate.

Which is not in every respect the pleasantest in the world all this year round. There are four or five months of quite warm weather. This is rather dreaded by most people, but to me it is not very unpleasant, as there is no sultriness about it, and indoors in daytime and outdoors at night, I rather enjoy it.

Last year, at Tucson, I found my pretty warm; June hot, with remarkable electric phenomena. Leaving my cot with the clothing on it in the sun by day, on first moving the clothing on going to bed in the dark, a faint but distinct sparkling would be seen all over the sheets. Horses, dogs and cats sparkle on stroking them with the hand, as though they were ready to take fire. It seems as though the earth on becoming dry is filled with electricity, which is not able to become equalized till in July, when the rains come. Then there is more lightning and thunder in a small rain cloud than anywhere in the world, perhaps. I never saw such grand and peculiar display of lightning anywhere in the Eastern States, or even on the west coast of Africa. There are not many so-called accidents by it. One man in Tucson was killed year before last.

But the most of July last year, was exceedingly pleasant; cloudy and only moderately warm, so that riding was exquisite, and even working in the fields was delightful.

The rains cease mostly in August, when, as the sun blazes down again, it is hot, particularly when exposed. In the latter part of September the nights begin to get cool, and by the last of October there is, some years, frost. It is frosty some in November; more so in December, so that some nights ice forms an inch thick. The present winter we have not had a speck of snow, but a year ago there fell, on the night of the 29th of January, seven inches of snow—a very rare occurrence here—so that next morning it was considered fun for the ladies and gentlemen to snowball and wash each other's faces at a round rats. It is generally warm by day, so that snow soon leaves, except on the higher mountains. The present winter we have had two pretty fair thunder showers and a sprinkle or two besides, which laid the dust.

## Agriculture.

The trouble is, there is not half enough rain to produce crops. None can be raised without irrigation. Even with irrigation it takes great care and watchfulness to preserve crops through the hot weather. Secondly, soil and productions.

Around Tucson it is not so good an agricultural country as on Gila and Salt rivers. Good wheat and barley are raised where there is water; but Salt river carries off the palm for vegetables generally. Near Phoenix, nearly everything does well. Fine Irish and sweet potatoes are grown, with melons and fruits, which is not the case here. There are but few localities here where a good watermelon can be found. The difficulty with them arises from multitudes of insects (*aphide*), which settle on the vines (riss out of the ground, I am told), in inconceivable numbers, so that the leaves are consumed. The droppings from them look as though grease had been poured over the soil. Hence the Mexicans give it the name, *Manteque*. This takes place just as the fruit is nearly grown, so that the melon, deprived of the sustenance of the leaves, lies there in the sun, saddens and sickens; and is not fit to eat.

On the rich sandy soil of the San Pedro, the Gila, and especially the Salt river, there seems to be no such trouble. Hence they have delicious watermelons.

The muskmelon is not so troubled, and with good seed very fine ones are raised. But it seems to me to come from genial California, very difficult to raise anything here. Possibly one may get skillful enough to meet all difficulties after a time, but it has often worried people out in trying.

In this vicinity, just as grapes and peaches come to ripening, thousands of large, green bugs, of the beetle kind arrive, and proceed as though the whole crop was grown for them exclusively, and I really believe they would swallow down 100 acres of grapes inside of a month if let alone. I judge thus from the manner they attack a half acre of them. People, therefore, have not attempted here to raise any large sized vineyards, for the only way to save the grapes is to tie a paper bag over each bunch. Then, it is true, the grapes become delicious, and very early too, so that the crop is

gone before California grapes begin to come in. They sell readily at 25 cents a pound.

It is not so bad with peaches, though they eat many of them. If peaches here could be early enough to be ripe before the bugs come, or ripen after the bugs are gone, there would be "big" money in peaches. If I could make up my mind to settle permanently here, I would plant the early and late varieties, with the apricot, which it seems now will sell for years at a high price, from 25 cents a pound down to 10 cents. If one could raise half enough to supply the market of Tucson alone, he would have a fortune if he could get only what the freight charges would be on fruit from California. And peaches and apricots grow and bear well here. I have eaten as fine peaches from the tree here, as I ever tasted, I think.

There is sometimes a difficulty, by the fruit being killed; the weather becoming so warm, (as it was this year), in February or March, that the leaves and blossoms are forced out, and then if late frosts follow the fruit is cut off. Apples and peaches do not seem to thrive. It may be that plums and cherries may bear. This will soon be tested. But I must defer till next time.

H. H. MESSENGER,

Tucson, Arizona.

## To Regulate Chloridizing Roasting of Ore.

The main points which have to be considered at a chloridizing roasting are: The time of roasting, the temperature, the amount of salt and the loss of silver, all with reference to the percentage of chloride of silver. The first thing necessary to know, is the amount of silver contained in the ore—for this purpose a reliable average sample must be taken, including this salt if already mixed; this sample to be No. 1. It must be taken either while it is charged in the furnace, or at the battery every 10 or 15 minutes while it drops from the sieves. The roasting should be carried on at a moderate heat. After three or four hours, when the ore assumes a woolly condition, other samples are taken from different parts of the furnace, mixed together, and the assay sample therefrom marked No. 2. One hour later a third sample is taken, No. 3; half an hour after this, No. 4, and before the discharge, or during the discharge, No. 5. The temperature of the last hour should be a moderate light red heat. In case there is a double or treble hearth furnace, one sample more should be taken from the hearth next to the finishing hearth, just before moving the charge over to the finishing hearth, but as there are three charges on three hearths, the samples have to be taken of one charge as it progresses from one hearth to the other.

While the next charge is treated in the same way, but a higher heat applied, the samples already taken must be assayed. In order to find the progress of chlorination, the assay of No. 1 is not needed, it serves only to ascertain the loss of silver during the roasting. One assay of No. 1, however, would not be sufficient, because the weight of the ore changes. For instance, the iron sulphuret (pyrites) loses its sulphur, which is replaced by the lighter oxygen, and weighs then 33% less, but in taking up chlorine, in place of the oxygen, it gets much heavier than it was when a sulphuret, gaining 35%, but a great deal of the chloride of iron volatilizes. For this reason two assays of No. 1 are weighed out, one to be assayed in the usual way, to find out the amount of silver per ton, and the other half ounce is subjected to roasting under the muffle, in a roasting cup for one hour and a half or two, at about the same heat as in the furnace, then weighed out and noted how many grains were lost or gained, as compared with the original 240 grains.

The other samples are assayed to ascertain how much of the silver was chloridized. If, then, all the assay samples showed a progress in chlorination, so that No. 5 was the highest, but still not satisfactory, it indicates that either the time was too short, or the heat too low, or perhaps not enough salt; these assays show also the relative loss of silver.

While these assays were made, the next charge, as before mentioned, was to be conducted at a somewhat increased heat, and samples taken as before. If now, for instance, the last two samples should show the same percentage of chlorination, it were evident that the roasting was carried on too long. In case the chlorination were still too low, and the last one the highest, then the roasting should be tried one hour longer—eventually more heat or more salt, but always controlled by assays. Such investigation may take two or three days, or more.

To ascertain the loss of silver, an average sample is taken when the roasting is finished, and for an assay, weigh out, not half an ounce, but so many grains as there were found after roasting of No. 1 under the muffle, and this weight considered as half an ounce. If then, for instance, the first assay of No. 1 should give 83 ozs. per ton, and that of the roasted ore 73, that is 5 ozs. less, the loss of silver by roasting would be  $\frac{5 \times 100}{83} = 6\%$ .

The loss can be considerably diminished by a proper arrangement of sufficient dust chambers, in which also the volatile metals could be condensed.—*Kustel's Roasting of Gold and Silver Ores.*

"ARE sisters Sally and Nancy resources, pa?" "No, my boy; why do you ask that question?" "Because I heard Uncle Joe say that if you would only husband your resources, you would get along a great deal better than you do. That's all, pa."

## Sinaloa and Durango.

Under the auspices of some of Boston's prominent bankers and business men, for the purpose of development of Mexico and securing the profitable advantages offered by the Mexican government in her concessions for the securing of the construction of lines of railway and telegraph, the Sinaloa and Durango Railroad Company, (Limited), has been organized under the general railroad act of Massachusetts, of which Mr. Thomas N. Hart is president, and Mr. S. W. Richardson, of the banking firm of Richardson, Hill & Company, is treasurer. The company, having secured one of the most valuable concessions made by the Mexican government, are now receiving subscriptions; and in the proposal an opportunity for investment is given which is not often offered upon such advantageous terms. For \$2,700 cash, payable as the same may be assessed by the board of directors, but not more than 20% in any one month, the company will deliver to the subscribers twenty shares of the capital stock at par, \$1,000 in income bonds and \$3,000 in first mortgage bonds. Subscriptions may be made in sums of \$2,700 or in multiples thereof. This company has secured the concession from the Federal government of the republic of Mexico, celebrated August 16, 1880, between Manuel Fernandez, Chief Clerk of the Department of Public Works, representing the executive of this Union, and Senator Mariano Martinez de Castro, representing the government of the State of Sinaloa, authorizing the construction of a railroad and telegraph line in that State, between the Pacific seaport of Altata and the city of Culican, with the privilege of extension into the State of Durango, to reach the city of the same name, or to any other point in the State where it can connect with the line of inter-oceanic or national railway which is to pass through that place. Under the grant and among the concessions to the company are exemption from all taxes and imposts, for a period of 20 years, on its property, including the capital employed in the construction of the road; exemption from all duties on all materials necessary for the construction and operation of the railroad, including locomotives and rolling stock, and for the necessary repairs of the same, for a period of 20 years; the right of way, 70 meters—278 ft.—in width, the entire length of the railway; the public domain, which the line may occupy in the extension fixed, and the lines necessary for stations, warehouses and other buildings, as well as for the water stations and other indispensable accessories of the road and its appurtenances, if the property of the nation shall be given without compensation; the ore beds, also those of coal and salt. The marble and other mineral deposits encountered in the works and excavations made upon the line of the road and its branches, shall be the property of the company, without prejudice to the rights of others, provided it claims and works them subject in all respects to the mining laws, and also a subsidy of \$9,000 per kilometer, or at the rate of \$14,484 per mile, to be paid to the company by the general federal treasury. The estimated cost of constructing this railroad and telegraphic line from Altata to Culican, a distance of 40 miles, is \$500,000, and to either Corsala or Tamazula, as the surveys may determine, 40 miles further, \$500,000 more. The area of the State of Sinaloa is 185,200 square leagues, and its population 162,587, equal to 31 inhabitants to each square league. This State, according to existing political division, contains the capital, Culican, which is the seat of the Legislature, the Supreme Court, the Governor and the Federal authorities. It has nine districts, in the principal towns of which there are political prefects, 31 municipalities, 91 villages, 515 hamlets, four cities and nine towns. There are 114 mining districts, with 400 opened mines of silver, gold, copper and lead; 50 reduction works and 9 deposits of salt; 1,229 haciendas, cattle ranches and cultivated farms. The States of Sinaloa and Durango are now producing between \$4,000,000 and \$5,000,000 of gold and silver per annum, and the production is now on the increase. The American processes of reduction are almost exclusively in use, the mills being built in San Francisco. As a considerable part of the ore mined is rich, large quantities are carried on mule back to the coast and shipped to European ports in a raw state and also as concentrations.—*Economist.*

MINE MANAGEMENT.—John O. Earl has commenced an action against Edwin R. Burke and others, to compel an accounting of moneys received by defendants from the Sumner Gold and Silver Mine, and from the property of the corporation managing it, and the payment of a company note for \$20,000, and to obtain an injunction restraining defendants from disposing of 60,000 shares of pledged stock, given as security for the note. Judge Wilson has ordered that the injunction issue as prayed for. It is averred that the condition of the mine is known to only a few persons, for the reason that the defendants do not permit strangers to visit it; that the financial condition of the company is very bad. Plaintiff says that he is willing to pay the money found to be due on the pledged stock, and charges that defendants have already sold 59,950 pledged shares within the past two weeks for \$135, and would have sold the 60,000 shares for a like nominal sum had they not been enjoined from so doing.

## Copper in Arizona.

A correspondent of the *Bulletin*, writing recently from Tucson, has the following: The copper interests of the Territory are attracting great attention at present, and good copper mines and prospects are eagerly sought after by our resident capitalists as well as by strangers in our gates. The famous Copper Queen mine of Bisbee, which bears the same relation to copper mines that the Contention mine of Tombstone bears to the silver mines, has paid its fortunate owners, Messrs. W. H. Martin & Co., of San Francisco, the well-known seaway contractors, the handsome dividend of \$100,000 per month for the past four months. A recent careful examination of the mine made by John R. James of Tucson, a recognized authority on copper, shows that \$1,925,000 are in sight, estimating copper at 19 cents per pound. The original cost of this mine was \$30,000. A furnace was erected at a cost of \$11,000, making the total cost of mine and plant fall inside of \$50,000. The success of the Copper Queen has stimulated the development of copper properties in other sections of the Territory, and scarcely a day passes without reports of new strikes and big finds of this most valuable metal. The latest transfer of copper properties was made recently, to Mr. Christopher and other California capitalists, by O. A. Hyatt and others of the Apache, Midas and St. Nicholas mines, lying on the easterly slopes of the Santa Catalina mountains, and situated about 55 miles from Tucson. The mines have an elevation of about 7,500 ft., and the vein lies between limestone and porphyry, the limestone being the overlying formation. The ores are found in the shape of carbonates and sulphurets, the carbonates predominating. The average assays show 30% in copper, and about \$20 in silver per ton. On the Apache location a crosscut has now penetrated this vein for 15 ft. in ore of the above description, and the hanging wall of the vein has not yet been encountered. The ledge has been uncovered on the surface for 60 ft., and has been traced the whole length of the claim, 1,500 ft. Some specimens of copper ore taken from the cut, assay as high as 70%. The Midas and St. Nicholas claims are extensions of the Apache, and show the same characteristics. Charcoal is abundant, and can be furnished for 15 cents per bushel. Water rights have been secured, and the cost of smelting should not exceed \$10 per ton. As 30% copper ore is worth about \$60 per ton, there is a large margin of profit in smelting the ores on the ground. Yellow pine abounds, and this variety of timber makes the best charcoal known to the smelter. The climate is good all the year round. A good road can be constructed from the railroad tracks to the mines at an expense not to exceed \$3,000. The ores are free smelting, and there seems to be no reason why the successes of Bisbee should not be repeated at an early day in the Santa Catalinas.

There seems to be a disposition in some quarters to discourage copper mining in Arizona and mysterious hints are thrown out and circulated here in Tucson by certain Boston gentlemen to the effect, that the Calumet and Hecla mines of the Lake Superior region can produce enough copper to supply the demand in the United States. Of course, it is perfectly natural that said company should desire to retain the vast monopoly it has enjoyed for years, and which has enabled it to pay \$18,000,000 in dividends, but the claim of its friends and stockholders that it can supply the American market is preposterous and without foundation. The consumption of copper in the United States amounts to about 25,000 tons per annum, and the consumption is increasing, owing to the new and various uses to which this metal is applied. The Calumet and Hecla produces about 600 tons a month, not one-third of the annual demand. Besides its ores, it averages only three per cent in copper, and has to pass through the process of crushing, concentrating and smelting before ready for market. In our Arizona mines where carbonates abound, the rudest kind of furnace is sufficient to work the ores and convert them into marketable copper. With the construction of the Guaymas railroad our producers will be able to ship from Guaymas direct to foreign ports, and will compete successfully with Chile in supplying the English demands which amounts to about 40,000 tons per annum. The future of the Arizona copper mines is bright and full of promise, and now that avenues of transportation are open by which products can reach tide-water, we ought to be able to under-sell every other copper country.

A BIG RAILROAD SUIT.—The largest railroad suit which ever came before the courts of the United States has just been commenced at Santa Fe, N. M. It is between the Texas-Pacific and Southern Pacific railroads of New Mexico. The suit is brought to recover all that portion of the Southern Pacific built upon the land grant of the Texas-Pacific in New Mexico, which is over a district of country from Sanson river, on the Arizona line, to within four miles of El Paso, a tract of 130 miles. A temporary injunction has been granted, restraining the Southern Pacific of New Mexico from using, occupying or running the road within the limits of land of the Texas-Pacific, or on its right of way in New Mexico, and Judge S. B. Newcomb of Lawrence has been appointed temporary receiver. This suit has been brought since Jay Gould was elected to the Presidency of the Texas-Pacific. This is probably the first shot in a big railroad war.

# Descriptive List of Spring Wagons

—MANUFACTURED BY THE—

## SWEEPSTAKE PLOW COMPANY,

COMPRISING AMONG OTHERS THEIR STANDARD MAKE,  
No. 0, No. 00, No. 3 and No. 9,

Which they keep in Stock. The increasing demand and popularity of these Wagons, warrants us in calling for them a superiority over all others in the market. They are stylish, easy running, durable and first-class throughout, made by skilled mechanics, using best quality of timber throughout; thoroughly seasoned and standard grade of wheels; all passed through boiling oil and placed in the dry house until ready for use, thereby enabling these Wagons to withstand the hot climate of the interior of our state, and the parching heat of the San Joaquin and other valleys. The iron work is of the best of material. Springs made to order of Swedes steel, Oil Tempered and Warranted. Axles solid collar and faulstaid—made for these wagons only; with patent wrought iron case-hardened boxes, indestructible, and which will not wear out and can not break; the best and most expensive and durable axle box which has ever been brought into use. The painting is neat, not excelled anywhere; and trimmings stylish. In fact the Wagons are all that can be asked for in quality of material, workmanship, general proportions and finish, while their immense sale is convincing proof that they are reasonable in price, and are appreciated by all those who have used them and who believe in the old adage "The Best is the Cheapest."

NO. 0.—WITH POLE AND BRAKE

No. 00 is a light Side-Spring Wagon—or Buggy—put up with our Patent Equalizing Rods, which causes the body to set level when unevenly loaded; that is when the load is upon one side, the body will remain level, and not tip sideways, as is common with side springs. It also makes it ride much easier. Its price makes it popular as a Business Wagon as well as a Buggy. It being light, stylish and neatly painted.

Axle, 1-inch.  
Springs, 1½ inch, 4 leaves.

NO. 00.—WITH PATENT EQUALIZING RODS

NO. 1.— WITH POLE AND BRAKE.

No. 1, with Top, is a popular Family Wagon and Carriage, and is of the same mechanical construction, style and finish as No. 1 without Top. It is a neat standing Top, with drop curtain; is nicely trimmed and handsomely painted. The Top can be quickly removed if desired, and an open Wagon, made of it. It takes the place of a more costly vehicle, and supplies a want long felt for a stylish cheap Carriage.

Axle, 1½ inch.

Springs same size as used on No. 1.

NO. 1.—WITH TOP.

NO. 3.—WITH POLE AND BRAKE.

No. 3 is built very much on the style of our No. 1 Wagon, 4 springs, but has 1½ inch axles and heavier springs; intended for heavy work and loads; has a drop tail board and good length of body, while the seats are easily removed. It is used as a Grocery and Express Wagon; and for farmers who require a Wagon for family use and farm purposes, we can highly recommend it.

It is also made with Top, as shown in No. 1, or a cheaper Top, if desired.

NO. 4.—PLATFORM GROCERY WAGON.

No. 4 is made only to order. Is intended for a Grocery Wagon, and is an elegant and well-made vehicle and well adapted for that purpose.

The wheels turn under the body like those of a hack, thus enabling it to turn in a confined space. It has become very popular; is in every way complete. It has only to be seen to be appreciated. Nothing better in its line can be found.

NO. 7.—PLATFORM SPRING WAGON.

No. 7, Platform Spring Wagon, as shown in cut, is designed for Farmers, Hucksters and Fruit Growers, and for a Light Passenger Wagon. Having six long springs, they give an ease of motion to the body, while the bearings are near the hub, instead of the center. The wagon is well adapted for pleasure riding, and carrying small fruits over rough roads, and for general use is the best and most desirable Spring Wagon which we make. There is no woodwork to the gear, no reaches to break, and they are destined to become the most popular Spring Wagon on this coast for general use. We guarantee those Wagons to be all that we claim for them, and invite the particular attention of our patrons to our Platform Wagon. It is perfect in mechanical construction, unlike many imported from the East, which have proved a failure. They are made with axles from 1½ to any size required. Our popular size, shown in cut, 1½ inch axle. At present we manufacture No. 7 only on direct orders.

NO. 9.—HILL'S PATENT BUCKBOARD.

With a combination of Steel and Wood Springs, is stylish, light and easy running; nice for business or pleasure. The Hill's Patent Buckboard is rapidly coming into favor on account of its combining all the essential points required in style, shape and workmanship. The flexibility of the Steel Springs, combined with that of the wooden side bars, secures an ease in motion not heretofore attained in Buckboards.

No. 10 is a 4 Spring Grocery and light Business Wagon, 1½ inch Axle, Shafts, Brake and one Seat. We make the seat on direct orders, either movable or stationary, foot board, no dash. It has the same running Gear as shown in cut of our No. 1 Wagon, and is adapted for all kinds of light work, and can be used with two seats when desired.

No. 11 is 1½ inch axle, Thoroughbrace, 2-seat canvas trimmed, with canvas top—same style of body as No. Wagon. No material difference except in trimming and Thoroughbraces. Can be used with one seat. We build them for the Arizona trade. They make a fine Express or Road Wagon, etc. Suitable for Tourists and Surveying Parties. Have some now under way.

This Company will also build to order Spring and Thoroughbrace Wagons of any description desired. Send for Catalogue and Price List. Address Agents, BAKER & HAMILTON, San Francisco and Sacramento, or Manufacturer at San Leandro, until July 15, 1881, after which at BENICIA, SOLANO CO., CAL., as it is proposed to Change the location of the Company's Works to Benicia in July next.

### The Wood River Mines.

[From our Special Traveling Correspondent.]

The first mine discovered in the Wood River country was the Big Camas mine, located by M. H. Williams, W. H. Spencer, David Whitmer and Ross Smith, in the fall of 1864. This mine is situated about nine miles due west of the present town of Bellevue, and, unlike most of the more recent discoveries, carries free gold and silver. Work on it was begun in 1865, and was continued for about 18 months, during which time a tunnel, 274 ft. in length, was run to tap the ledge. This was accomplished at a depth of 130 ft. below the surface, and developed a solid ore body, 18 ft. wide, assaying throughout \$25 gold and from 6 to 15 ozs. in silver. The ledge proved to be a true fissure, with well defined walls, but, owing to the distance from the inhabited parts of the country, and the great expense of labor and material in those early days, nothing beyond representative work has ever been done in the mine since that time. The last few years having wrought a great change in this section, and made what was formerly an isolated hunting ground for marauding redskins the most thickly populated part of the Territory, the Big Camas mine is destined to become one of the best paying properties in Idaho, as soon as it is taken hold of and fairly opened by men with sufficient means to prosecute the work. There is a natural wagon road up to the mine from the old emigrant road, which can be reached in less than three miles, and sufficient water power to run an 80-stamp mill during the entire year.

The next locations made on Lower Wood river were in August, 1873, when the Keystone and Galena were discovered by John Callahan and Cyrus Hedges. These were high grade galena and carbonate ledges, from 2 to 2½ ft. wide, and assaying about 200 ozs. silver and 40 to 60% lead. On each of them are 25-ft. shafts, out of which considerable ore has been extracted. These two are the pioneer galena discoveries in what is now proving to be the greatest mineral belt on the western slope of the Rocky mountains.

During the month following

#### Several Locations were Made

In the vicinity of these mines, among them the Antelope and Phoenix, located by Matthew Graham, W. H. Spencer and M. H. Williams. But from this time until the fall of 1876, very little attention was paid to Wood River, and only a few new discoveries were placed on record, except on the East fork, which empties into the main stream about four miles below the present town of Ketchum. Then, some locations were made in 1875, by James Wrencher and Isaac Bryan, which have proved to be very valuable. The principal discoveries made by them were the Paymaster and Silver Tide, from which considerable ore was shipped during last season.

#### In the Summer of 1877

The Nez Perce Indians put on the war paint, and the year following came the Bennock war, which prevented anyone from entering this isolated section. Big Camas prairie had always been the

#### Favorite Home of these Tribes,

And its close proximity to the mines rendered prospecting anything but desirable. Thus, the further development of this country was retarded for two years more, but 1879 found the Indians routed and a new era of activity at once began. This was stimulated by the great influx of miners to the Yankee Fork and Salmon River regions, who after prospecting in that country soon found their way down to Wood River. During that year a number of valuable locations were made in this section, notably the Queen of the Hill, discovered by Frank Jacobs; Mammoth, by Matt. Williams & Co.; Oswego, by Isaac Lee; Star, by Zach. Hayes; Julia and Scorpion by Ben Kennedy *et al*; Black Bear, by the Kelley Bros., etc.

During the winter of 1879-80 some miners and one family wintered on

#### Wood River, for the First Time

Since the country's discovery, with the exception of one winter, that of 1865-66, when M. H. Williams and two others ran their tunnel on the Big Camas mine. In the spring of 1880 a big rush began from all quarters, and it is estimated that 3,000 men scoured the mountains, hillsides, canyons and gulches, as if "in search of that which was lost." During that year C. P. Croy discovered the Bullion; A. P. Turner and Thomas Edgington, the Idahoan; Geo and Thos. Edgington, the Mayflower, and Lewis Bros, the Jay Gould. Among other valuable locations made that season may be mentioned the Town View, Monday, Minnie Moore, Climax, Elk Horn, North Star, Penobscot, Relief, Hard Times, Ornament, Meyer's, Chicago, Iris, Garfield, Rippetoe, Orient, Ophir, Jim Blaine, Ritchie, Greenhorn, Lewis and several hundred more. These locations are all on lower Wood River, south of Warm Springs creek and the East Fork; but nearly, if not fully as many discoveries were made in the vicinity of Galena and Saw Tooth City, as well as on Little Wood River and in the Smoky Creek district, all being within the boundaries of Alturas county. The towns of Bellevue, Ketchum, Galena, Bullion and Saw Tooth City saw their beginning during that season, and about 200 families and 1,000 single men decided to brave the cold and snow of last winter in these places. About the 1st of March, this year,

### A New Emigration

From Utah, Nevada, Oregon, and, in fact, all parts of the Pacific Coast, began to pour in, so that now there are fully 500 families and 10,000 men in the same scope of country. Such a stampede as this has never been witnessed since the balmy days of White Pine. The roads are lined with teams, horses, and men on foot. The stages from Blackfoot and Boise City are loaded to their utmost capacity, while the line from Kelton had to "double up," several weeks ago.

Bellevue, which has heretofore been the principal town, has now found a rival in the promising city of Hailey, situated five miles higher up the river. This place is only seven weeks old, but has already over 200 buildings, which keep increasing at the rate of ten per day. There is a great race for supremacy between the

#### Two Towns,

And considerable jealousy between their inhabitants. This is heightened by the intended change in the location of the county seat, which is now at Rocky Bar. Both places contend for it. Bellevue people refer to Hailey as the "Mushroom City," and the Haileites retaliate by speaking of it as "the place at the mouth of Slaughter House gulch, commonly known as Bung-hole, but designated by the Postoffice Department as Bellevue."

I am not yet prepared to venture an opinion as to which will become the main town, but as far as indications go, Hailey seems to have the advantage in many respects. It is beautifully situated on the east bank of the river, directly opposite Croy's gulch, in which all the best mines have been discovered, and has the natural location for a future city and place of supplies.

A. L. M.

### A Mining Romance.

A year ago an American prospector of the better sort, understanding Spanish thoroughly, while looking over the archives of an old church near Magdalena, Sonora, discovered a manuscript report of a Jesuit priest who traveled over Arizona more than one hundred years ago. The brave missionary, in the cause of Christ and in the interest of Spain, had traversed deserts, forded rivers, crossed mountains and battled with Indians. He was finely educated, particularly in mineralogy and geology. In the course of his travels he discovered rich mines, some of which he developed, and all of which he described. The manuscript describes the Silver King mine, and locates it, giving longitude and latitude exactly. It is said to be a mine richer than any yet discovered, but adds that in Sonora there is a mine as far ahead of Silver King as Silver King is ahead of ordinary mines. The longitude and latitude of this mine is given, and the paper adds that when this mine is developed untold wealth will be dug out, and silver will become a drug in the market.

It is also stated that this mine has been somewhat developed, and that the surface indications were surprising. From an examination of the data, Mr. John J. Carrillo, of Los Angeles, was led to hunt for the mine, and he believes he has found it. He finds an old shaft at the exact locality. Large trees have grown up in it, and the dump is covered with vegetation. Ages have elapsed since the miners have been silenced in death. Unceasing vegetation has in a measure obliterated the work, but it is estimated that 3,000 tons of ore, averaging \$100 to the ton, are on the dump. It would be strange if, in this iconoclastic age, an old Jesuit explorer should have left such a record as to unfold the story of untold wealth in a Sonora bonanza for a Californian to enrich himself with. It is to be hoped the religious enthusiast may have contributed his mite toward enriching the present, and that his science may have done something for the progress of the American Republic.

### Magnetic Separation of Ore.

A Belgian company, who work a zinc mine in Spain, met with ore containing a mixture of calamine and spar iron, which they could not separate by any preliminary treatment. They accordingly applied to Siemens and Halske, the eminent electricians, of Berlin, who devised an appliance capable of separating 20 tons of ore daily. It consists of an inclined steel shaft, fitted with an endless screw of brass, and surrounded by a brass tube open at its upper surface. The tube is mounted inside a hollow cylinder composed of a series of parallel iron disks, separated by brass hoops and connected by iron rods. This constitutes a series of magnets, the annular poles of which form the inside of the cylinder; the magnetism being effected by means of insulated wires rolled round inside the hollow cylinder. It is here that the magnetic particles yield to the attraction of the annular magnets, and are carried, by the rotary motion, to the upper portion of the cylindrical surface, until they meet a baffle plate, which deflects them on to the screw. Falling through the slot on the upper surface of the tube, they are carried along by the revolving endless screw, and pass out into a shoot at the end. The particles which are not magnetic slip along the bottom of the hollow cylinder without being attracted by the magnets, and pass out by a separate shoot.

### The Truth About Arizona.

Arizona, in the opinion of many of the people who derive their information from itinerant bums with neither the means pecuniarily or the ability intellectually to form a correct estimate of its capabilities, is a territory made up of burning suns, arid deserts and inaccessible and inhospitable mountains. They may believe, and probably do, that the mountains are pregnant of gold and silver, iron, copper and other precious metals and ores, but at the same time they cannot be utilized because of the intense heat, the unhealthiness of the climate, scarcity of water, the inaccessibility of the deposits, etc. Now, to those who have resided in the Territory for any length of time and made themselves familiar with its resources, and possibilities, and general condition, climatic and otherwise, all these statements are the sheerest nonsense. Such a one is the editor of the *Journal*, of Tucson, and he says: "Nobody pretends to say that the climate is that of Italy represented by the poets; that its agricultural productions are as luxuriant as those produced in the prolific valley of the Mississippi; that its flora is as beautiful as that of Florida, or its fauna diversified as that of the jungles of Africa give to zoology, or, perhaps, that its mineral wealth is as great as the boasted riches of Ophir and Golconda, but we do pretend to assert and maintain that it is no such repulsive locality as it is represented to be by ignorant and uninformed charlatans. There are mountains, but they are rich and accessible; there are plains, denuded of herbage, but they are susceptible of high cultivation and prolific of vegetable productions; water, though scarce in some sections of the Territory, may be found abundantly in others; the range of the mercury during a few of the summer months may be high, but the heat is not of that oppressive character which prevails in other States and Territories and renders a residence therein at once disagreeable and dangerous. In short, we dare to reiterate that Arizona offers as many inducements for permanent settlement, if not more, than any territory acquired by the United States within the past quarter of a century.

To active enterprise, a vast and profitable field is opened. In mineral wealth it is outstripping the vaunted supremacy of the Comstock, and with the single exception of Colorado, bids fair to lead in the van of silver-producing countries. What it is capable of in an agricultural way remains as yet, of course, an unsolved problem. Other industries have oversleighted agricultural pursuits, and must necessarily continue to do so while the former offer to the speculator and adventurer prospects of a more immediate or prospectively profitable return; but as the Territory increases in population, the want and necessities of the inhabitants increase in proportion until, at length, it will be found that other industries and pursuits than that of mining will afford remunerative returns. Then there will also be found persons who will turn their attention to the soil, and if there be, as we believe there is, vitality in it, we will have gardens, fields, ranches, trees, flowers, and fruits, and flowing waters where now all that meets the eye is desolate and barren.

### Columbus District, Nevada.

The Columbus District mines attract a good deal of attention. The mineral-bearing belt is four miles long and two miles wide. It contains two lines of mines, the first beginning at the north, or rather northwest, and runs in the following order: Northern Belle, Princess, Mount Diablo, General Jackson and New England. The second ledge, about 3,000 ft. to the east of the first, has its mines located with the Victor at the north, and George Washington, Mount Potosi and Enterprise adjacent. There is another shorter ledge, on which is located the Metallic, Equator and Lucky Hill. The Northern Belle was the first mine developed, and securing a mill at Columbus, eight and a half miles away, began to pay dividends immediately. It has now paid over 40 dividends, amounting to \$2,000,000. The Mount Diablo, an equally rich mine, began taking out ore, but was unable to secure a mill, and having no water facilities, could not build one. The proprietors, however, went ahead and developed their property, and now have ore enough in sight to keep a 40-stamp mill running two years. The Victor has 50,000 tons of \$40 rock piled on its dumps, and other mines are similarly situated. There is at least \$6,000,000 in sight in ore, and geologists claim that the district may be counted on for \$60,000,000. Messrs. Clatworthy & Sutherland will bring water from Pinshower canyon, in the White mountains. They will lay pipes 23 miles at an expense of \$100,000, and inside of four months will be able to discharge 300,000 gallons of water each 24 hours, with a fall of 800 ft. As soon as the water reaches the district, the Mount Diablo, Lucky Hill, Victor and George Washington mines will erect mills, and a New York company will erect one for custom rock. The above is from the *Carson Appeal*. We are informed, in addition, that the Lucky Hill is owned by well-known San Francisco capitalists, and the ledge is said to be 60 ft. wide, containing ore that will average from \$30 to \$40 per ton. As soon as the water reaches the district the mills will commence to crush, and a new era of legitimate mining will be inaugurated.

### Gas for Roasting Ore.

At a recent meeting of the American Institute of Mining Engineers, W. J. Taylor, of Chester, N. J., read the following paper "On a fluxing gas producer for making heating gas."

In making heating gas with anthracite coal for roasting ore during the past few years, I have tried many forms of gas generators. So far, the most successful and satisfactory one has been what we call a fluxing producer, which is simply a small cupola or blast furnace, in which we charge with the coal, say, 30 or 40% of basic blast-furnace cinder, to units, when melted, with the ash or earthy matter in the coal, and carry it off as cinder. The producer we have in use at Chester, N. J., has more of the lines of a blast furnace than a cupola, the hearth being 24 inches diameter and 24 inches high. It then enlarges on an angle of about 25° from a perpendicular to 4 ft., and then is drawn into 3 ft. on top; total height, 12 ft. We use one water coil-tuyere 12 inches above the bottom, and blow through a 1½-inch nozzle. The depth of coal above the tuyere averages about 6 ft. The producer is blown with a small Weimer blowing engine 24 inches diameter and 12 inches stroke, delivering 6 cubic ft. of air to a revolution, or 300 ft. of air per minute. It consumes, say, 200 pounds of coal per hour, which is about 80 ft. of air for 1 pound of coal. The air pressure is from 1 pound to 1½ pounds to the square inch. The cinder is tapped out about every two hours, and is black and glassy. In this way we get a continuous flow of gas as long as the engine is kept running. We have run for at least four weeks without a moment's stoppage or change of any kind. We depend upon cinder mainly for fluxing, and though we often use a little limestone with it, we have never tried to do without cinder entirely. The only fuel used so far has been anthracite coal, broken or egg sizes giving the best results. We have not been able to make fine anthracite work at all. I have no doubt that almost any kind of bituminous coal could be used, if not too fine.

The advantages in favor of this producer are: 1st. It makes an excellent gas, very uniform in quality. There is so much incandescent fuel above the tuyere that no air can escape unsummed, and the gas is almost entirely free from carbonic acid.

2d. There is no cleaning of ashes to be done, consequently, there is no cessation of the flow of gas and no waste of coal—a very important matter.

3d. The quantity of gas from this producer can be increased by simply increasing the volume of air entering it, and any one familiar with blast-furnace practice can run it, particularly if cinder for fluxing is available. The power required for blowing the producer for burning 200 pounds of coal per hour is, say, 45,000 foot-pounds, or 1½ horse power, which, at 3 pounds coal per horse-power per hour, would amount to 2½% of the coal burned in the producer.

### Idle Mines and the Cause.

In this rich and unequalled mineral country we have several important mining properties lying dormant, and the question is asked upon every corner of our streets, "Why is this?" The answer as given by the *Arizona Miner*, from which we take this item, is a short one and easily given—"Mismanagement."

On the Sandy was discovered the McCrackin. Here we expected to hear of and live to see another Comstock. A mill was put up, ore hauled and crushed, and, naturally, under bad management, came a grand shut down and failure. Finally a careful man, Mr. Hubbard, takes the property in hand without a dollar, pays a royalty on the ore he works, pays for everything and makes money. He manages with economy and good judgment, hence makes a success.

Next we have the Hackberry mill and mine, pronounced a failure. Why is this? San Francisco parties sent down \$30,000 worth of useless machinery, etc., and the small fry who are owners are closed out, being unable to meet their proportion of the indebtedness, and operations cease.

Then we are asked about the Tiger. Here is another piece of bad management. Seventy-five thousand dollars are expended in opening the mine, when really no opening is made.

The Peck, which has yielded hundreds of thousands of dollars, is about to resume operations. This mine, too, has had its bad management in some respects, and serious drawbacks.

The old Vulture, abandoned for years because it could not pay under a foul, bad management, is now clearing \$20,000 to \$30,000 per month.

The Tiptop company has always had good management, and now has in its treasury some \$300,000.

In no instance where judgment and a proper knowledge of mining and milling have been shown in conducting the affairs of any mine in this country, can we call to mind a failure.

MORE COAL.—The last and most important coal find that has been made in Arizona, is in Gila county, and at the mouth of Disappointment valley. It is easily accessible. The wagon road from Globe to Tucson runs past it; 640 acres have been located. The coal is of excellent quality. Steps will be taken shortly to prove the extent and value of the deposits. Among the locators are some of the best men in Globe. The locations are made in the interest of the Arizona Mineral Belt railroad. So says the *Silver Belt*, May 28th.

# PACIFIC IRON WORKS, RANKIN, BRAYTON & CO., San Francisco, California, —BUILDERS OF— MILL AND MINING MACHINERY.

Ore Feeders,  
Ore Crushers,  
Mining Cars,

## CALIFORNIA SUGAR REFINERY.

**FACTORY**—Eighth and Brannan Sts., San Francisco,

**OFFICE**—No. 215 Front St., San Francisco.

—MANUFACTURES THE FOLLOWING GRADES OF—

## SUGAR AND SYRUP.

(A) Patent CUBE SUGAR in Barrels and Bags,

(A) CRUSHED SUGAR,

Extra POWDERED SUGAR in Barrels,

Fine CRUSHED SUGAR in Barrels,

Dry GRANULATED SUGAR in Barrels,

Extra GRANULATED SUGAR in Barrels,

GOLDEN C in Barrels,

EXTRA C in Barrels,

HALF BARREL, 1-4 cent more } For all kinds.  
BOXES, 1-2 cent more }

SYRUP, in Barrels,

Do in Half Barrels,

Do in 5 Gallon Kegs,

Do in Tins, 1 Gallon Each.

All the Products of the CALIFORNIA SUGAR REFINERY are Guaranteed to be Absolutely Pure and free from all Chemicals and other Adulterations.

# HUNTINGTON'S PATENT OSCILLATING STAMP MILL.

This Mill is no Experiment, having been thoroughly tested and Approved by Practical Mill Men.

It consists, essentially, of a bifurcated arm, at the upper end of which is the pitman, for oscillating it back and forth. At the lower end are the shoes, which rest on dies having in closed sides or back pieces. As the arm is oscillated, first one shoe strikes, then the other, alternately. By the peculiar construction a grinding as well as a crushing action is maintained. The shoe strikes and crushes the rock, and then slides along a little, grinding the crushed rock under it. This combines, therefore, the action of the stamp and the arastra. The machine is very simple and economical, being durable and working effectively, and we feel assured will meet a demand long felt. From its peculiar construction, the power required is comparatively light. The most important features of this mill are: First, Simplicity; and the liability to derangement is reduced to the minimum. Second, it is durable, more so than any other mill. Third, it does more work for the given horse-power than any other. Fourth, it is easily and cheaply transported. Fifth, it can be erected in one-fourth the time, and at one-third the cost of the ordinary stamp mill. Sixth, which is most important of all, its peculiar grinding, as well as crushing action, renders it invaluable on gold ores, as it serves to brighten the gold for amalgamations; and, Seventh, the wear of the shoes and dies is uniformly smooth, also, very important. As a gold or silver mill it has no equal.

IT HAS NO STEMS, CAMS, OR TAP-PETS, AND ADJUSTS ITSELF TO THE WEAR OF THE SHOES AND DIES.

For Simplicity, Economy, Durability and Effective Working, it exceeds anything ever presented to the public, and will do the work of Five Stamps with One-fourth the Power.

## PRICES:

900 lb. Hammer, Single Mill, \$500, Weight, 3,000 lbs.	
1,200 lb. " Double " 950, " 6,700 "

# "THE \$1,000 CHALLENGE"

## Ore Feeder for Quartz Mills.

OVER 800 ARE NOW IN USE, GIVING ENTIRE SATISFACTION.

Awarded First Premium at the Tenth and Twelfth Industrial Fairs of the Mechanics' Institute.

Twenty Per Cent. More Ore Crushed with Fifteen Per Cent. Less Wear of Iron than by Hand Feeding.

The accompanying cut illustrates the recently introduced Grip, and also the Spring Attachment, which replaces the Weight heretofore used, and which are obvious improvements.

It is now fully demonstrated, after careful and long continued experimentation and practical use, that the plan upon which a perfect Ore Feeder must be constructed is that of a carrier, and not that of a shaking-table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Jerky or spasmodic contrivances will not answer the purpose for wet or sticky ores.

The Challenge Ore Feeders are now in use in the following Mills, besides many others:

Soulsby.....20 Stamp.....	Tuolumne county, Cal.
Sheep-Ranch.....20 ".....	Calaveras " "
Mahoney.....40 ".....	Amador " "

## Superiority of the "Challenge" Ore Feeder Demonstrated!

At the "Christy" Mill, Utah County, Utah, the "Eclipse" Feeders, (conceived by E. Colman) were introduced, but not carrying a regular supply of ore for the crushing capacity of the stamps, were replaced by the "Challenge" Feeders, which are now running and the stamps crushing forty (40) per cent. more ore than was done by the "Eclipse".

The "Harshaw" or "Hermosa" Mill, of Patagonia District, Arizona, was also originally fitted with "Eclipse" feeders, but after a few weeks' trial they were pronounced adequate to the work, discarded, and the "Challenge" adopted.

The "Silver King" Mill, of Arizona, also removed the "Eclipse" Feeders to give place to the "Challenge".

The "Sole" Mill, of Brown's Valley, Yuba County, Cal., was fitted with "Victor" Feeders, manufactured by E. T. Steen, but proving insufficient, the "Challenge" Feeders were substituted.

Four of the "Victor" Feeders, manufactured by E. T. Steen, were also placed in the "Alexander" Mill, at Grantsville, Nevada, but after a fair trial were discarded, and Hendy's Feeders fitted, and four others of the same pattern added when the second twenty stamps were erected.

These cases are simply cited from among many similar instances, in proof of the vast superiority of the "Challenge" Feeders over all others.

Mr. H. W. GREENWELL, of the Tinsman Mine, El Dorado Co., or any other person can make \$1,000 by disproving the acknowledged superiority of my "CHALLENGE" Feeder, in a competitive trial, side by side, with any other Feeder, on wet or sticky ores from any mine, and I will give \$100 to any one who will procure the acceptance of this challenge, and arrange for a fair and impartial test on merit.

I mean business, Gentlemen, "either put up or shut up."

## JOSHUA HENDY,

Manufacturer of all descriptions of Quartz and Saw Mill Machinery. A Large Stock of both New and Second Hand at Machine Works, Nos. 49 and 51 Fremont Street, San Francisco.

Agent for "BAKERS" Rotary Pressure Blowers.

WIND MILL. One of the best made in this State for sale cheap on easy terms. Address, W. T., care of Dewey & Co., S. F.

## The Old River Beds of the Sierra Nevada of California.

The following is an abstract of a paper written by James J. McGillivray, of Oakland, which he has given us permission to publish:

This subject has been thoroughly investigated by Prof. Whitney as State Geologist, and the results of his investigation embodied in a work entitled "Geology of California; a report of Progress and Synopsis of the Field-work from 1860 to 1864," and later, in a work entitled "The Auriferous Gravels of the Sierra Nevada of California," in which he has discussed particularly the phenomena of the old river beds. The writer has drawn much information from Prof. Whitney's writings, and also from no less eminent authority, Prof. Joseph Le Conte, in his lectures in geology, and in articles contributed by the same gentleman. The most noticeable feature in regard to the old river beds is their great elevation above the present rivers. The region in which this phenomenon presents itself is the place to which we direct our attention. Generally speaking, it embraces the auriferous slate belt of middle California, along the western slope of the Sierra, from Tuolumne on the south to Plumas on the north, a distance of about 250 miles, and from the plains on the west to about 5,000 ft. elevation on the Sierra slope in the east. South of this limit there was but a slight lava flow, and hence the rivers have remained unchanged through tertiary times to the present; while north of this limit the lava flow was so extensive as to completely cover up the old beds and intervening ridges to such an extent that they have been lost sight of; and so with the last two localities we are not here concerned.

### The Ridges.

From the summit of the Sierra there extend in a southwesterly direction a number of gently sloping ridges, on an average more than a thousand ft. above the present canyons. On these high ridges, lying unconformably on the slate, is situated the river-washed gravel of the tertiary, varying in thickness from a few ft. to several hundred. Almost all of the gravel of the old river-beds included in the region under consideration is covered to a greater or less extent by volcanic material. To this has been attributed the displacing of the streams from their former channels. To what extent it was this cause of the displacement will be considered further on.

### The Old and New River Systems.

We have, then, in California, two systems of rivers, the old and the new—the drift of the old system occupying the present divides or ridges, and the present rivers occupying the deep intervening canyons. The direction of the old system was generally parallel to the present. This was naturally the case owing to the direction of the slope of the Sierra being the same in the tertiary as at the present time. The only marked exception to the parallelism of the old and new rivers appears between the Middle Yuba and South Feather rivers. Here the trend of the tertiary rivers is pretty clearly shown to have been in a northerly and southerly direction. In this locality the old system has been cut across by the new. In deciding as to the comparative direction of the old and new rivers we are forced to a conclusion by either one of two arguments. In the first place, the old channels speak for themselves as to the direction of the former rivers; and secondly, geologists almost universally agree that the Sierra was pushed up at the end of the jurassic to at least almost its present condition; that the drift of the old system was deposited during pliocene or early quaternary, and consequently the rivers could not possibly have taken any other direction than that of the slope. The change of direction of the rivers between the South Yuba and North Feather may have been due to an elevation in that part of the Sierra, which changed the slope of the country from a northerly and southerly direction to an easterly and westerly direction.

### Different Views of Geologists.

Views as to the direction of the former rivers have been held differing greatly from the one almost universally held by geologists, as stated above. We will mention two; one because held by a prominent geologist, and the other because of its popularity among the miners at one time. Richthofen, in his essay on "The Natural System of the Volcanic Rocks," says that during the period of volcanic activity in that region the crest of the Sierra was raised at a higher rate than its western foot, and that consequently the ancient rivers which were flowing parallel to that crest have been gradually turned from their channels and made to flow in the present direction of the drainage. As there is no evidence, such as fissures would present, of a general uplift sufficient to cause the change of trend of the rivers at such a recent date, and as the channels filled with gravel from the former direction of the rivers, the theory is untenable.

### Blue Lead Theory.

The "blue lead" theory has for a long time been the hobby of the miners. By it they explained the existence of the blue gravel so universally distributed all over the country. The theory held that the gravel of the blue lead was deposited by a great river flowing for hundreds of miles in a southwesterly direction along the

westerly slope of the Sierra. The theory was founded upon the supposed existence of a belt of deep gravel extending across the country in the direction of the supposed river. It has been shown later, however, that there is no well defined belt extending uninterruptedly across the country. It has also been shown that the deep blue gravel which was supposed to be the kind deposited by this stream was not deposited as blue gravel, but that by subsequent chemical action the gravel became blue.

### Deposition of the Gravel.

We will mention two theories as to the deposition of the gravel, in which has been placed considerable credence: One is that the sea covered the country during the time of accumulation. The objections to this are conclusive: First, no marine fossils have ever been found in the gravel; second, the banks of gravel prove fresh water action. Another theory is that the accumulation of gravel was the direct work of glaciers. The fact that no glacial scorings are found in the gravel disproves this. Whitney believes that there were no glaciers nor ice sheet until the present canyons were cut nearly to their present condition.

### An Anomalous Condition.

The condition of things as to the old and new rivers in California is strikingly anomalous. Instead of the present streams cutting into the old river beds, they were displaced by the lava overflow at the end of the pliocene, and forced to cut new channels. So, as a result, we have the present deep canyons and the old beds left in the high intervening ridges. The condition of things in a typical river bed is quite different: 1. There is no old river bed far deeper and broader than the present. 2. This river bed is filled up with river deposit sometimes several hundred feet. 3. Into this deposit the present shrunken stream is cutting a new channel. Many of these typical beds existed in the same place as at present during the cretaceous and up to the present, as in the case of the Mississippi or Connecticut rivers. At the end of the pliocene, the rivers of the Sierra were displaced by lava and made to seek new channels. The present canyons are the result.

### Geological Features.

Having shown the general features in a comparison of the two systems of rivers in California, we will take up in the order of geological sequence the points particularly bearing on the subject. With reference to the early history of the Sierra, we are not here concerned. We will assume that the mountains were already formed, and begin with the accumulation of the auriferous gravels. First, as regards the original location and condition of the gold, and gravel containing it. The region of gravel deposit is a region of auriferous slates. In Mariposa county, as soon as the slates set in, we find quartz ledges, and overlying the metalliferous slate is the gravel deposit containing gold. It was from the ledges contained in this slate that the gold of the washed gravel was removed. The age of the metalliferous slate is jurassic, while that of Australia and the Ural mountains is silurian. We thus see no connection between gold formation in ledges and geological age as formerly believed. Gold formation is owing to metamorphism and accompanying chemical reaction. That veins are formed in the rocks while they are being metamorphosed by heat is agreed on, and believed, by all geologists. In this connection it is well to note what Whitney says in regard to the time of the formation of gold in the veins of the slate from which the gravel and gold was most certainly removed by the action of water. He says:

"The inquiry naturally suggests itself, then, at what epoch did the formation of the quartz veins in the bed-rock take place? Was it contemporaneous with the grand exhibition of volcanic forces which took place in the Sierra during the latter part of the gravel epoch?—and if so, are the phenomena genetically connected? To the writer's mind it seems clear that both these questions can be answered in the affirmative."

Again he says: "The whole series of phenomena observed in the Sierra Nevada gives ample grounds for the belief that the metamorphic rocks of the range—the bed-rock, in short—were the original home of the gold now so generally distributed through the gravel."

The first quotation from Whitney, in regard to the contemporaneous formation of the gold in the veins and the lava overflow, we are not able to understand. The gold at present found in the gravel was certainly not the gold that was found in the veins during the metamorphism, caused by the heat of the impending lava flood, for that the gold and gravel containing it were placed in their position by the action of water, and that the lava flood was subsequent, need no explanation.

### The Accumulation of the Drift.

As soon as the elevation of the Sierra occurred, at the end of the jurassic, the old rivers ran down the slope in a direction parallel to the present rivers. Then began the accumulation of the drift of the old beds. The conditions must have been very favorable under which the gravel was accumulated in such immense quantities. As an example of the extent of the drift, I will mention that of the Forest Hill divide. The gravel there occupies almost the entire divide from the lower limit of gravel to near the summit of the Sierra, a distance of about 25 miles. The width of this belt of gravel varies from 50 yards to several miles. Its depth varies from a few feet to several hun-

dred. The bedrock over the whole area is comparatively even, as we may imagine the whole slope of the Sierra to have been while the gravel was being deposited, so that the streams were not confined so as to carry off their sediment like the streams of the present canyons. As soon as the streams filled their channels they spread out and deposited somewhere else. In so far as the orography of the country was concerned the conditions were extremely favorable for the accumulation of detritus. Three other things enter as elements in forming deposits. 1. The amount of water flowing in the streams. 2. The amount of erosion. 3. The amount of fall in the streams. As these vary irrespective of one another, we cannot state the exact condition of things in respect to them. It has been supposed that the amount of water in the Sierra was greater than at present to cause the amount of accumulation. There probably was, but it was not necessary for the result. Alternations of drought and freshet would have brought about the same result. The size of the boulders argues a greater amount of water necessary to move them to their present position. On the whole, we prefer to believe that there was a greater amount of water in the streams and a greater amount of erosion, so that the overloaded streams were continually overflowing their banks, until a greater part of the whole slope was covered with gravel. It will be impossible to ever tell how extensive the deposit was, as a great deal has been undermined and carried away while the present canyons were being formed. If we judge from the size of the channels, we conclude that the pliocene streams must have been very large. The deep channel at Iowa Hill, as described by Mr. Goodyear, measures across the top, from rim to rim, over 2,000 ft. The depth of this channel is 200 ft.

### Formation of Present Canyons.

The next event in the history of the old rivers was the displacement of the streams from their former beds and the formation of the present canyons. The cause of the displacement was the filling up and protecting of the old river beds by lava ash and lava. The lava eruption took place at the end of the pliocene. Upon and to a certain extent interstratified with the gravel, there exists deposits of volcanic material—some solid, some fragmentary, and others water-worn, showing that the epoch during which igneous agencies were at work was a long one. As soon as the volcanic period passed away and the streams were left to find new courses, the smallest inequalities helped to decide the ultimate course of the streams, so that it often must have happened that the old river beds were cut into and worn away. To what extent the old river beds have become ridges, and the old ridges become quaternary canyons, it is hard to decide. In this connection, we will say that what has been called the "typical form" of the ancient gravel beds, as seen in Tuolumne Table Mountain, is seldom found. It is of rare occurrence to find the old river-bed followed by a lava stream which has acted as a protecting cap. It will be asked to what extent the lava overflow, in its various forms, has acted as a shield against the erosion of the underlying gravel? To a limited extent only do we think it has so acted. At the time far before the lava eruption there was a slight increase in the altitude of the range which assisted in the cutting of new channels, which have in time become the present deep canyons. After the lava overflow the amount of rain erosion may have been less, owing to the character of the material covering the surface of the country. If the rain erosion was less, the river erosion would be greater, and the streams would soon begin the formation of the present canyons in those places which were the lowest at the particular time, and which were the least protected by the superincumbent lava.

### Age of the Gravel.

As to the age of the gravel we can safely say that it belongs to the last part of the tertiary. Forms of the pliocene are by far the most numerous. Quaternary species are just coming in, and so the lava flow may be considered the closing event of the pliocene and the introduction of the quaternary. As to the existence of man or human implements in the sub-lava drift, there has been nothing thoroughly authenticated, although Whitney believes that man did exist while the gravel was being deposited. He has drawn his inferences from the "Calaveras skull" discovery, which, by most geologists is believed either to have been a hoax; or, if not, it even then ought not to have the significance attached to it which Whitney would give it. If man did exist at that time we have a most anomalous case in evolution, namely: The appearance of man before species long since departed. If man did inhabit the world during the pliocene, he has existed through a period during which several species have come into existence, ruled the earth, and passed away.

OBSERVING THE SUN.—In a letter to *La Nature*, M. Cornillon states that when observing the sun lately with a telescope, he was struck with certain undulatory movements on the disk. On inquiry into their cause he is led to connect them with the wind blowing on the earth's surface at the time. They vary in intensity with this, and they have generally, (but not always) the same direction as the wind. Where they have a different direction they indicate a change of weather, or at least the direction of the wind next day.

## Chlorination Tailings.

However carefully the ore may be treated, a certain portion of gold remains in the tailings, varying, other things being equal, according to the character of the ore. In case this results, in part, from the presence of particles too large to be entirely dissolved, that portion can be extracted by re-treatment, either with gas, by chlorine water, or by amalgamation. But a portion, which is sometimes quite considerable, still remains and resists every mode of chlorination or amalgamation, and can only be extracted by smelting with lead.

In general, it may be said that gold which can be seen by the aid of a lens, after finely grinding and carefully washing a sample of the tailings, can be extracted by chlorination or amalgamation; but that which cannot thus be rendered visible can neither be chlorinated nor amalgamated, even if the ore be re-roasted, with or without re-grinding. (If re-ground it forms a pasty mass, which cannot be leached, being almost impervious to water.) Of course the ore is supposed to be properly roasted in the first instance.

Concentrated sulphides containing gold, and free from lead, will frequently yield as much as 95% of the fire assay, if moderately rich, but the extraction of 95% is considered a good result, from ore containing \$100 worth of gold in a ton. As the material loses about 24% of its weight in the roasting and leaching, it will readily be perceived that if there has been no sensible loss of gold in the roasting, the tailings from such ore will assay about \$6 per ton, and for every hundred tons of ore treated there will be 76 tons of tailings, containing \$456 worth of gold.

Tailings of this character, consisting chiefly of iron peroxide, make an excellent flux for the smelting of galena. All the precious metal they contain is extracted, together with the lead set free from the galena by the action of the iron oxide, and may be considered as clear profit to the smelter, who is obliged to use some kind of iron flux, and can find nothing, unless it be metallic iron, better adapted to his purpose than these tailings. Chlorination tailings can also be utilized in the manufacture of red paint.—*Aaron's Leaching Gold and Silver Ores.*

TELEPHONES FOR LONG CIRCUITS.—It has been found that wires, when employed for a telephone circuit, are much more susceptible to disturbing causes than when employed for transmitting telegraphic signals. It has been observed that the slightest friction, such as will inevitably occur from the ordinary mode of joining telegraph wires, the closing of a pressure screw anywhere on the circuit, the slightest blow upon the wire, vibration from wind, the ordinary modes of support, etc., which produce no perceptible effect on the transmission of telegraph signals, are great hindrances to the transmission of voice vibrations, and thus confine the telephone to comparatively short circuits. It is thought if these hindrances could be avoided, the telephone circuit might be continued to as great a length as the telegraph—even across the ocean. Experiments are now in progress to determine all the facts connected with this matter. These experiments will involve the character, in quality and size, of the wire to be used, the best form of support, and a substitution of soldering the ends together, instead of the usual mode of joining. There is much reason for the belief that the telephone may ultimately as fully supersede the telegraph for long, as it already has for short distances.

REFUGE ROOMS AND BREATHING TUBES FOR MINES.—The invention of Mr. Thomas Harrison, of Sedberg, Yorkshire, is intended for saving the lives of men in mines in case of explosions, fire or floods, and consists in making refuge rooms of boiler plate or other material, these rooms being provided with air-pumps, one pump to supply the room with air through a tube laid under the floor of the mine (to keep the tube from being injured), and connected to an air-shaft or a special blow-hole from surface. The foul air is exhausted by a second air-pump placed in the room, and the foul air is thrown outside and prevented from returning by a stop-valve, or the rooms may be supplied with fresh air from pumps or air compressors above ground. He fits these rooms with double doors, the inner door being provided with india rubber or other material to make an air-tight joint. The second part of the invention consists in laying tubes fitted with breathing taps to different parts of the mines, the said tubes being connected to the refuge room, or otherwise supplied with fresh air, the breathing taps being provided with covers (which may be easily removed) to keep them clean.

THE SULPHUR BUSINESS.—C. D. Rhodes, Supt. of the Humboldt Sulphur Works, at Rabbit Hole, informs the *Silver State* that the company refined 237 tons of brimstone last month, and have inexhaustible quantities of the crude article in sight at their mines. They ship several carloads of it weekly to San Francisco and their grinding works in Alameda county.

THE SILVER KING (Arizona) weekly shipments now run at a rate which will sum up considerably over \$1,000,000 per year, viz: about \$3,000 per day.

### Industrial School for Miners and Mechanics.

[Read before the American Institute of Mining Engineers by OSWALD J. HEINRICH, Principal of the School at Drifton, Luzerne Co., Pa.]

At the Baltimore meeting of the Institute in February, 1879, Mr. Eckley B. Cox, then president of the Institute, called attention in his address to the subject of secondary technical education, and gave an outline of a scheme for a school for boys, which it was intended to start at Drifton, Pa., on the general plan of the Steigerschulen of Germany. This school was first opened on May 7, 1879, when 29 applicants for admission, from 12 to 24 years of age, were examined. Of these 11 were admitted, the others being considered either too young or too deficient in primary education to profit by the instruction. In order that parents might be encouraged to send their children to the public schools, it was thought best not to receive pupils under 15 years of age.

The number in each class is limited to 16, so that each boy may receive proper attention. Of the first class only 8 passed through the full year's course. At the end of the year, on June 29, 1880, a public examination was held with the most gratifying success.

The second year opened on the 1st of September, 1880. Nine candidates were then admitted after examination, and 3 more later in the course; 1 pupil has been dismissed. The school now comprises 19 pupils, 7 in the advanced and 11 in the preparatory class. There is also one boy in attendance at the drawing lesson who is too young for the other classes.

Thus far, the regular instruction has been given only for two hours each evening, Sunday excepted. At times when the pits are closed the pupils are requested to attend during the day from 9 to 12 A. M., and 2 to 5 P. M., the time being occupied in the drawing-room or in solving problems, or in review. If a sufficient number of boys from the regular classes are present, the regular studies are pursued. Attendance during the day is, however, voluntary. The limited, and to some extent uncertain, time devoted to instruction is a disadvantage to the school, but it must be borne in mind that the school is as yet an experiment, and that the boys and their parents have to learn from experience that an education is worth the pecuniary sacrifice which would be involved in working half time and attending a day school.

The interest evinced by the pupils thus far is very gratifying, as is shown in the following figures, expressing their attendance and progress during the first three months of the session:

For attendance—Grades.....	10	9½	9	8½	8	7½	6½	5
Number of Pupils.....	4	3	6	1	3	1	1	1
For Progress—Grades.....	9½	9	8½	8	7			
Number of Pupils.....	1	4	6	5	3			

A grade of 10 signifies "perfect," and 5 "indifferent." The plan of instruction is, in general, as follows:

I. A Preparatory Class.—In this class English branches are taught—spelling, reading, writing, grammar, the elements of composition, arithmetic and geography. An assistant teacher has charge of these branches. Algebra is studied as far as involution and evolution. In teaching geometry, particular stress is laid on the names, properties, and relations of geometrical figures in connection with geometrical construction in drawing. Both free-hand and mechanical drawing are taught with especial regard to developing artistic perception and the power of correct expression. Object lessons are also given to stimulate the reasoning faculties, which we often find but very imperfectly developed. In this preparatory class it is intended to admit boys under 15 years, that they may be well drilled in the elementary branches and better prepared for the next class.

II. The Junior Class.—In this class the English branches are continued, particular attention being paid to composition. The elements of book-keeping are also taught, which serves, by the way, for an exercise in writing and arithmetic. Algebra is continued to equations of the second degree, with one or more unknown quantities, series, and exponential equations, including logarithms.

The boys are also drilled in mental arithmetic and algebra to develop the power of quick perception and decision. The course in geometry is completed, including trigonometry, mensuration, and solid geometry. There is also provided an elementary course in analytical geometry, which is taught as algebraic projection in relation to geometrical projection and mathematical drawing. Geometry is divided into two parts—algebraic and practical geometry. In the first the subject is developed algebraically, with the aid of trigonometrical properties of angles; in the second, the practical applications are seen in the solution of problems and in construction of figures both on the drawing board and in the field. A course in geometrical projection aims to give the pupil facility in drawing any figure in plan, elevation or section which may be called for, both with instruments and free-hand.

In the course of mathematical physics, instruction is given in the elements of natural philosophy. To save time the mechanical portions, as, for instance, the laws of motion, center of gravity, the mechanical forces, etc., are treated mathematically, and the course becomes thus a combination of elementary mechanics and natural philosophy. Where feasible, experimental demonstrations are given.

Chemistry is taught so that the pupils may become acquainted with names, properties, and

combining proportions of the most important elements, particularly with those which enter into the composition of the common minerals. Simple chemical tests for minerals are also taught. The instruction in mineralogy and lithology is confined to the more generally occurring minerals and rocks, and those in which the miner or manufacturer has the most immediate practical interest. In this junior class a thorough knowledge of elementary mathematics and drawing is considered the basis for all subsequent instruction.

III. The Senior Class.—The course of instruction laid out for this class will include the writing of a plain, intelligible report upon some practical subject, either directly from investigation or from memory. This concludes the instruction in English branches. In the drawing-

A NATIVE OF ARIZONA.

room the work will include the elements of construction in wood, stone and metal, making working drawings, and designing simple structures and machinery. Lectures will accompany this course.

The subject of mining will be treated systematically under the following heads:

1. Mining, including,
  1. The useful minerals and metals; their occurrence, and the methods for their exploration.
  2. The various means employed for the extraction of ores, etc.

A NATIVE OF CALIFORNIA.

3. The opening and laying out of mines.
4. The method of exploitation.
5. The maintenance of mines in good order.
6. Transportation.
7. Drainage.
8. Ventilation.
9. Mine surveying and mapping.
10. Accidents in mines, and their prevention.
11. Mining accounts, contracts and estimates.
12. Hygiene of mines, with the remedies to be adopted in case of accident.

II. Preparation of the useful minerals for smelting or for market, which will include the

Americans (9 of Irish descent).....	12
Welsh.....	3
Irish.....	3
Swede.....	2
French.....	1

A noteworthy change is noticed in the pupils with regard to their appearance and dress, which are much improved by their attendance at the school. The effect of the school is also shown in the expressions of regret heard from many young men that they had not entered the school at the start, and some of the foremen deplore the fact that there was not such a school when they were boys. The success of this

THOROUGHBRACE WAGON OF THE SWEEPSTAKE PLOW CO.

machinery used in ore-dressing and in the mechanical preparation of coal.

During the senior year there will be practical exercises in the mine and in the field, which will involve the presentation of reports to the principal.

It is possible that there may be formed a fourth class, to be known as

IV. The Expert Class.—This class will enable pupils and graduates at their leisure to continue their studies with the instructors outside of the regular classes, and thus perfect themselves in certain branches already gone over, or to take up studies not provided for in the course.

It is required that all the pupils must have regular work in the mines or in the shops, and, as far as possible, arrangements are made to accommodate them.

The instruction is entirely free, the pupils providing only their books and materials. Annual public examinations take place and prizes are awarded to the best scholars.

The school-rooms are in Cross Creek hall, a large building 106x51½ ft., having a basement room 12 ft. high and an upper hall 42 ft. high. In the basement are the office of the principal, 18x14 ft., two large class-rooms, 31x22 ft. and 32x15 ft., and a drawing-room 28x18 ft. There are also a lecture-room, 49x30 ft., and a reading-room with a library the same size, all for school purposes. The reading-room is open every evening for the use of the employees. A separate building, 34x16 ft., contains the laboratory and lecture-room for chemistry and mineralogy. The school-rooms are open all day and until 9 o'clock in the evening. They are all lighted by gas and heated by steam. Collections of apparatus and minerals for purpose of instruction have been commenced, and it is the aim to illustrate the lectures as far as possible by facts from every-day practice. The instruction is given by the principal, assisted by Mr. D. D. Davidson, a graduate of Lafayette College, who teaches the English branches, bookkeeping and elementary mathematics.

It is in the highest degree gratifying to record the praiseworthy conduct and punctual attendance of the boys; and the progress in their studies has been very fair, considering their previous ignorance. The nationalities represented in the school are as follows:

industrial sections of Europe, and I do not see why it cannot be introduced with us.

The keynote of success, let me say in conclusion, is not to endeavor to turn out young engineers, but to raise up intelligent foremen.

### Two "Natives."

We give on this page engravings of two curious reptiles, one of which is peculiar to Arizona, and the other, both to Arizona and California. The "Gila monster," or Aztec lizard (*Heloderma suspectum*), is a very curious looking specimen. The engraving was made from a photograph of one brought from Arizona by J. C. Lemmon. The specimen is a female, and is 19 inches long—the body—with its thick kangaroo-like tail, weighing two pounds. Its color is yellow, with clearly defined black scales one-eighth of an inch in diameter, resembling the marking of a butterfly. This peculiar appearance is said to be the model which the Aztecs followed in making their pottery. The Mexicans have also decorations after the same pattern, and the Indians of this coast certainly follow it in their basket work. The reptile is not common, and is known to be the rear guard of the past race of prodigious fauna represented by *Megatherium*, etc. It is slow motioned. The Indians eat it, and the coyote and fox eagerly dig it out of its burrow in the sand, and the white eagle, hawk and vulture prey upon it when exposed. It feeds on the young and eggs of other animals. Here is a curious fact about this reptile, which is that its two sides do not correspond in markings.

We also give an engraving of a "native Californian," a sort of foster brother to our Aztec friend, and occurring in Arizona as well as he. In the volume on zoology in Lient. Wheeler's "Surveys West of the 100th Meridian," it is stated that they found the *Phrynosoma*, or "horned toad," very numerous. There are 11 distinct species of this interesting little reptile, according to Prof. Cope. The one shown in the engraving is the form found in California, and Arizona—*Phrynosoma cornuta*.

In its general aspect it somewhat resembles a frog, and is called a horned toad, though really a nearer kindred to the lizard tribe. In fact, it is a true lizard, and is in no respect a batrachian. The genus, which is North American, is characterized by a more or less oval body, flattened and covered with tuberculated scales, the head having sharp spines or knobs.

In confinement the reptile is sluggish, but it is said to be active in pursuit of insect prey in a wild state. It passes the winter in a state of lethargy in holes dug by gophers and other rodents, coming out in April generally. Those specimens which we have burrow under the soft earth in their box, covering themselves entirely up. They are very abundant on the Fresno plains. Those interested in the natural history of the reptile can find detailed descriptions in Stanbury's "Expedition to Great Salt Lake," and Vol. II. of the "Mexican Boundary Survey."

### Sweepstake Thoroughbrace Wagon.

People who live in mountainous, rough, or newly settled countries, appreciate the uses and beauties of thoroughbrace wagons more than those who live where smooth, well-finished roads are the rule. A great many styles of thoroughbrace wagons are made, and on this page we give an engraving of one made by the Sweepstake Plow company. In the prominent advertisement of the company, which appears upon another page of this issue, may be seen other styles of vehicles of the same manufacture. The thoroughbrace wagons are built for general business, passenger, express, and freight wagons. The two hind seats can be easily removed, thus fitting the wagon for a load of fruit or merchandise. They can also have a top for ataging, and a front and hind boot if desired.

The Sweepstake company will move to their new and extensive works at Benicia next month, at which time we expect to have a description of the new buildings and arrangements for manufacturing.

A CANNON WITH A RANGE OF TEN MILES.—There is now being cast at the Reading, Penn., Iron Works, a cannon which experts say will throw a ball 10 miles, if not 12 miles, whereas 5 and 6 miles is considered a good range for the best cannon now in use. The gun is an improved accelerating or multicharge gun—a modification of the Lyman-Haskell pattern. It will be 25 ft. long, and have a bore 6 inches in diameter. Along the bore will be 4 pockets, in each of which a charge of powder will be placed, with the view of accelerating the ball after it leaves the chamber of the gun and during the progress through the bore. The charge of powder will be 130 lbs., and the weight of shot 150 lbs. It is calculated that a shot from the gun will penetrate through 2 ft. of solid wrought iron.

ENGLAND IMPORTING IRON ORE.—It will be surprising to many of our readers to know that 2,600,000 tons of iron ore were imported into Great Britain last year. Of this importation over 2,000 tons came from Bilbao. This ore was of superior grade, suitable for making Bessemer and open-hearth steel. The total production of iron ore in the United Kingdom for the year was \$17,500,000 tons.

### The Magnetic Needle, and Mining Plans.

Recent events in connection with mining operations show most forcibly the great importance of having the working plans of mines almost mathematically correct, yet we have had plain proofs that many, considered in every way most reliable, have just been the reverse. Many of the mining surveys now in use, says the London *Mining Journal*, cannot be relied on within five or ten yards at a distance from the shafts, and the protracting of one line from the preceding ones, and so on in succession, perpetuates every error, and is a system of "judging," as it is termed, that should not be adopted by the mining engineer. In many instances the taking of the magnetic variations have been entirely disregarded, and this has led to many errors appearing on plans. In taking the meridian there was a great deal of difference in the observation taken on one day and that observed on another. To some extent, no doubt, the atmosphere affected the needle, for oxygen being a component part of it was a substance that attracted the needle, and it was also probable that the heat of the sun also affected it. The difference in the weather and the seasons of the year, it may be taken, had a tendency to a variation of this needle from the true meridian. To determine the deviation of the plane of the meridian, or of the due north, it was usual for the direction of the pole star to be taken while the first star in the tail of the constellation of the Great Bear was passing precisely underneath the polar star. The true pole was a point in the line joining the two stars a little removed from the pole star, just opposite to the next star which is visible to the naked eye. It has been said that greater accuracy has been obtained by taking what is termed the "solar meridian," but how this can be done does not appear to be known to many of our mining managers. One gentleman has informed us that he has taken it frequently by a transit instrument; all that was required being to find the proper time the sun was passing the meridian of a certain place, and then fixing, on some important station on the surface, make the observation at the proper time. The Ordnance maps were generally tolerably correct, and they were used to find the longitude of the place wanted or required. As to taking the time, which, of course, was required to be most exact, it was done by ascertaining the Greenwich time at a place and then correcting it by means of calculation, so as to obtain the mean time at Greenwich.

As to old mining plans, as a rule, it is no doubt correct to say that if they were now brought into use, to have the workings correctly carried on such could not be done without going and comparing them or getting the true meridian again. But it has been stated by one of our mining engineers who has paid a great deal of attention to the subject, that by adopting the solar meridian there would be a universal similarity in all plans, as every plan would be drawn on the proper meridian. Every plan throughout the country would be as parallel as possible, and by that means they would be able to compare them at once. However, the taking of the solar meridian as yet has not been adopted by many of our mining engineers, who consider it of more importance to know the variation of the compass from a certain line. Still it has its advocates, whose number will in all probability increase, for it has its attractions, especially among the young members of the profession.

One of the simpler methods by which the meridian can be approximately determined is by drawing a thin rod vertically on a drawing board or some level surface, the shadow cast by the rod being measured a short time before midday, and the vicinity marked. Through the point with the rod as a center the arc of a circle is struck, when the extremity of the shadow again touches the arc after midday, the point where it touches is marked, and midway between the extremities of the two shadows may be found the point, which is in the same meridian as the rod itself. It is, however, most desirable for future reference to mark by strong stakes at several chains distance on either side of the shaft the meridional line which has been taken as a base for the survey. In the surveying of boundary lines on the surface, or of the mainways in the skeleton of the survey underground, the compass should be entirely discarded. Where very great care has not been taken it may be said the use of the magnetic needle underground, where the greatest accuracy is so necessary, has led to many errors which have led to litigation and loss of time by driving in the wrong direction. Surveying, however, can be done without a needle, especially where there is only one shaft, and this can be effected by two thin copper wires carrying heavy weights at the bottom immersed in buckets of water to diminish the oscillation, a deal straight edge being fixed so as almost to touch each wire at right angles to the line between them. The extremes of six or ten successive oscillations should be marked with a pencil on each straight edge, and the mean taken with a pair of compasses, and the wires fixed to such mean points. Standing behind the wires the surveyor should next send a candle along the heading as far as it could be seen, and fixed in a line with the wires, and this operation should be repeated in the opposite direction, placing a candle against one of the wires, and to check the whole it should be seen whether the

three candles are exactly in line. The latter, being the basis of the whole underground survey, should be permanently marked by a few pegs driven into the roof with nails in them, or by some other marks. On the surface permanent pegs should be placed at some chains distance on each side of the shaft in a line with the wires. By this means there is obtained a line on the surface exactly corresponding with the base line of the operations underground.

This system has been found to be a really good one after the most severe tests that it was possible to have, not only in ordinary mining

plans, and these have at many places been entirely ignored, and with serious consequences to the owners of mines. In one case we are told of two beds of coal which were worked simultaneously according to the plans, and the result was that there was a difference of several chains, which greatly astonished the engineers. Only recently, too, in an action tried in one of the Superior Courts, heavy damages were awarded to a mine-owner for trespass and getting minerals by the party who had gone beyond his boundary, owing to the inaccuracy of the plans. To have plans accurate and

LONE PEAKS, BETWEEN EHRENBURG AND PRESCOTT, ARIZONA

but in tunnelling as well. Surveys for the purpose of ascertaining the extent and direction of underground workings should be so trustworthy and accurate as to enable the surveyor to show from this map or plan the very points on the surface below which the mineral has been taken in every way reliable it has been suggested that there should be a long line on the top, showing the variation of the compass at every time, so that means no errors could well arise. However, the importance of accurate plans in connection with every description of mining opera-

REGION OF THE THOUSAND WELLS, ECHO CLIFF, ARIZONA

away, and to what extent the subterranean excavations have extended. This, under ordinary circumstances he can do by taking the horizontal dimensions of the surface area from which the mineral has been excavated beneath. Another means frequently used in surveying was by having three stones in a line, and testing the compass frequently, when a correct survey could be ensured by a competent surveyor, and this could be done in thin seams of minerals where the theodolite could be brought into use. The magnetic needle, however, was a rather favorite mode of surveying, but in connection with it; but it was affected by magnetic stones and ironstone. Still, in making surveys of mines there can be no question as to the importance of the taking accurate note of the magnetic variations, so as to ensure the accuracy of

tions cannot be too forcibly expressed, nor can the best known systems be too often brought under the notice of mine managers and mining engineers, on whom so much responsibility rests for the safety of those employed under them, as well as for the security of the property placed in their keeping.

THE temperature in the Suto Tunnel at the drill hole, south lateral header, is 112°; at the Savage, 88°; at the Yellow Jacket connection, 90°; at the Yellow Jacket shaft, 76°, and at the Julia, 109°.

EVERYBODY will be glad to know that the managers of the last walking-match held in New York were \$4,000 out of pocket when the show ended.

### The Hydraulic Mining Injunction.

We gave, last week, the details of the suit which has resulted in an injunction being served on certain hydraulic mines in this State, causing them to shut down. This question of the outcome of the whole trouble is an important one, and we have seen no better description of the present situation than is given in the following paragraph from the Grass Valley *Union* of this week, a paper published near the scene of the mining operations which the injunction stops:

Although the injunction suit of the city of Marysville has caused the stoppage of nearly all of the principal hydraulic mines of this county that discharge their tailings into the Yubas and their tributaries, all of them have not been enjoined, or were not as late as Saturday; but the mines that were then operating were hourly looking for the service of the legal process which would cause their stoppage. Of those that have stopped theirs has been quite a general dismissal of employees, and the uncertainty of this situation causes much anxiety to the miners who have families depending upon them for support. While the suspension of work is a great inconvenience and loss to the mining and canal companies, that of itself is not as great a hardship as that which befalls the working miner. The companies have to endure the loss of the interest upon their investment for the time being, from which they can recoup when permitted to start up their works again, and the gold in their claims does not escape in the meanwhile. But with the miner his labor is his capital, and every day's loss of labor is absolute, for which he can have no compensating return. To him and to every business contingent upon the working of these mines the matter is of grave concern. There is a hope that a way will be found to dissolve the temporary injunction, and permit the work of the mines to go on as was done in the Bear River suit, but if the miners are compelled to remain idle until the final close of litigation in the Supreme Court it will be almost a life and death matter with hundreds of people.

So far, there has been no injunction placed upon the hydraulic mines bordering on the Bear river, but it is understood that proceedings of that kind are under way, and at almost any day the hydraulic companies of that region may expect a summons to stop work. It is the impression that the farmers and the people of that portion of the valley injured by the debris have combined for a general onslaught upon the hydraulic miners, and that it is the intention to shut down every mine of this character in the State. The anti-debris men and the newspapers that speak their sentiments say that the war has begun in earnest and that there is to be no peace until hydraulic mining is discontinued entirely. It is said that the anti-debris associations have and are collecting a large fund, the money being raised by a tax per acre on farming lands, amounting to much more than the tax levy by the debris law for reclamation purposes. These valley people are showing themselves terribly in earnest, and the miners may make up their minds that they have a big fight on their hands, which must be fought through to the bitter end. Whether the contest will be alone confined to litigation in the courts or to adverse legislation in the Capitol of the State, time alone will tell.

### The Lone Peaks, Arizona.

We illustrate one of the peculiar isolated peaks which arise in different portions of Arizona. One of the most bold and pleasing of these is to be seen on the old Stewart & Pearson stage road from Ehrenberg to Prescott. After riding for miles and hours over the broad sandy plains, with the distant mountains forming a pleasing enclosure to a vast natural stage upon which many a weird and midnight scene has been enacted, to come holdly upon these lone peaks (there are two of them) standing side by side is a scene worth the whole ride. As the stage passes by close to their base, they look down frowningly upon you; and were you superstitious, would almost think they spoke to you in the eerie stillness of the night.

### Region of the Thousand Wells.

"The Region of the Thousand Wells," of which we give an illustration on this page, are located on the western slope of the Echo cliff on the Colorado river, Arizona. It is a wild region, the surface is deeply furrowed or eroded, and shows the work of great grinding and wearing agencies in the years ago. This piece of landscape includes a few of many remarkable natural formations known as the "thousand wells." After a shower these pot holes are filled with water. These wells are used by the Indians as water sources during their wanderings; but the chosen abode of the Indians is on the eastern slope of Echo cliffs, where numerous springs are found which are their famous watering places.

THE losses to Iowa farmers this year from poor seed will amount to \$2,000,000.

BRUSH DYNAMO-ELECTRIC MACHINE.

## Excelsior Blasting Powder,

—MANUFACTURED BY—

## THE EXCELSIOR POWDER COMPANY.

This is no NEW PATENT NON-EXPLOSIVE SAFETY POWDER, but the GENUINE STANDARD ARTICLE, and as safe to use and handle as any Nitro-Glycerine Powder manufactured. The Fumes and Gases, common in other Nitro-Glycerine Powders, are almost destroyed, and do not leave the miner with headache or nausea. Among the numerous recent testimonials the following is but a fair sample, constantly received, attesting the superiority of EXCELSIOR POWDER:

AUBURN, Cal., May 26, 1881.—EXCELSIOR POWDER CO.: I send you, per Wells, Fargo & Co., a box containing samples of country rock through which I am running our tunnel on the Conard Mine, and through which we have now run 425 feet, 275 feet of it having been done with EXCELSIOR POWDER. If any one can produce harder rock I would like to see it. I here say that I can do more execution with your No. 2 Powder in this rock than I can with any No. 1 Powder of any manufacture I have ever used, and I have used every kind now manufactured here, excepting "Tonite," and I have had 20 years' experience in blasting. Respectfully yours, E. W. ROBERTS, Superintendent.

Give this Powder a trial and you will use no other. For Strength and freedom from noxious fumes, it has no equal. Address all orders to EXCELSIOR POWDER CO., No. 330 Pine Street, Rooms 53 and 54, Academy Building, San Francisco, Cal.

## STEEL CASTINGS

### FROM 1-4 TO 10,000 lbs. WEIGHT.

True to pattern, sound and solid, of unequalled strength, toughness and durability. An invaluable substitute for forgings or cast-iron requiring three-fold strength. Casting of all kinds, Shafts, Dies, Hammerheads, Crossheads for Locomotives, etc. 15,000 Crank Shafts and 10,000 Gear Wheels of this Steel now running prove its superiority over other Steel Castings. CRANK SHAFTS, SHOES, DIES AND GEARING specialties. Circulars and Price Lists free. Address

**CHESTER STEEL CASTING CO.,**  
Works, CHESTER, Pa. 407 Library St., PHILADELPHIA

### Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

### Sewing Machines.

**EXCELSIOR  
BLASTING POWDER**

MANUFACTURED BY THE

Excelsior Powder Company.

This is no so-called "safety" Powder, but a powerful explosive, and as safe to handle and use as any nitro-glycerine Powder on the continent. There is no headache or nausea in the use of this Powder, as the noxious fumes are entirely done away with. It is put up in cartridges of any size to suit consumers and is exploded with cap and fuse, the same as any other high explosive. The following testimonial is a sample of hundreds of the same tenor being constantly received:

GOLD HILL, August 17, 1880.

AGENT EXCELSIOR POWDER CO.—Dear Sir:—I have used your Powder in test cement and hard blasting rock, and find it superior to any Powder I use on the Comstock. It does its work effectually, and does not leave the person using it with a severe headache, like the other Powders do to the majority of miners. In recommending it I would suggest, give it a fair trial and I am confident it will speak for itself. Wishing your Company success,  
I am respectfully yours, etc.,

GEORGE CLARK,

Foreman Sierra G. and S. M. Co

**Scientific and Practical Books  
on Mining, Metallurgy, Etc.**

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,

Mining Engineer and Metallurgist.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurates, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple or der. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, \$7.50

## PATENTS AND INVENTIONS.

### List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," U. S. and Foreign Patent Agents.

FOR THE WEEK ENDING MAY 31, 1881.

242,320.—SIDE-HILL PLOW—Frank A. Hill, San Leandro, Cal.  
242,233.—WAVE-POWER—J. W. Swales, S. F.  
242,236.—SEWER TRAP—Pedro Torelli, Benicia, Cal.

FOR THE WEEK ENDING JUNE 7, 1881.

242,550.—BALING PRESS—Nelson Arve, Utah.  
242,567.—OATE—A. P. Campton, Rhonerville, Cal.  
242,610.—APPARATUS FOR SEPARATING SULPHURETS IN OIL—Washington—W. E. Devan, Owin Mine, Cal.  
242,639.—GRAIN THRESHER—J. S. Heald, Vallejo, Cal.  
243,040.—GRAPE CRUSHER AND STEMMER—J. L. Heald, Vallejo, Cal.  
242,045.—CASTER—Geo. W. Horne, S. F.  
242,542.—DRESS CHART—Ellen K. Kinker, Corvallis, Oregon.

243,069.—COMPOUND FOR FACILITATING THE AMALGAMATION OF GOLD AND SILVER—W. H. D. Mathews, C. C. Ayres and M. D. Campbell, Bodie, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

### Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign, Patent Agency, the following are worthy of special mention:

**GRAPE ELEVATOR CRUSHER AND STEMERS.**—John L. Heald, Vallejo. Dated June 7th, 1881. No. 242,640. This apparatus is principally useful in preparing grapes for wine making. It consists of a pair of corrugated or fluted crushing rollers, which run together and are driven by suitable gearing; these rollers being provided with an attachment, by which they are separated and thrown out of gear whenever any hard substance or body which could injure them passes through. Below these rollers is a cylindrical case having its lower part perforated, and having a shaft extending longitudinally through it. This shaft has radial arms attached to it, so as to form a spiral extending from end to end, the object of which is to press the grape pomace through the perforated bottom of the cylinder, and to carry the stems and worthless portion out at the end of the cylinder. Below this cylinder is an inclined grating, upon which the pomace falls, and from the lower end of which it is delivered into the cars, to be carried to the press, a hinged, movable gate controlling its discharge. The grapes, either loose or in boxes, are placed upon a peculiarly constructed elevator, the whole forming a very effective apparatus for the purpose.

**SEWER TRAP.**—Pedro Torelli, Benicia. Dated May 31, 1881. No. 242,236. This invention relates to inlet or slit hasins and traps for sewers, to be placed at the corners of streets and connecting with the sewer pipes. It consists in a double compartment chamber, said compartments opening into each other at the bottom; one of which is so constructed as to contain earth, or other like substance, to prevent the escape of the gas through said compartments, while allowing ready access thereto for purposes of cleaning, the other of said compartments receiving the water and preventing the return and escape of noxious vapors by reason of the separating partition reacting below the water level. Both compartments are covered by a lid above, and provided with an opening, fitted with a plug, in the bottom, to allow the escape of the water when desired, which remains below the level of the exit part. These compartments are appropriately provided with inlet and exit parts, the former being in relation with the gutter, and the latter connected with the sewer pipe. The advantage of the invention is the ease with which it can be reached in all its parts to clean it.

**GRAIN THRESHER AND SEPARATORS.**—John L. Heald, Vallejo. Dated June 7th. No. 242,639. This invention relates to certain improvements in that class of machines in which the threshing and separation of grain are performed as a continuous operation; and it consists in such a combination of beaters, pickers, carrying belts, sieves, chutes and fans, that the inventor is enabled by their use to produce a very perfect separation of the grain from the masses of straw with which it leaves the threshing cylinder, and to thoroughly clean the grain from chaff, harley, mustard or other foreign substance or impurities, so that it is delivered as first class grain by the single continuous operation, and without the use of any supplemental machine or fanning mill, such as are usually hauled around with the separator, the object being to combine the whole in one machine.

### Sewing Machines.

Several first-class styles, good as new, will be sold at a bargain. Call on, or address H. F. D., at this office.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

### Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. F. OSBORN—San Francisco.  
A. C. KNOX—Napa and Lake counties.  
G. W. McCRAW—Santa Clara county.  
M. P. OWEN—Santa Cruz county.  
J. W. A. WAGNER—Merced, Tulare and Kern counties.  
JAMES C. HOAG—California.  
B. W. CROWELL—Yuba and Sutter counties.  
D. W. KELLER—Solano and Sacramento counties.  
GEO. W. FAHRION—Plumas county.  
GEO. H. HOPKINS—Amador county.  
A. LEONARD MEYER—Utah and Idaho Ter.

### Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct or if the paper should ever come beyond the time desired, be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time we cannot be responsible for the errors or omission of agents.

PERSONS receiving a sample copy of the PACIFIC COAST PRESS with this notice marked, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We will send it, on trial, at the rate of \$3 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

How to STOP THIS PAPER.—It is not a herculean task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired, you can depend upon it we do not know that the subscriber wants it stopped. Stop be sure and send us notice by letter.

ANDERSON SPRINGS, in Lake county, 19 miles from Calistoga (over a grand, picturesque route, via Mt. St. Helena) are among the best in this State. They are situated in the midst of a natural park, full of beauty and interest to the naturalist. Good home-like accommodations at reasonable rates are invariably furnished by the Anderson family.

### LEACHING GOLD AND SILVER ORES.

CHLORINATION OF  
GOLD SULPHURETS A SPECIALTY.

Room 49, Merchants' Ex.,  
SAN FRANCISCO.

# THE O'HARRA CHLORIDIZING FURNACE.

Patented, 1878.

This Furnace is Constructed with two SEPARATE HEARTHES, one for DESULPHURIZING and one for CHLORIDIZING the Ore.

BOTH PROCESSES ARE PERFORMED AT ONE OPERATION.

An endless chain carrying conveyors or scrapers passes continuously through over both hearths, going one way through one chamber and the other through the other chamber. By this means the ore is fed and discharged at the same end of the furnace.

The chain and hoes pass out of the furnace into the open air,

SIDE ELEVATION OF THE O'HARRA FURNACE.

in the revolution, so they are not too much heated.

A cheap furnace to build and to run.

Supplemental fireplaces are so arranged that the heat is under perfect control.

PLAN OF THE O'HARRA FURNACE.

The process is essentially the same as the well-known Freiberg process; but the mechanical devices applied to the furnace and the peculiarity of its construction enable the inventor to thoroughly desulphurize and chloridize the ore to a higher percentage, than other furnaces, and with less cost for fuel and labor.

END VIEW OF THE O'HARRA CHLORIDIZING FURNACE.

Cost of 1 Ton.....	1 10

THE COST OF ROASTING AT EXCHEQUER MILL, 20 TONS OF ORE IN 24 HOURS, IS AS FOLLOWS:

One Man.....	\$ 4 00
One Man.....	3 00
Wood—1 1/2 cords, at \$3 per cord.....	5 25
Salt—1,600 lbs., at 2 1/2 cents.....	40 00

Cost of 20 Tons.....	\$52 25
Cost of 1 Ton.....	2 61 1/2

Potter & Hall, of Copper City, who have two O'Harra Furnaces, one for drying and one for chloridizing the ore. They say: Our ore is of a very base nature, consisting of sulphide of copper, iron, antimony and other base metals. Our average battery assay is about \$16 per ton. By the use of the Furnaces we roast and mill from 40 to 45 tons per day, and obtain from 90% to 95% of the assay value.

J. F. Ferguson, assayer, of Copper City, says: Our ore is of a very refractory nature, consisting of sulphides of copper, antimony, iron, and other base sulphides. We work on an average of 40 tons in one day of 24 hours, the ore averaging about \$16 per ton. Our chlorinations run from 90% to 95%. We work the ore up to 95% of the fire assay. The furnace costs very little for repairs. Both furnaces give entire satisfaction. They do the work intended as near as any furnace can do.

Lewis Chalmers, of the Isabella G. & S. M. Co., Silver Mountain, says: The O'Harra Furnace did all that is represented in the MINING AND SCIENTIFIC PRESS, roasting and chloridizing, at the figures there given, antimonial and arsenical sulphurates of silver up to from 84% to 95% of the assay.

The Washoe and Ophir Tailings Co. say: The O'Harra Furnace in operation at our mill for the past year has worked to our complete satisfaction. Our average assay is \$11 per ton. We roast with the furnace from 35 to 40 tons per 24 hours, chloridizing from 85% to 95% of the assay.

## INCERSOLL ECLIPSE ROCK DRILLS.

The Most Economical Air Compressors in the Market.

## MINERS' HORSE-POWER.

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The Power is mainly built of wrought iron. The hoisting drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

## COKE. PATENT. COKE.

This COKE is exclusively used by Prof. Thomas Price, in his assay office, by the Selby Smelting and Lead Co., Prescott, Scott & Co., Risdon Iron and Locomotive Works and others in this city. Large supplies are regularly forwarded to consumers in Salt Lake and Nevada, to the Copper Queen Mining Co., Longfellow Copper Mining Co. and other consumers in Arizona. The undersigned are in receipt of regular supplies from Cardiff, Wales, and offer the COKE for sale in quantities to suit purchasers.

BALFOUR, GUTHRIE & CO.,

316 California St., San Francisco.

## DEWEY & CO'S

Scientific Press

Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

Established in 1850.

### RANKIN, BRAYTON & CO.

Office—127 First Street, San Francisco, Cal.

### Builders of Engines, Boilers, all Classes of Machinery.

PLANTS FOR GOLD AND SILVER MILLS,

Embracing the latest and most Improved Machinery and Processes for Base and Free Ores.

WATER JACKET SMELTING FURNACES.

For both Galena and Copper Ores of the Most Improved Construction.

Having Built nearly every successful working Furnace on the Coast, we are prepared to guarantee the best results attainable in all classes of Ores.

HOISTING AND PUMPING MACHINERY,

Embracing all Known Improvements.

WHEELLOCK'S AUTOMATIC CUT-OFF ENGINE.

Beyond Question the most economical and perfect working Engine now made.

WALKER'S COMPOUND STEAM PUMPS.

The best in use. Will work with thirty per cent. less steam than any other Pump in the market.

Sole Agents for HOWELL'S IMPROVED WHITE FURNACE.

The only successful Chloridizing Furnace made. Over fifty of them in use on this Coast.

Parties Wanting any kind of Mining Machinery are requested to send for Illustrated Circular.

## William Hawkins,

(SUCCESSOR TO HAWKINS & CANTRELL).

### MACHINE WORKS,

210 and 212 Beale Street, bet. Howard and Folsom Sts., - - San Francisco.

Manufacturer of

### IMPROVED PORTABLE HOISTING ENGINES,

FOR MINING AND OTHER PURPOSES.

Also of the HAWKINS' PATENT ELEVATOR HOIST, for Hotels, Warehouses and Public Buildings.

### Steam Engines and all Kinds of Mill and Mining Machinery.

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

### Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when advisable.

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Capstans, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

Walker Bros',  
Wood-Working  
Machinery.

# MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO.,  
Publishers.

SAN FRANCISCO, SATURDAY, JUNE 25, 1881.

VOLUME XLII  
Number 26.

## Foundry Notes.

The foundries of the city are generally pretty busy just at present, and all of them have more or less large work on hand. It is a noticeable fact that orders for mining machinery have lately come to this city from Colorado and Montana. Considerable machinery has been shipped to Montana, in the shape of mills, hoisting works, furnaces, etc. One foundry alone has sent \$30,000 worth of machinery to Montana recently. Smelting furnaces and hoists are also being sent to Idaho. As to Colorado, it has been generally supposed that we are too far off to receive any orders from there, but the excellence and superiority of the mining machinery made at our foundries cause orders to come here. A lot of amalgamating machinery went from here to Colorado this week. At the

## National Iron Works.

They are just completing a locomotive for the Empire coal mine and Railroad Co. to use on their narrow gauge line. It is a six-wheel, connected tank style, the same as built by the Baldwin Locomotive Works, of Philadelphia. This engine will weigh in working order, about 35,000 lbs. It is strongly and substantially made and will be finished handsomely. These works are also building three locomotive motors for the Presidio Railroad Co. Each of these engines will weigh about 16,000 lbs., in working order.

The works are manufacturing a hydraulic oil press for the firm of Haycock, Tallant & Colton, in this city. They have also just shipped three portable mining hoisting engines, of the peculiar popular type made by them. They have shipped to La Gata mining company, at Julian mining district, San Diego county, one of Kendall's one-stamp quartz mills and three of these mills have been shipped to Honduras, for the Honduras or New York and Rosario mining company.

An engine and boiler for a flour mill in Mexico was shipped by the last steamer, as was also the gearing, etc., for a cotton mill at Tepic, Mexico.

## Parke & Lacy.

Though not actually in the foundry business, they have made to their order a large amount of mining machinery in this city. They have just supplied to the Tehuantepec Inter-Ocean Railroad Co., the first of its outfit for the beginning of the work on the line. This consisted of Burleigh air compressor, large Burleigh drills, hoisting engines, etc. These articles were shipped to Salina Cruz. The company is employing natives on its work, but Parke & Lacy sent men down from here to take charge of the machinery.

**QUARTZ MILL IN CALISTOGA.**—A quartz mill is being constructed in Calistoga, calculated to reduce by dry process 20 tons of ore per day. Dodge's pulverizer is to be used, with grinding pans and settlers. Many tons of ore, assaying well, it is said, are waiting on the dump on St. Helena mountain, some four miles distant. If successful gold or silver mines are here developed (in the Coast Range), it will be a new and important fact to the world at large. We expect to further mention this mill when in operation.

**AT THE SUTRO TUNNEL.**—On the 11th inst., the water from the Combination shaft was turned into the new line of large boxes, and on the 12th inst. the drain boxes carrying the water from the north and south lateral boxes were connected with the large boxes. The drain boxes are now receiving from the Comstock mines over 4,500,000 gallons of water per 24 hours, and have a capacity to carry over double that quantity. The water has a temperature of 118°.

The Homestake mining company has declared a dividend of 30c per share, payable at New York on the 25th. From a 30-stamp mill in 1877, the company is now running 440 stamps. It now owns or controls the claims known as the Homestake, Father de Smet, Golden Terra, Giant, Old Abe, Deadwood and Highland,

## New Sinking Pump.

We illustrate on this page a new form of sinking pump for mining purposes, made under

mining pump, but arranged so as to be lowered down a shaft or winze by means of a wire rope, where it hangs while at work, as it does not need to be secured to timber or otherwise fastened in place. The benefit of such a pump will

tion where the men cannot work within 400 ft. of it. The pump is in a very hot place indeed. It has a 12x18 steam cylinder, and a 7x18 plunger, with a capacity of about 20,000 gals. per hour.

The weight of the pump is about 3,400 lbs., and its own weight will keep it in place all right. It is hooked on and lowered right down. The air or steam pipes, and the water pipes are made in equal lengths, so that they are simultaneously lengthened as the pump is gradually lowered. There is nothing movable on the outside of the pump, so there is no danger of its being broken. It may be run by compressed air or steam. Either rubber hose or iron pipe may be used for connection. The Cope & Maxwell pump is too well known, in the mining regions, as to details of construction and operation, to require any extended description from us.

## Safety Attachment for Mine Cages.

Douglas Brown, of Prescott, Arizona, has just patented, through the MINING AND SCIENTIFIC PRESS Patent Agency, a new form of safety attachment for safety cages. It consists in the employment of inclined arms having their outer ends formed to engage and hold on the guide timbers between which the cage moves, while their inner ends are connected with a ring secured to a vertically-sliding spindle or king-bolt having springs to draw it down forcibly if the rope breaks, and thus cause the ends of the inclined arms to engage the guide timbers. As soon as these arms become engaged and fixed in the guides, the whole weight of the cage is transferred to the king-bolt by which it is suspended, and through it a direct power is exerted to fix the arms in the guides independent of the spring.

A sliding ring or sleeve upon the king-bolt below the attachment of the inclined arm, is connected with them by stay, or bracing arms which cause both the arms to be thrown out simultaneously, and equally prevents them from being thrown out too far by the shock, and assists in strengthening and bracing them. The frame of the cage has clips which extend upon each side of the guide timbers, where the safety arms will engage them, and thus prevent the timbers from being split by the arms when they are forced into the timbers. Rubber buffers or springs below the nut at the top of the king-bolt relieve the jar when it springs up on the catches, and the platform or floor may be also supported upon springs to relieve the force of the blow.

SUIT has been commenced in the Superior Court by N. Gregovich against the Tilden M. Co., A. J. Ralston, F. Locan and W. M. Buoker, to set aside an election of defendants as Directors of the company. The complaint alleges that no by-laws were ever passed or adopted by the corporation, or the stockholders thereof; that on the 7th of June, 1881, persons who claimed to be stockholders of the company held an election for Directors. At that election defendant Ralston voted 33,208 shares of the company's stock for himself, Locan and Buoker; that 49,950 votes cast by Ralston were based upon 49,950 shares of the capital stock, and were accumulated and were distributed for the defendants, Ralston, Locan and Buoker, in accordance with section 307 of the Civil Code; that said Ralston had no right to vote more than 200 shares; that plaintiff held and was the owner of the 49,950 shares of stock voted by Ralston.

The Copper Queen mining company, of Arizona, incorporated in New York, April 2, 1881, has declared a monthly dividend amounting to \$25,000, or 10 cents per share, payable July 1st. This is the first dividend.

A DISPATCH from Tombstone records the development of a large ore body in the Tombstone mine. Some of the ore runs as high as \$12,000 per ton, and it is estimated that the ore in sight is worth \$1,250,000.

It is rumored that the Jennie A mine, White Pine, has been sold to English capitalists for \$250,000.

NEW SINKING PUMP FOR MINING PURPOSES.

the Cope and Maxwell patent, but from a design by Parke & Lacy, agents in this city, who devised its peculiar arrangements to meet a demand on this coast. It is a vertical plunger

he recognized when it is stated that the pump from which the photograph from which the engraving was made, is now at work on the Yellow Jacket mine, on the Comstock, in a posi-

## CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—E.S.

### Wood River Mines.

(From our Traveling correspondent.)

Some of the rich Mines and Fine Prospects.

To the north of Croy's gulch and about six miles west of the town of Hailey, is the finest group of mines yet discovered in this famous district. The formation here is lime, with granite on the north, and quartzite on the south, and a quartzite lead of from 20 to 100 ft. in width, running through the middle of the lime belt. The general course of this belt is northwest to southeast. The galena ledges have been found on one side or the other of the quartzite lead and sometimes under it, in which latter case the croppings are of a peculiar dark color, supposed by experienced miners to have been caused by fumes arising from the lead underneath.

Some of the ledges do not crop out on the surface, making

#### Prospecting a Difficult and Tedious Task.

Where croppings are found they are composed of oxide of iron, lead and quartzite. The ore is sulphide of lead (galena) with here and there some carbonates. The leads vary in width from a few inches to 15 ft., although the average width of the pay ore cannot be put at from more than 18 inches to two ft., in those mines which make the best showing. Mr. D. C. Coleman, who is a pioneer prospector in this district, says that he has not seen any galena ores that assayed less than 85 ozs. in silver, and a great many samples that went as high as 2,000 ozs. The average amount of lead contained in this ore is 65%. Considerable iron runs with the galena as gangue and is said to make excellent flux for smelting.

The mines in the immediate vicinity of this town of Bullion are too numerous to mention. The belt throughout this entire limestone belt are

#### Staked Out for Miles

With poets and monuments, so that they now resemble Lone Mountain Cemetery. Wherever iron croppings penetrate the surface is found a stake and notice, but in a majority of cases nothing else has been done. The Mayflower and Bullion did not measure more than two or two and one-half inches in width where the discovery was made, but the former has already attained a width of seven ft. between the walls, at a depth of 75 ft. below the surface. In the Bullion, at a depth of 160 ft., are found two or three different pay chutes, varying from three to 20 inches each, with iron and ledge matter intervening. The ore at this depth will assay as high as 3,000 to 4,000 ozs., being mostly pure chloride of silver, but for reasons best known to the owners very little of this kind of ore finds its way to the surface.

There is a tunnel 180 ft. in length, and a shaft 160 ft. in depth, with a number of drifts and stopes in ore that seems to improve from day to day. Both the Bullion and the Mayflower belong to Salt Lake parties, and are under the superintendence of Col. E. A. Wall. About 70 men are now at work, principally in constructing roads to enable machinery for bolting works to be taken to the mines.

The Jay Gould, situated due north of the Mayflower, was sold a few days ago to Warren Hussey, and associates, for \$60,000. This mine has also produced some very high-grade ores, but was very badly handled by parties who worked it under a lease.

About one mile east is the

#### Idahoan Lode.

In a contact of lime and quartzite, with the usual iron croppings on the surface. Last year it shipped 142 tons to Salt Lake, which realized \$128 per ton after deducting all expenses for mining, sacking, freight and smelting. The vein varies from five ft. in the open cut near the mouth of the tunnel, to 15 in. in the narrowest places. There is a fine ledge of pure galena, and another one of carbonates, that runs from 47 to 160 ozs. in silver. About 200 tons of ore have been extracted this year, some of which still awaits shipment.

There is a tunnel, 200 ft. in length, running in solid ore; and 40 ft. east of the tunnel is an open cut, 22x45 ft., from which a 50-ft. shaft has been sunk on the ledge. Ten men are now engaged in taking out ore or cutting timbers.

One-half mile from Bullion, in a northwest direction, are two excellent prospects, known as the Bay State and Silver Pass, belonging to D. C. Coleman. The Silver Pass is 12 in. wide on the surface, and can be traced for 200 ft., in a contact of lime and quartzite. Two men are now at work running a tunnel to tap this ledge, which they expect to do at a depth of 50 ft. The Bay State has been stripped for 30 ft., exposing the same kind of vein. Experienced miners say that these surface indications are far better than those of the Bullion or Mayflower, but unfortunately it will require more capital than the owner is possessed of to open up the ledges in proper shape. One mile farther on in the same direction are what is known in this vicinity as the Frenchman's mines, the Chicago and its extension, which have just been bonded for \$1,200.

#### The Altitude

Of nearly all the mines about Bullion is over

7,000 ft., and the hills are very steep, making it anything but easy to get around except on the back of a mountain goat.

About three-quarters of a mile west of Wood River, and two miles below Hailey is the Star, discovered by Zach. Hayes, in the fall of 1879, and sold to A. Wolters, E. S. Chass and David Falk, of Boise City. It is a contact vein, lying between syenite, or hornblende granite on one side and lime on the other, with a pay streak varying from a few inches to three ft. in width. The ore is argentiferous galena, of very high grade, and in the west shaft, rich carbonate ore is found that assays 740 ounces. A sample of five tons of the former was sent to Salt Lake, where it showed 184½ ounces silver, and 60% lead. The ledge can be plainly traced a distance of 800 ft., and in some places solid galena may be found on the surface. The developments on this mine consist of a 280 ft. tunnel, and a winze started 156 ft. from the mouth of the tunnel and raised to the surface. One shaft has been started 440 ft., and another 730 ft. above the tunnel. The first is now down 67 ft. and the other 50 ft., all showing splendid bodies of ore. As no crosscutting has yet been done, the width of the ledge is still unknown.

Messrs. Wolters, Falk and Lieut. F. J. Pat-ten, U. S. A., have also

#### Erected a Smelter

On the east side of Wood River, about one and one-half miles above Hailey. It has a Fraser & Chalmers' four tuyeres furnace, with a capacity of 15 tons of heavy galena, or 25 tons of carbonate ores. The blast is furnished by a Root blower, and the machinery is run by a Loeffel's turbine wheel, having a 24-ft. head of water. The flux used is pure calspar and hematite, or red oxide of iron, which is obtained at a distance of 18 miles. The charcoal costs them from 20 to 22 cents per bush., delivered. This is the pioneer smelter on Wood River, and will be started up in the course of a few days.

I have just been shown, by Mr. Emil F. Gaetz, specimens of some kind of asphaltic or

#### Bituminous Mineral

Strongly resembling coal, which he has found in a large bed two miles south of Silver creek. The bed is 60 ft. wide and can be traced for three miles, with fire clay, 6 to 8 ft. in thickness, on the north, and porphyritic slate formation on the south side. The mineral, whatever it is, looks very much like bituminous coal; colors brown and crumbles up when heated and appears to contain bitumen. Should it prove to be coal it is a very important discovery, but its close proximity to the lava formation seems to dispel all hopes in that direction.

A. L. M.

### Volatilization of Gold.

EDITORS PRESS:—Your urbane correspondent, Mr. Herbert Lang, who, in his first paragraph, pays me the compliment of calling me a "distinguished author," and in his second implies a doubt of my veracity, or my sanity, questions the sufficiency of the evidence on which I have affirmed the volatilization of gold in the roasting of certain ores with salt. (Vide pages 121-4 Leaching Gold and Silver Ores).

It strikes me that Mr. Lang has read your extract from my book somewhat hastily, as he confounds the "yellow sublimate" with the "fluffy sublimate." Certainly, I should think he has not read the book.

I regret to say that no sample of either of those substances was preserved, and I was too busy at the time to make any further examination of them than sufficed to prove their richness as stated.

Had Mr. Herbert Lang read my book he would not need to ask how I knew that "the material could be roasted with little or no loss if no salt was used, because some assays had been made in that way." He would have read, in the article on "Assaying Concentrations," that I disapprove, in general, the practice of roasting the assay, and give several methods of assaying sulphurets without roasting; consequently he would have inferred my meaning, which was that nearly as high results were got from assays which were roasted (without salt) as from those which were not roasted. Of course there might be a loss in assaying by any method, but as that has not been proved it cannot be considered. The roasting of two one-half-ounce samples alone would certainly be a slender basis on which to establish a hypothesis, but, taken in connection with the other evidence, it, to my mind, clearly established a fact. Mr. Lang says, "it is a curious fact" that no one has previously discovered the demoralizing effect of salt in gold assaying." In reply I would ask, who ever uses salt in gold assaying, except as a covering for the assay, in which case its action is totally different from that produced when the ore is roasted with salt before being assayed? I attribute the loss of gold in roasting with salt, when the salt is added early, not to the direct action of the salt, but to that of volatile metal chlorides produced in the roasting.

I am further inclined to attribute the effect to the copper chlorides more particularly, because I have observed that concentrations which did not contain more than a trace of copper did not suffer a loss in roasting, with even 10% of salt charged with the ore. I have not, however, established the fact that copper was the cause.

The "peculiarity" referred to by me con-

sisted simply in the fact that the ore sustained such a large loss, in which it appears to have been peculiar. Since writing the book I have seen an analysis of a sample of the ore, which showed "traces" of selenium and tellurium.

The "expert metallurgist" alluded to is well known to be such, and it would give me pleasure to mention his name in this connection, but that I fear it might not be agreeable to him, as "reduced circumstances" had induced him, much to his credit, I thought, to seek employment with me as a common furnace hand, rather than as a hurden on his friends. He left me before I discovered the cause of my difficulty, and is now, I am happy to say, in a position more worthy of his talent. I hear he is as incredulous as Mr. Lang himself on the subject of the loss of gold.

The sulphurets referred to were those of the Murchie mine in Nevada county. They had been tried by several well-known operators, in Nevada and San Francisco, whose failure to work them successfully was the reason that a contract was given to Aaron and Irelan.

After the expiration of our contract, I visited Nevada, and Mr. Crosby remarked to me that those sulphurets lost gold by being roasted with salt. I did not inform him as to how I had succeeded in preventing the loss, but he made the discovery for himself, and, having the freight and other advantages in his favor, has since worked them in a similar manner, and with as good results as I did. I have no doubt that Mr. Crosby as well as G. P. Dutkin, M. E., will endorse my statements as to this ore.

If my memory is not at fault, Kustel says, in one of his earlier works, on the authority of Plattun, that there is no sensible loss of gold in roasting sulphurets, unless the operation is unduly hurried, adding that the addition of salt makes no difference. In his later edition of "Roasting of Gold and Silver Ores," he repeats this statement in one place, but, in another, states, possibly in reference to the Murchie ore, that some operators have complained of a heavy loss of gold in roasting certain ores with salt. [If I am in error Mr. Kustel will please correct me.]

The evidence upon which I have affirmed the volatilization of gold in this case is as follows:

Some ten carloads of sulphurets were roasted with from 1% to 2% of salt, charged with the ore. The assays of tailings indicated a yield of 90% or over, but the gold collected fell considerably short of 85%. This discrepancy was proved not to be due to losses in the leaching department.

The roasted ore assayed lower than the raw, whereas the reverse ought to have been the case. The enblimates deposited on the outside of the furnace under a low draft, and that in the fine, were rich in gold.

After the manners of applying the salt was changed, as described in my book, the assays of tailings as compared with those of the original ore corresponded with the amount of gold collected.

The roasted ore assayed higher than the raw sample, by an amount corresponding to the loss of weight. A half-ounce of the ore, roasted with 4% of salt, yielded, when smelted, about 50% less than another half-ounce roasted without salt. Mr. Crosby found that the ore lost gold when roasted with salt in the usual manner, and several experienced operators failed in working it to a good result.

Under the first system of roasting we lost money on our contract, and the missing gold was not in the tailings; under the second we realized a good profit with richer tailings.

It would certainly be interesting to know in what form the gold was carried over. My book being merely a practical handbook, I used the term volatilize in its literal sense, as flying away, which certainly the gold did, whether in the form of a gaseous compound, or as metal in minute particles.

In conclusion, I will say I still have some samples of the "very remarkable substance" in question, which I shall be happy to place at the disposal of any gentleman who may desire to experiment upon it, on condition of his publishing the results in your paper. C. H. AARON.

### Experiments in Chlorination.

EDITORS PRESS:—Recently a trial lot of concentrations from the Atlas mine, Tuttle town, Tuolumne county, was subjected to roasting and chlorination at the Golden Gate mill, near Sonora. The ore from which these concentrations were derived consists wholly or partly of cubic pyrites, contained in a matrix of dolomite, the carbonate of lime and magnesia, as shown by my analysis. The result of roasting in the reverberatory furnace, at a light red heat, of such ore, is easily foreseen. While the pyrites are satisfactorily desulphurized, as invariably occurs under the intelligent supervision of the managers of the above works, some of the carbonic acid, united with the alkaline earths, is also driven off, and caustic lime or magnesia, or both, are the result. As might be expected, in dampening, the alkaline earths are converted into hydrates with an increase of bulk. The consequence of the "slaking" is that the mass solidifies in the vat, and becomes not only impervious to the chlorine gas, but nearly so to the tools used in removing the mass. On the other hand, the chemical reactions between the hydrates and chlorine are such as to preclude the formation of gold chloride until the more powerful affinities of the lime and magnesia are neutralized.

The process is certainly an effective one if bleaching powders be desired, but as far as the profitable extraction of gold is concerned, the valuable metal might as well not be present. No doubt this result, which should have been foreseen, will put a quietus to the rumor of the intended erection of chlorination works at the Atlas mine.

HERBERT LANG.

### Reduction Facilities.

Not long since an article appeared in these columns, setting forth the advantages obtained by prospectors, and owners of small mining properties brought about by the Carson and Colorado railroad. The Lyon county Times of recent date has an item descriptive of the mill at that place and its crushing facilities. It further says it is just now an object of interest to our people. It is employing 100 men and gives promise of a large business in the near future. It, apparently, is to be the regenerator of the early business prosperity of Dayton. And in consequence of this, a brief history of the mill may be interesting to our readers. The mill was built in 1865 by Mr. Fred. Birdsall in company with Mr. Carpenter. The first building erected cost \$106,000. Shortly after an addition was made, costing \$100,000, making the entire cost \$206,000. It was built as a quartz mill, having 30 stamps. It started up on Chollar ore, and afterward worked ore from the Occidental and other mines. Its best run was 2,700 tons of Occidental ore in one month. It ran about four years on ore, working over 68,000 tons. In 1870 it was changed to a tailings mill, and has averaged since then 50,000 tons per year. Its best run on tailings was 90,000 tons in one year. It is claimed that no other mill on the Pacific coast can show as much work accomplished. A reporter of the Times had an interview with Mr. Birdsall, the principal owner of the mill, last Thursday and learned from him the following: The company are now purchasing all the ore they can secure. In case they obtain a sufficient amount they will at once put in 30 stamps and engage in the business of ore crushing. They do not propose to do any custom work, but will purchase at a certain per cent. of assay value all ore offered. A smelting furnace will be built as soon as it is shown that sufficient paying ore can be obtained. The company will have a wood drive of 4,000 cords here in two weeks. In future they expect to use 5,000 cords per year. Mr. Birdsall and Superintendent Scott started out on a business tour the other day. They will visit Hawthorne, Belleville and Candelaria with the purpose of ascertaining, in a measure, the amount and quality of ore that might be obtained from those localities. We believe Dayton is on the eve of a grand business boom.—True Fissure, June 11th.

### Industrial Progress.

The largest cotton seed mill in the world is now in process of erection at Little Rock, Ark. It will work up 300 tons of cotton seed daily.

It is estimated by good judges that the mills of Minneapolis will grind the present year 20,000,000 bushels of wheat. The increase in milling capacity has been growing every year, but at no period so fast as at present.

The Director of the Mint estimates the total gold circulation at \$520,000,000, of which \$246,000,000 is in the Treasury.

The Agricultural Department estimates that 4% of the acreage of Texas can produce enough cotton to supply the whole world.

#### Foreign Industrial Notes.

In India there are 1,500,000 laborers engaged in the cultivation of jute, where it is spun in nearly every cottage. With our millions of acres well suited to jute culture, we ought to do a thousand times better than that, without becoming Indians. The fact is that jute culture and manufacture are two of the great prospective industries of our time and country; and the sooner the prospective becomes the realized the better. California is already moving in the matter.

The depression of agricultural interests in Great Britain is a more serious danger than the threatened approach of the combined armies of Europe or the disturbances in Ireland.

Eight factories in Tarapaca, Peru, produce annually 350,000 pounds of iodine. Three other factories are being constructed. The iodine is extracted from the waters of salt-petre.

The Chinese have 6,982 ocean vessels, with an aggregate tonnage of 4,353,696 tons.

Foreign financiers say that the gold exportation has very little effect on business.

A NEW WHITE LEAD PROCESS.—The production of white lead has given rise to various processes and improvements, one of the most recent of the alleged improvements in this line being as follows: Very fine ground litharge is subjected, in a mixing vessel, to a salt brine, by the action of which chloride of lead and caustic soda are produced. This mass is then run into an iron vessel, into which carbonic acid is pumped, causing a further chemical change in the production of carbonate of lead and common salt once more, and the latter, being washed out from the white lead, may be used over again in the first operation. It is stated, however, that though the article produced in this way is very white and chemically pure, it is somewhat less heavy than that made by the old process.

## MECHANICAL PROGRESS.

## Anomalous Action of Leather Belts.

According to the latest experiments of Mr. Samuel Webber, of Manchester, N. H., with leather belts, the following apparent anomalies were demonstrated by actual experiment: The belt developed in each case 90° of angle of the pulley-face, and was three inches wide. An old belt, moist, would hold on an 18-inch pulley 12½ lbs.; the same belt, drier, on a 24-inch pulley, 9½ lbs.; an new belt on a 24-inch pulley, 9½ lbs. These belts held in each case 2½ lbs. on one end, and at the other as much weight as was possible without slipping. Hence, the tension may be taken as equal for each case.

How does it happen that an old belt on an 18-inch pulley will drive 30% more than the same belt a little drier will drive on a 24-inch pulley? Why is it that a new belt on a 24-inch pulley drives, in these experiments, 33% less than an old belt on an 18-inch pulley? Where is the lost power due to bending belt more on the small pulley?

If, as some assert, the condition of the belt makes 30% differences in its driving power, if putting the grain aside instead of the flesh side to the pulley makes another 30% difference, what is the driving power of a belt calculated by a pocket-book formula, which quietly ignores their existence as factors altogether?

There seems to be an anomalous action here, unless we have overlooked some element which we do not now discover. Belts are very perplexing in their action in many instances, and this is not simplified by the diverse views which are held regarding them.

Another set of experiments, made by M. Lelontre, also furnish some further anomalous facts on the transmission of power by belts, described as follows: While the elongations or successive increments of length become less and less up to a certain load, they then become greater and greater, showing a point of maximum power of resistance which is then followed by a falling off. After this decline of resistance the elongation again becomes less rapid up to the breaking strain, on approaching which the resistance is generally greater. Practically, in the case of ordinary leather, the maximum resistance to stretching is met with at a strain of about 550 lbs. per square inch, while in India-rubber and webbing it occurs at rather a lower strain, the fact appearing, therefore, that the working strain on a belt should be fixed as near as possible as that to which the maximum resistance to stretching is known to occur.—*Journal.*

## American Mill Machinery in Europe.

The editor of the *Chicago Times* at London writes that the exhibition of mill machinery, which opened in that city a short time since, comprised over 100 exhibits, among them several from America. Plant's apparatus excited the greatest attention among practical millers, but more especially among the London newspapers, many of which never mention the United States except under the most extraordinary circumstances, when they cannot possibly avoid it. Such is the superiority of American machinery that great alarm has been created among English millers, many of whom have on exhibition old-fashioned millstones under the impression that they are the most modern improvement. The journals point to this superiority as the reason why Americans are able to come into the English market and sell better flour at a lower price than flour made by British millers. The importation of flour has grown from 6,000,000 cwt. in 1875 to nearly 11,000,000 cwt. in 1880, of which 7,000,000 cwt. came from the United States. The *London Times* comments on this increase as a startling fact, and says there is every indication it will continue to increase in the same proportion. The *Times* adds, after commenting on the superiority of the American system of milling and the number of mills in operation, that "on all sides the aspects of the situation are serious. English millers look with apprehension to the not very distant time when the vast imports from the United States may be mainly, if not wholly, flour instead of wheat. A most significant feature of the stride made by Americans toward eclipsing all Europe is the quality of their flour. The economy and perfection of their grinding, warn English millers that their success depends on the lessons they obtain at the present exhibition, and the uses to which they put them."

**A DANGEROUS PRACTICE.**—The dangers of meddling with defects in steam-boiler fittings, or with leaks, when pressure is on, are not fully realized by a great many. If plugs leak, or seams want calking, it is not safe to do it until the full working pressure is used. Wait until night, or better still, take time by the forelock, and as far as possible keep ahead of such contingencies by repairs at the proper time. The engineer of a portable mill at Aldrich, Minn., recently undertook to stop a leak in the boiler by screwing up a plug, which blew out into his face. Being on his breast under the boiler he was unable to escape, and was so badly scalded that he died on the following day. While calking a boiler at Easton, Madison county, N. Y., E. S. Vine was seriously scalded about the head and chest by escaping steam.—*Mechanical Journal.*

## The Hammer.

Taking as its text the ancient legend of the Mechanics' Associations, "By hammer and hand, all arts do stand," the *Economist* pays the following glowing tribute to this implement of industry:

The hammer is the universal emblem of mechanics—those skilled in uniting and binding together of materials. With the hammer are alike forged the glittering sword of contention, and the dusty plowshare of peaceful agriculture. Its workmanship ornaments the trapping of war, and nails the olive branch of peace above the gate. In ancient warfare it stood pre-eminent, apart from the instruments it wrought and formed. The old hattering-ram of the Greeks was nothing but the rude conception of a huge hammer. In heathen mythology it was always the symbol of might and strength. It was the sole weapon of the dreaded god of thunder, Thor, the mighty rival of Odin. His hammer was fashioned by cunning dwarfs, and possessed the wonderful property of returning to his hand after being hurled. To the heathen of Teutons the sign of the hammer was analogous to that of the golden cross of Christianity. In the hammer lies the wealth of a nation. By it are forged the ponderous engines that almost shake the world, and the tiny needle which unites alike the costly silks and satins of a queen, and the rough homespun of a laborer.

The hammer, too, is no partisan. It is an instrument of the savage and the civilized. Its merry clink points out the abode of industry and labor. Its handle if extended, inviting all to grasp, and with its unyielding head, by the help of a strong arm, forges happiness and prosperity. It is, in fact, a domestic deity presiding over the aspirations of wealth and ambition. Not a stick is pointed, not a house is built, a ship floats, or a carriage rolls, or a wheel spins or an engine thunders; not a press speaks or a hagle peals, a spade delves or a hammer floats, without having endured the blows of the hammer. So it instructs and teaches us that great ends and large results can only be accomplished by good, hard, vigorous blows. That if we would attain usefulness, and reach the full perfection of what we are capable of becoming, we must not shrink back from the hardships, buffetings and hard knocks of life, but early learn to cultivate the power of patient endurance.

**SAND IN WELDING.**—A correspondent of the *Blacksmith and Wheelwright* writes: "I wish to say a few words with respect to the use of sand in welding. The question seems to be shall we or shall we not use sand in making welds. I consider it a very essential point in working steel, and use a composition which I prepare as follows: Take a quart of quartz sand, one pint of common salt, one pint of pulverized charcoal, half a pound of horax well burnt. These I mix well together in a sand box, and consider the preparation much better than raw borax for working steel. In working iron I omit the horax from the compound. It is the best thing I ever used in facing hammers; and right here let me say a word about facing hammers: I draw out a piece of cast steel about one-quarter inch square, draw out the end to a square point and cut it off about one inch long. I make enough of these points to cover the face of my hammer. I then drive up my old hammer square on its face and take a square, sharp punch and punch as near the edge as practicable, and drive the pointed plugs in the hammer as fast as I punch till I fill the face. Drive them in till they project but half an inch, and then weld solid with light blows, first with hand hammer and follow with the sledge. Dress up and temper a light straw color."

**STEEL.**—The *Boston Journal of Commerce* objects to the very miscellaneous application of the term "steel." The "low steel," "mild steel," "Bessemer steel," and other names by which partly converted iron is known, ought not to be called "steel." The name is a misnomer, and it has recently been earnestly advocated at a meeting of manufacturers in England to propose and introduce a new nomenclature which should more definitely designate the different qualities of iron in its commercial form to steel in its various grades, and as adapted to various uses. It would be well if such a recommendation could be universally adopted and generally acted on. At the present the public is greatly misled by the use of the term "steel," in designating the substance of which razor blades and railway rails, surgical instruments and steam boilers, pocket knives and Krupp's guns are made, as though the same material were used in one and all. Nothing could be more misleading. The steel plates of a boiler or ship's side have no more in common with the plate steel from which saw blades are formed than nickel has with copper. And many other illustrations might be given to show the great divergence of the same quality held in common, and the number of qualities not possessed in common by the material coming under the single denomination of "steel."

**A BLACKSMITH'S FIRE.**—A correspondent of the *Blacksmith and Wheelwright* inquires how he shall keep his fire in a small compass. He complains that clay or mortar soon burns out. The editor says in reply: "If he will mix them with a strong salt brine he will find this trouble avoided. When he requires an intense heat I suggest that he use fine coal wet up with the same. Use a thin coating on top and around the fire. Salt and sand mixed and thrown on top of the fire is also good for the purpose."

## SCIENTIFIC PROGRESS.

## Storage of Electricity.

## A Wonderful Alleged Discovery.

A correspondent of the *London Times* makes an announcement which, if fully borne out by the facts, is of the highest possible importance. He states that M. Camille Faure, a noted French scientist, has discovered a practical means of storing electricity and rendering it portable. It is almost unnecessary to remark that nothing of the kind has been possible heretofore, and that it has been regarded as being impossible to store up electric energy in a practical manner. At a recent public séance of the Société d'Encouragement pour l'Industrie, presided over by the president of the French Academy of Science and attended by many leading English scientists, the success of the discovery is said to have been demonstrated beyond the possibility of a doubt. A Faure battery was charged with the electric fluid direct from the ordinary Grove battery. The receptacle consisted of four Faure batteries, each about five inches diameter and 10 inches high, forming a cylindrical leaden vessel, and containing alternate sheets of metallic lead and minimum wrapped in felt and rolled into a spiral wetted with acidulated water, and the whole placed in a square wooden box, measuring about 1 cubic foot and weighing some 75 lbs. This was protected by a loose wooden cover, through which the electrodes (in lead) protruded, and were flattened down for convenience of transport. This box was handed to the writer of the letter in question, who left Paris on Tuesday night, arrived in London on Wednesday, and finally reached Glasgow, where the box was presented to Sir William Thompson.

That eminent man is now experimenting with the box in the laboratory of the Glasgow University, and will no doubt give the world the benefit of the results of his tests at an early date. There the matter rests at present, but if all this be true there is no doubt that we are on the eve of changes which will completely revolutionize many of our existing appliances and processes, especially as regards lighting and heating. This small box, measuring about one cu. ft., is said to contain a power equivalent to nearly 1,000,000 foot-pounds—a force, of which we can only speak comparatively, and without adequate knowledge of the resources of the plan on a larger scale. It is plain, however, that if electricity really could be stored and safely conveyed from place to place we might look upon the future of illumination, by that means, as being thoroughly and completely assured.

At present the great drawback lies in the circumstances that the generation of the electric force and the production of the light are quite simultaneous. When the machine stops, the light disappears, and vice versa. If, then, some means be devised to intercept and store up a portion of the whole of this force for subsequent use, the difficulty would disappear, and electricity will take rank as a handy, manageable and unequalled means of illumination. The mere supposition opens out a vista which cannot be successfully thought out or described, seeing that, for domestic, railway, mining, manufacturing and scientific purposes, the electric current would indubitably replace gas and all other illuminating media. Before counting these as accomplished facts, however, many economic and other points must be satisfactorily explained. The outcome of Sir Wm. Thompson's investigations will be awaited, therefore, with more than ordinary interest.—*Ironmonger, May 21st.*

## Later Advances.

A London special to the *New York Times* of June 11th, and written nearly three weeks after Mr. Thompson's attention was first called to the matter, says:—"The matter of storage of electricity by the use of the Faure battery has attracted the universal attention of the scientific men of Europe. As has been previously stated, William Thompson, the eminent scientist of Glasgow, lately took from Paris to Glasgow a Faure battery, supposed to contain a power to the amount of 1,000,000 lbs. to the cubic foot. After some weeks, Thompson makes a report, in which he announces the perfect success of the effort to store and transport the electric power. He has already ascertained enough regarding the qualities of the Faure reservoir to make it quite certain that it solves the problem of storing electric energy in a manner and upon a scale to render it useful in many important practical applications. Among other uses, enough can be stored to give light in a house for several hours without an additional supply. The reservoir can be moved easily and used where the dynamo-electric machines are unavailable. One great advantage to be found is in the fact that when this energy is supplied from a Faure reservoir it is always steady in delivery, thus preventing fitful oscillations in the light, experienced from the unequal action of the ordinary dynamo machines."

**A LUMINOUS TELEPHONE.**—Design and Work is informed that some one in Leipzig has invented a telephone which reproduces words in luminous characters, capable of being photographically recorded; but they state that they want to know very much more about this invention before receiving it with "our childlike faith."

## New and Curious Properties of Metallic Salts.

At the Physical Society of London, Prof. J. H. Gladstone exhibited, recently, an interesting experiment showing the crystallization of a metal upon itself from a fused salt. Dr. Gladstone and Mr. Alfred Tribe, in the course of some experiments on metallic replacements, observed that some sheet silver placed in fused silver chloride, became quickly studded with crystals of the metal.

The displacement of a metal by itself seemed so anomalous that they at first supposed the silver employed to contain impurities; but such was not the case, and they farther found iodide of silver could be substituted for the chloride with a like result. Moreover, when copper was immersed in fused cuprous chloride, zinc in melted zinc chloride, or iron in fused ferrous chloride, crystals of each of the several metals separated out. That this remarkable phenomenon was not due to a different physical condition of the rolled metals was proved by putting crystals of the pure metal, separated by electrolysis, instead of the rolled metal, when fresh crystals were formed as before.

Subsequent experiments went to prove that the effect is really due to an electric current set up in the cell by the unequal heating of different parts of the metal plunged in the salt. This contact current was proved to exist by means of a galvanometer, and the two following experiments intensified the electrolysis. Some silver chloride was fused in a hard glass tube and a rod of silver placed in it. On heating the under side of the lower end for ten minutes, a considerable crop of silver crystals was found in the cooler part of the liquid. Again, some silver chloride was fused in a crucible and one side more strongly heated than the other. Two rods of silver were connected together, one in the hotter and the other in the colder part of the salt. At the end of 15 minutes the latter was found studded with crystals, while the former was clean. Copper wires immersed in cuprous chloride gave a similar result.

## Ozone.

Ozone was discovered by Schonbein 25 years ago. He gave it the name of ozone, which means smell, because he first ascertained its presence in his laboratory by its odor, which is something like that of phosphorus, noticeable sometimes, immediately after very loud thunder and vivid lightning. Schonbein had observed the same odor some years before, in 1840, at the positive pole of a platinum battery, used in decomposing water by electricity, and the same afterwards in the slow combustion of phosphorus and ether.

The presence of ozone in the atmosphere may be ascertained thus: Starch a piece of soft paper or muslin and dip it into a solution of iodide of potash, then expose it to the air; it turns brown first, and, when moistened, gives various shades of a pinkish blue, more or less deep, according to the greater amount of ozone contained in the air; a scale has been made of 10°, showing the relative amounts of ozone, with the accuracy of a thermometer measuring the degree of heat or cold. The principal European chemists consider that a more accurate and sensitive test of the presence of ozone in the atmosphere is made by saturating strips of paper with the tincture of guaiacum.

If the air contains one fifty thousandth part of ozone, its odor is perceived, and yet so delicate is the test of the scale, that four degrees lower its presence is manifest. If one five thousandth part of ozone is in the air breathed, insects die, by being consumed—burned up; for, as oxygen is the great oxidizer in the universe, and ozone being an electric or more powerful or concentrated form of oxygen with greater freedom and perfectness, it may be considered the fire of fire to all insect life. Although so little ozone in the atmosphere is required for health, yet, as this proportion diminishes, epidemic diseases are sure to appear; this has been repeatedly noticed by scientific men, from which the inference may be safely drawn, that the less ozone there is in the air, the more full it is of that kind of life which corrupts the blood; while the larger presence of ozone destroys this life, and we say "the air is so pure and lovely."

**DOES IRON EXPAND ON PASSING FROM A LIQUID TO A SOLID?**—This question was discussed at the late meeting of the Iron and Steel Institute, of England. The discussion grew out of a paper read by Mr. Charles Markham, of Stavely, on "Experiments made to Determine Certain Physical Properties of Cast Iron." He stated that an opinion had long prevailed that molten iron, in passing from the fluid to the solid state, expanded after it had been cast and before it commenced to contract; and it had been frequently stated that the excellent impressions obtained from the most intricate patterns were principally due to this cause. He doubted whether cast iron when passing from a liquid to a solid state did expand in the slightest degree; and he undertook a series of experiments to elucidate this position. These experiments clearly proved that the reason why a piece of iron rose to the surface after it had sunk through a mass of molten iron was entirely due to the film of iron, which increased the volume sufficiently to enable it to float on the surface. His conclusion was that no expansion took place in cast iron after the metal had been run into a mold.

#### The Mining Share Market.

The mining share market has been rather weak for some days. The quietness of matters on the Comstock, and the non-appearance of any bonanza, keep the market from any upward tendency. The *Enterprise*, notwithstanding, says: Again we have reached a point where we may with good reason expect to see advances that will outweigh the recessions; or, in other words, a gradual rise in prices may now be looked for. An advance upon present prices is warranted not only by the general favorable condition of affairs in the leading mines along the lode, but also by promising improvements at several points.

The east crosscuts on the 2500 level of the Sierra Nevada mine will be nearing a point where we may reasonably expect to hear of ore being encountered. The material in the bottom of the joint Sierra Nevada and Union Con. winze, now nearing the 2700 level, is of a very favorable character, and is steadily improving. Although there is no particular change in the appearance of the material in the bottom of the joint Ophir and Mexican east winze, a change may be looked for ere long. The present stratum of bird's-eye porphyry cannot last forever. As it lies very flat, not very much more material than constitutes its real thickness is being cut through. It is hoped that this great core of bird's-eye porphyry will be found to have compressed the ore-bearing portion of the material of the vein into a degree of compactness favorable to fertility. Although few persons appear to be giving heed to the fact, an east crosscut is already in progress on the 2700 level of the Ophir and Mexican mines that is liable soon to reach something of value.

THE STATE BAG FACTORY.—The State will soon attack the practical part of its bag making enterprise at the State prison at San Quentin. A correspondent of the *San Rafael Journal* gives the latest information on the subject. It says that the new factory is a building 240 ft. long by 140 ft. wide, of brick, one story high with concrete floor, to hold machinery consisting of 100 looms and 44 other machines, such as spinning frames, dressers, warp winders, dry spinners, dampers, measurers, sack cutters, and finishers. All these are for the manufacture of jute burlaps from the raw material, which at present must be imported from Calcutta, and of which 500 tons have already arrived and are in store at San Francisco. The building now in course of construction, will have an inside frame work of heavy trussed timbers with gable roofs, running laterally, and to be covered with tin. The machinery, which has been manufactured in England, is due at San Francisco the latter part of this month, and there is no doubt but that by the last of September, the factory will be in full operation and giving steady work to 400 prisoners.

#### New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department No. 10, San Francisco:

BLINN LUMBER Co.—June 22d. Object, to deal in lumber, building material, etc. Capital stock, \$150,000. Directors, L. W. Blinn, O. G. Goodhue, F. E. Hooper, C. A. Hooper, George W. Hooper.

LITTLE PRINCE M. Co.—Location: Cache County, Arizona. Capital stock, \$1,000,000. Directors, A. S. Allen, J. H. Helm, J. L. Homer, Wm. Hazlehurst, H. H. Rockwell.

PINAL CON. M. Co.—Location: Pinal county, Arizona. Capital stock, \$100,000. Directors, S. Linkton, H. N. Noble, F. Loran, S. Hart, Henry Donnelly.

ZONK G. & S. M. Co.—Location: Yavapai county, Arizona. Capital stock, \$10,000,000. Directors, R. Bernhardt, H. G. Cuhl, H. T. Graves, F. H. Simon, D. S. Griswold.

LIMA CON. M. Co.—Location: Arizona and Mexico. Capital stock, \$2,000,000. Directors, R. D. Fowler, C. J. Greene, W. H. Fowler, Charles R. Brown, Joseph T. Fisk.

#### The Coming Fair.

A meeting of the Board of Managers of the Sixteenth Industrial Exhibition was held on Tuesday evening last. It has been decided to change the interior of the building from last year, by having two main aisles running from Mission to the center, and one from Market street. The machinery will be partitioned off from the main hall, thus giving the music a better chance. The number of applicants for space is now in excess of last year. To encourage inventive talent, an "Inventors' Gold Medal" is offered for the best recent Pacific Coast invention, the award to be decided by a committee of acknowledged mechanical ability. The art gallery will contain greater and more attractive features this year than ever before shown at these fairs, the particulars of which the managers are not yet ready to announce. Bids for music from

few first-class mines would be added to those now being worked. Like farming or any other productive industry which requires patience, perseverance and economy, to make it a success, so is mining.

#### NEVADA.

**LITTLE YORK.**—Nevada Transcript, June 10: Dean Colburn is about to reopen the Siderich drift tunnel. Bludmer & Hotzinger are making a 20-day run to their hydraulic claim. Seth Martu is doing well at his Mt. Oro drift claim. He is reported to have recently found some very fine specimens, including one that weighed 7 ounces. The incline of the True Blue mine, owned by Nevada City parties, on Friday struck bedrock on what is supposed to be the east rim of the channel for which they have been sinking. Gravel was struck in the tunnel of the Wind-up drift mine lately before last, and some very good prospects obtained. The tunnel is in nearly 1,400 ft., and we believe shows a color for the first time. The Wind-up is a Grass Valley company who have spent a great deal of money in prospecting there. Some persons maintain that the channel—said to be a "blind" one—where they are searching, comes down the ridge from the Centennial claim in Washington township.

**SARGENT & JACOBS MINE.**—Nevada Transcript, June 17: Twelve men are now employed in Sargent & Jacobs' drift mine at Quaker hill. The tunnel is now in 600 ft west from the shaft. A drift going south is to be started this week. The gravel in the present breast is looking fair.

**WASHINGTON MINE.**—Grass Valley Union, June 20: For some time the drifts on the 25 level of the Washington mine have been extending to the north and south of the shaft without satisfactory results, as the quartz did not make into a permanent and compact vein. Lately it was determined to crosscut into the foot wall, at a point in the south drift where quartz stringers seemed to be going in that direction, and after driving a few feet through very hard ground a strong ledge was struck into on Friday night, but owing to a heavy flow of water its thickness has not been determined. As the water is now under control the width of the ledge will soon be ascertained. It is said to be a compact vein of fine-looking quartz.

**APPOINTMENT.**—Mr. E. M. Sunderland, of North San Juan, has been appointed special agent of the State Miners' Association, and will soon visit all the mining districts of Nevada and adjoining counties with a view to increase the membership of the association.

**NEW YORK HILL.**—This noted quartz claim, on New York hill, is again turning out rich specimens of rock of the kind that has to be gathered up in boxes and stored away until it can be mixed with a poorer quality of rock for crushing. This rich quartz is being taken out by John Ford & Co., the lessees of the mine, and is about of the same bonanza quality as that previously taken out.

**GOOD QUARTZ.**—Thomas Scadden has been prospecting for some time on the quartz claim on Rhode Island ravine, between the Seola mine and New York hill, and at the depth of between 35 and 40 ft, has struck a ledge from 6 to 10 inches in width that shows well in free gold. All the rock that has been taken out is of good quality, and there is reason to hope that the find will prove valuable.

#### MARIPOSA.

**FIRE MINE.**—Mariposa Gazette, June 18: Extensive preparations are being made to vigorously prosecute the work of this mine with an increase of power and force, double to that previously had, by building an additional 40-stamp mill, increasing the water power and penetrating the mine at greater depth, which will require a vast amount of lumber, machinery, labor and money. An expenditure of at least \$200,000 is contemplated by the company in constructing the new mill and making the improvements referred to. Mr. Bothwell, the superintendent, appears to be a man of fine executive ability, and is making a favorable impression with all who form an acquaintance with him.

**EL CARMINE MINE.**—This quartz mine is situated about 3 miles east of Hite's Cove. Like hundreds of other mines similarly situated at this time, it was discovered and worked on a limited scale by the poor, honest miner, who tenaciously held on to his small property, many years, waiting for a helping hand from capitalists, and waited until death relieved its discoverer of all anxiety. Several attempts have been made since to develop the mine by parties of limited means, which failed until the property fell into the hands of Mr. Robert Williams, of this place, who, with his own private means, developed the mine sufficiently to attract the attention of capitalists. The mine was sold to Mr. J. J. Dolan, a Philadelphia secretary and treasurer of the company, arrived last week. He started for Philadelphia on Monday, going by way of Quincy. The company intend soon to erect hoisting works so as to work the lower 300 ft of the shaft and bring the ore that distance to the tunnel, through which it will be run to the mill on cars. The 24 stamps are running uninterruptedly, and the appearance of the entire property is remarkably good.

#### PLACER.

**DRIFTING ON THE DARDANELLES.**—Placer Herald, June 18: The Dardanelles Co. has opened up several breasts in the ground over the Vigilance tunnel from which come some very flattering reports. Not more than 40 carloads per day are being taken out yet, but in a week or 10 days they will be taking out about 100. The yield at present is from \$23 to \$34 a load. Prospect drifts have been run back into ground that prospects from \$2 to \$10 a pan. Into this a bedrock tunnel is now being run and in about 30 days breast will be opened.

#### PLUMAS.

**CRESCENT.**—Greenville Bulletin, June 15: Indications are favorable for the starting of this mill, and reopening of the mine which has lain unworked for so many years. A great amount of gold has been taken out in the years gone by, and anyone who knows the mine is well aware that immense quantities of good ore can easily be obtained from it, as it has been but partially worked. **INDIAN VALLEY.**—Mr. E. A. Corbin, of Philadelphia, secretary and treasurer of the company, arrived last week. He started for Philadelphia on Monday, going by way of Quincy. The company intend soon to erect hoisting works so as to work the lower 300 ft of the shaft and bring the ore that distance to the tunnel, through which it will be run to the mill on cars. The 24 stamps are running uninterruptedly, and the appearance of the entire property is remarkably good.

**ARIZONA BRANCH.**—Plumas National, June 18: During the past week the noted mine belonging to Loring & Leavitt, of Elizabethtown, was sold to Corbin, Manson & Co., for \$50,000, cash. Negotiations in this direction have been pending for several weeks, but nothing definite had been arrived at until Wednesday, when the bargain was closed. The mine is paying splendidly, in fact better than ever, and the new owners will put on heavy machinery and work it much more rapidly than heretofore. There is but little doubt that it will prove one of the richest mines in northern California, and we wish to see new owners the best possible success. The former owners, Messrs. Loring & Leavitt, are to be congratulated on their good fortune, as in a few months they have amassed a competency, and can now take it easy for the balance of their lives.

**STRUCK IR.**—Mr. L. Bell showed us some very healthy looking nuggets on Tuesday evening from the Western claim, near Newtow, the result of a small washing of dirt. One or two of the pieces were an ounce or more in weight, and proved that they had found the pay streak which they have been prospecting for several weeks.

**EAST BRANCH IR.**—The East Branch miners are all busy at work, with fair prospects. Lazier & Co., on Indian hill, continue to work their claim very successfully, and have ground out enough to employ them for years to come. Messrs. Keay & Livingston, working the noted Irish crevice, leading from Indian har into the hill, are being richly rewarded for the efforts, picking up daily nuggets of good size, and anticipate a rich harvest of gold when they shall have reached the bottom of the crevice.

**YELLOW CREEK M. Co.**—This company has been for several years engaged in making a canal of great capacity to conduct the waters of Yellow creek, in Humboldt valley, to the banks of the North Fork or below Junction bar, and having completed the work have put into operation one first-class hydraulic chief. The extensive gravel banks along the North Fork, Yellow creek and Mosquito

creek, promise great results for this important enterprise. **FRENCH RAVINE QUARTZ.**—The work of developing this mine has been commenced by F. R. Whiting.

#### SIERRA.

**REWARD.**—Mountain Messenger, June 18: The Bald Mountain M. Co., on Tuesday, put 50 men at work drifting, at \$3 per day. These men have been at work on repairs since the 1st of the month. None of the old drifting force have yet been put on.

**AIR COMPRESSOR.**—The Savage Co. have put in an air compressor for running the drills in their tunnel. The distance to the face is such that before the steam reaches the drills there is much condensation.

**GOLDEN GATE.**—The name of the Oriental mine, Allegheny, is changed to Golden Gate mine, and is now owned ostensibly by a New York company. It is reported that work is to be commenced on it in a short time. From the fact that Benham was in town a few days ago, driving a span of fine horses, we infer that he is to be superintendent.

**STICKS ROBBED.**—The slaves of Wm. Planks, Eureka, were robbed not long since, the robbers getting well paid for their trouble. It is supposed that Chinamen did the job.

**PHOENIX.**—We are informed that the Beard Bros., of Sierra City, were recently offered \$125,000, cash, for the Phoenix quartz mine, Sierra City, but refused to sell at that price.

**AMERICAN M. Co.**, at Morristown and Craig's flat, will finish working about the 1st of July. The season has been a good one for them.

**THE DUTCH CO.'S** mine, at Logansville, J. T. Mason, Supt., is paying handsomely under the new management. Johnny can make a mine pay if anyone can.

**BLACK JACK.**—This mine is prospering, apparently. Carpenters have been at work some time putting in new machinery, and will finish their job in about two weeks more.

**RICH BOWLER.**—In Harry Richard & Co.'s mining claim, at Eureka, a quartz bowler weighing 9 ounces was found to contain nearly 5 ounces of gold. It was discovered by its weight.

**NO GRAVEL.**—The report that the Savage Placer Co. had struck gravel was not true.

**THE KUBLY** tunnel, Cariboo, is now in over 1,600 ft. Rock is still very hard. Progress made, about \$ ft per day.

**ITEMS.**—The Bonanza M. Co., of Howland flat, is paying finely at present. The Pioneer mine, at Grass flat, is looking finely. They will have water for some time yet.

#### SISKIYOU.

**EXAMINATION.**—Oregon Sentinel, June 18: Richard Cook, one of our mining experts, left this week for Siskiyou county to take a look at the quartz ledge of Messrs. Miller & Kime. Mr. Cook has been employed to make a thorough examination of the property and pass his opinion upon its value preparatory to opening the mine with machinery, etc.

#### TRINITY.

**CLEANING UP.**—Trinity Journal, June 18: Miners hereabouts and elsewhere in the county are now engaged in cleaning up their claims for the season, and it is probable that most of them will be done by the close of the present month. The season has been a short one, but good work was done while it lasted. Although we have not been furnished with any figures, the impression prevails that Trinity county mines will pay well this year. Certain it is that a great deal of gold dust is being shipped, and that is the best indication we know of the paying character of our gravel mines.

**STEWART.**—Stewart Gibson was in from Deadwood this week, and showed us a couple of specimens from his recently discovered ledge. Free gold was visible, and Stewart says he expects to find plenty more of the same character, as the ledge is large and well defined.

#### TUOLUMNE.

**NEW MINING CO.**—Independent, June 18: A Stockton company have organized themselves to work the old United States lot and others adjoining containing the Divoll Bonanza lead. The working shaft will be not much over 150 ft from that of the Bonanza. The line from thence passes across the flat under the Episcopal church to the opposite hill, and connects with the Colby or Big Bend claim. Under this contract, which provides a bonanza to many a miner in early days, got its main feed from this vein. Active operations have already commenced, and Vinc. Wooster, an old experienced miner, is the superintendent.

**NOTES.**—Mr. Eames has started up his 10-stamp mill on the Shaw mine. The new Toledo quartz mill is a success, and things are active about the mine. The Sonoma mine has let another contract, which when completed will make the depth attained in No. 2 shaft 125 ft. The ore is improving as depth is attained.

#### NEVADA.

##### WASHOE DISTRICT.

**CALIFORNIA.**—Enterprise, June 10: On the 2000 level the north drift from No. 1 winze has been extended 18 ft. Progress in this drift is 13 ft. On the 2500 level the joint Con. Virginia east crosscut has been advanced 19 ft, cutting out station for joint Con. Virginia winze.

**HALE AND NORCROSS.**—We are anxiously awaiting the starting up of the hydraulic pump at the Chollar-Norcross-Savage shaft, that we may stop our pump and make some repairs to the perpendicular shaft, which are absolutely necessary, and which cannot be made while our pumps are running.

**SIERRA NEVADA.**—During the week 350 tons and 200 lbs. of ore, assaying \$31 per ton, have been extracted.

**UNION CO.**—On the 2500 level the joint Mexican winze has been sunk and timbered 9 ft, and the joint Sierra Nevada winze 12 ft; also, have completed the tank station and placed the tank in position.

**CON. VIRGINIA.**—On the 2500 level the joint California east crosscut has been advanced 10 ft. Are cutting out a station for joint California winze.

**MEXICAN.**—On the 2500 level the joint Union Con. winze has been sunk and timbered 0 ft, and the joint Ophir east winze 11 ft.

**OPHIR.**—On the 2500 level the joint California winze has been sunk and timbered 13 ft, and the joint Mexican east winze 11 ft.

**ALTA.**—During the past week we have sunk and timbered the shaft 27 ft; total depth, 2,067 ft. The rock continues hard.

**UNION SHAFT.**—Cutting out station at the 2700 level and easing the timbers at the 1900, 2000, 2400 and 2500 levels.

**NEW WELLS-FARGO.**—Last Friday the shaft was cleared of water, but the bottom was found to be filled with debris above the drift from the shaft. The flow of water is as strong to allow of any effective work in removing the rock and earth which now obstruct the entrance to the drift. Most of this water is seepage, however.

**YELLOW JACKET.**—Since my last we have reached the 2825 station, and find the shaft and drift in good condition. We have placed two large donkey pumps at this station to raise the Belcher water to the 2800 tank.

**SUTRO TUNNEL.**—Three carpenters have been employed during the week finishing the drain boxes and making the connections. The small sub-drain leading from the Combination connection to the south lateral junction is now excavated for a total distance of 130 ft. Additional to the usual work along the main line, considerable repairs have been made this week on timbers in the main tunnel. During the week the repairmen have lowered the track at the Yellow Jacket work point for a distance of 100 ft, finished lagging up the carriage station and cut a small ditch from the turning point to the face; also, extending the second line of blower pipes to the carriage station and making the necessary repairs in the drift.

#### DUN GLEN DISTRICT.

**AUBURN MINE.**—Silver State, June 20: From J. A. Conlee, foreman of the Auburn mine at Dun Glen, an experienced and intelligent miner, we learn the following relative to the property. Mr. Conlee, upon assuming charge of the mine some three or four months ago, found two tunnels, each about 30 ft long, and running parallel with

each other, a short distance apart on the lead. These tunnels cut the ledge at right angles, but did not determine to any great extent its richness or permanency. In drifting on the lead from the old tunnels, he finds the ledge to be from 20 to 30 ft wide, as far as opened—some 120 ft. The ore is of high grade, and is estimated from a number of assays made that it will average \$40 to the ton. It is his intention to run this drift north on the lead to the surface, on the slope of the hill. In the new tunnel he has cut the vein 30 ft below the level of the old tunnels. The ledge is 30 ft wide, but the ore is generally low grade, not over 3 ft of it being up to the average in the drift from the old tunnel. As these tunnels are 800 ft apart on the line of the ledge, they establish its permanency beyond reasonable doubt. The ore in sight is sufficient to warrant the company in erecting a mill, and the intention is to commence grading for that purpose about the 1st of July. Twenty stamps will probably be put in the mill this summer, and its capacity will be increased to 40 or 60 stamps if the developments in the mine warrant the increase of the reduction works. The mine is located about 10 miles from Winnemucca, and the mill will be erected a few miles below the mine, in what has been known as Grass Valley country. The mine is owned by a number of mine, and large quantities of ore, extracted in running drifts on the lead, are on the dump.

#### ESMERALDA DISTRICT.

**THE HUMBOLDT WEST.**—Esmeralda Herald, June 18: There have been considerable improvements made in and about the mine since our last report. The ground around the opening of the shaft has been leveled off, and the ore dumps put in good shape. The Humboldt West is one of the biggest and best mines in Nevada, having, at the depth of 100 ft, a ledge 23 ft thick that will average not less than \$30 per ton. With a 90-stamp mill it would turn out in this neighborhood of \$250,000 a day.

**SILVER.**—The ledge in the Humboldt West on the north is the Silver Lining, on which is a strong ledge of good ore. Assays recently taken give flattering results.

**EVA COS.**—Three assays were recently made of ore taken from the shaft at a depth of 50 ft, with the following results, which show the lowest value per ton to be \$35.72, while the highest is \$52.63.

**THE KORTZ.**—The incline shaft last night reached a depth of 120 ft from the tunnel level, which makes the total depth from the croppings 233 ft. The ledge in the bottom of the incline is 10 ft thick, and the ore is immensely rich, with not a particle of waste rock mixed in. There is now on the dump about 150 tons of ore.

**THE CENTENNIAL.**—The ore being extracted from the upraise continues of the same high grade. The bottom of the incline is over 200 ft from the croppings, and the thickness of the ledge is the same, with the quality of the ore fully as good as not better than at any other point.

#### EUREKA DISTRICT.

**STARTED WORK.**—Eureka Sentinel, June 14: The Eureka (Nev.) M. & S. Co. started work on the Kit Carson mine, which was sold by the Eureka Mining Co. to the intention of the company to do a large amount of work this summer. At present the mine is looking well. **GEDDES & BERTRAND.**—This mining property was purchased a few weeks ago by Gilmer, Salisbury & Co. Since that time they have had a force of men employed in putting the mine in shape to do vigorous and systematic work. While thus engaged ore has been found in several places where it was not thought of looking for it. The ore now in sight will more than return to the owners of the mine the purchase money. The ore is of very high grade. We look for the Geddes & Bertrand mine to make one of the finest properties in the county. The new company are highly pleased with their prospects.

#### HIKO DISTRICT.

**TEST.**—Pioche Record, June 14: P. Vallejo left Pioche Saturday evening for Hiko, going there for the purpose of examining ore recently discovered. He will start the mill up to make the test, and should the ore prove sufficiently rich to pay expenses he will keep it running, but, if not, will at once close down the mill. Henry Raymond will shortly be back.

#### HUMBOLDT DISTRICT.

**SATISFACTORY.**—Silver State, June 8: Sol. Kunkle and Judge Barbee, of Salt Lake, have gone to Humboldt district, which is situated in the Humboldt range, east of Humboldt, and with the intention of engaging in mining operations. They visited the district two or three weeks ago, and took samples from several ledges, which they have assayed at Salt Lake. The results were so satisfactory that they have returned with the intention of developing some of the ledges from which they took the samples.

#### PARADISE DISTRICT.

**FAVORABLE.**—Silver State, June 18: Reports from the Paradise mines continues favorable. The ledge in the joint shaft which is being sunk by the Ballioli and Wild Goose companies continues large and rich. As the shaft is over 200 ft below the surface, it is now demonstrated beyond doubt or cavil that the ledge continues downward, and carries rich ore to an indefinite depth. The Red Dog Co. have recently made very important developments in a drift 90 ft from the surface. It is supposed to be the main ledge, which mining men have predicted would be found between the porphyry and metamorphic slate formations. Large deposits of sulphurates have been found in crosscutting the ledge, and that kind of ore is considered valuable for the production of sulphur. The Paradise mine, which is owned by W. Letts Oliver, Sec'y of the company, will shortly resume operations, and the attention of Eastern capitalists is being drawn to the district by the success of the Bullion and other companies which are prosecuting work. For some reason a determined effort has been made by certain San Francisco operators to bring the district into disrepute, though it has produced as much bullion as almost any mining camp in the State proportion to the amount of work done and money expended in developing the mines.

#### SACRAMENTO DISTRICT.

**ENCOURAGING.**—Silver State, June 20: Very encouraging reports continue to be received from Sacramento district, in the Humboldt range. It is said that if such prospects as are now being opened there were found in some local area away from railroads, it would cause a rush of miners to the camp; but as they are in an old, though unprotected district, they cause no excitement and attract no attention.

#### ARIZONA.

**NOT SOLID.**—Arizona Journal, June 16: The statement that the Total Wreck mine had been sold for \$800,000 proves, on investigation, to be wholly incorrect. The company owning the mine has been incorporated, and the stock is selling freely in the East for \$7 per share, or at the rate of \$1,400,000 for the mine. Civil Engineer Paul Ricker, of the Surveyor-General's office, recently made a careful survey of the workings of the Total Wreck, and his report, it is said, is to the effect that there is now no less than \$2,000,000 worth of ore in sight. As the grade of the mine is very high grade—\$80 to \$100 per ton, free milling at that—it will be seen that the Total Wreck is even now a bonanza of huge proportions.

**"NOVEL STRIKE."**—While prosecuting the work of development in B. P. Parker's well-known mine in Old Hat district—the Bonanza—a rather novel strike was made. It consists of a 12 to 18-inch vein of red ochre oxide of iron, or natural red paint. Some samples of the ore were brought in a few days since and left with Wetmore & Dean, the assayers on Meyer street north, and experiments made with them have resulted very satisfactorily. The stuff, which is about of the consistency of soft chalk, requires only grinding and mixing with oil to make a very excellent coarse red paint. Large quantities of this kind of paint is and can be made in Arizona, and Mr. Parker will find a ready sale for all the red ochre he can produce.

**OLD DOMINION COPPER.**—Globe Chronicle, June 16: Since last report there has been about 25 ft of tunnel run on the Old Dominion tunnel, and as work progresses the ore is found to be getting better, and a larger body than ever has been uncovered. Developments on the New York and Chicago are of a most satisfactory nature.

**WASHINGTON.**—The Supt., Mr. J. D. Larue, was in town last Monday, and reports favorably on this mine. The main shaft is now down 154 ft. The northeast drift on the 70 ft level is in 62 ft. The ledge, however, was tapped last Friday, which showed well. On the 152 ft level a station is being cut out for the purpose of cross-cutting the ledge.

**TRK EMLINA.**—This fine property, recently sold by Mr. J. L. Clark, to Messrs. Newcomb and Tabor, of Boston, is improving with every foot of development it receives. Work was resumed by the new ownership and under the superintendence of Mr. Clark last Thursday. The face is all in ore, and a strip of about 18 inches of the ledge is high grade, giving an average assay of over \$500 to the ton. The mine is being worked with day and night shifts. **N. R. COLONEL SURVEY.**—This magnificent property is on the right bank of the Pinal creek, about four miles below Globe. It is opened on the ledge, which is about four ft and a half wide, by a tunnel entering the hill toward the northeast, and is now in about 75 ft, and exposes one well which is as smooth and straight as any to be found in the district.

**MEX. SOLA.**—Pinal Drill, June 18: The Silver Bell Quartz for \$20,000, and the Columbia for \$10,000, both to Aaron Mason, for cash. We have frequently described these excellent properties. They are contiguous, and situated about 10 miles South of Pinal, toward the Gila river. The owners of the Silver Bell Quartz were K. Conn, H. B. Murray and W. Munton. The owners of the Columbia were Champion, Goodfellow, T. Farrell, W. Hapton and J. H. Cox. Two days run on the mine, and four days run produced \$1,100 at the Windsor mill, out of the tellings, and still they run. The expenses are about \$60 per day.

**SAN PEDRO DISTRICT.**—Pinal Drill, June 18: The San Pedro district, also in Pinal county, is 7 miles westerly of the San Pedro river. Here are the following mines: The Sample, Pioneer, Walston, Yellowhammer, Silver Chief, and Arizona. Two days run on the mine, and four days run produced \$1,100 at the Windsor mill, out of the tellings, and still they run. The expenses are about \$60 per day.

**PIONEER DISTRICT.**—Globe Chronicle, June 16: The Pioneer mine, owned by Mr. Geo. Scott, is on the same ledge with the Pioneer South, and with as much development will, in all probability, prove to be as good property. **MASKE.**—Messrs. Bibb, Wentworth and Pascoe, started last Tuesday for the Mahel mine, near El Capitan, where they have landed a large supply of provisions, with the intention of making a thorough development of this property. A rich strike was recently made.

#### COLORADO.

**DECATUR ITEMS.**—Georgetown Courier, June 16: During the past week, parties representing large companies in New York, San Francisco and other points have been inspecting our mines, and from what they say, one is led to believe that Decatur's day of prosperity is beginning to dawn. In no instance have they expressed disappointment; on the contrary, they were surprised that we have not got a larger number of capitalists among us. When you can find prospects only 10 ft deep that yield \$10 a day to the man, and ore that mills from 500 to 1,000 ounces per ton, it is considered by old miners good enough to go and complete the mine. Such is the state of the prospects are being worked, not with the intention of selling at the first offer, but for the purpose of developing and placing them in good shape. Confidence in the future is growing daily, not only with those who own mining property, but with capitalists and tenderfoot, also. Town property is steadily advancing, quite a number of new houses are being built and a large number of persons contemplate building during the summer. Work has been resumed on the Carraway, Fatal, Humburg, Woodbeam, Big Chief, Keithly, Argentine, High Line, Lilly May, and other lodes too numerous to mention, from one to four men being employed upon each of them.

**CASCADE DISTRICT.**—Georgetown Courier, June 10: A strike of 12 inches of 200 ounce ore was made last week on the Silver Ring. The Charter Oak lode, owned by the Leelanau M. Co., and worked by Roberts & Co., lessees, is making regular monthly shipments, the ore being dressed into three classes, which mill from 54 to 150 ounces of silver per ton. The pay vein is from 12 to 10 inches wide.

#### MONTANA.

**NELLIE GRANT M. Co.**—Helena Independent, June 14: This is a new organization or property recently bought by H. S. L. Sheard. The entire purchase consists of 8 locations on Red Mountain, comprising the Nellie Grant, after which the organization takes its name, the Treasury, Treasury No. 1, Good Friday, Gen. Sherman, Gen. Grant, Cannon and Cannon Extension. The price paid is \$120,000, and cheap enough at that. The Nellie Grant is estimated to be worth fully the amount paid for the entire group of mines, while Mr. Sheard is well persuaded that his company have the entire value of all they have invested in the Treasury.

**TRUCKEE.**—Little Jennie, of the Vaughan district, had ready for shipment to Wickes on the day the works were consumed, 60 tons of ore taken from the dump, which carried 82.61 ounces of silver and \$12 gold per ton. There are out about 60 tons of the best grade ore, carrying from 300 to 500 ounces, and 40 tons of second grade carrying from 125 to 150 ounces of silver per ton, now ready for shipment. The mine is estimated to have produced not quite \$200,000, under circumstances not at all favorable to the economical development of the property.

**THE BONANZA CHIEF.** M. Co. started their 20-stamp mill when their mine was less than 30 ft deep, but it has continued to run since that time when the water supply was sufficient. In what is known as the south drift, a level has been run for a distance of 110 ft, all the way in good ore, but it seems as if the progress has been made to attain depth and open up stopping ground. The first run of last month netted about \$11 in gold to the ton, and this ought to yield a profit and encourage a better development of the property.

**THE ALTA MONTANA CO.** has set every man in camp at work clearing away the rubbish from the grounds, preparatory to putting the new works in order. The superintendent thinks that within 30 days he will be able to start the water concentrator.

**A PERSONAL VISIT** to the Gloster mine, owned by the Boston & Montana G. M. Co., has more than confirmed our estimate of the property. Its situation for economical working is all that could be desired, and it possesses one peculiarity seldom found in any mine. The rock is so soft that whether work is prosecuted in the vein or country rock, which is granite, there is no need of blasting.

#### OREGON.

**APPROXIMATE.**—Oregon Sentinel, June 18: William Healy, one of the oldest miners of upper Applegate, spent a few days in town this week. Bill says "there are millions in it," if only the proper appliances could be brought to bear on it.

**NUGGET.**—Geo. Schumpf, the mail carrier, on Wednesday brought in a beautiful nugget of washed gold, weighing over 4 ounces. It was found a few days ago at the Collins & Thurman claim on Elliott creek, a point west of by last summer's freshet. The nugget was valued at \$81.12.

**WAGNER CREEK.**—Horace Seybert, of Wagner creek canyon, has lately been prospecting a quartz ledge which he discovered on the mountain dividing the waters of Little Applegate from the waters of Wagner creek. The quartz prospects \$30 (fine gold) to the ton of rock. Mr. Seybert thinks it is a good thing.

**WARNER RANCHO.**—Lakeview Herald, June 16: Considerable excitement is being created here over the appearance of quartz recently found in the Warner range hills. Somebody expects to strike a bonanza at no distant day within a stone's throw of town. Evidently there is an abundance of the precious metal in the hills hereabout, and all that is needed is enterprise with a little capital to develop some of the ledges already located.

### The Hydraulic Miners' Meeting.

The following is an Associated Press dispatch from Nevada City, dated June 18th, giving the particulars of the miners' meeting held at that place on that date:

The holding of the miners' mass meeting in this city to-night brought together a large and enthusiastic crowd of people from all parts of this county, and many from Placer, Sierra and Yuba. A delegation of about 50 men arrived from Smartsville, Yuba county, shortly before six o'clock P. M., and drove into town in procession. In the afternoon flags floated from all the flagstaves in the city, and in the evening, previous to the meeting, two hands discoursed music on the streets and in front of the hall, while an incessant and deafening firing of giant powder cartridges was kept up. Shortly after eight o'clock the meeting was called to order in the theatre by Hon. W. D. Long, who stated, in a few words, its object. Major J. S. McBride was chosen Chairman. The following Secretaries were elected: Permanent Secretary, J. E. Brown; Assistants, L. S. Colkins, of the *Transcript*, J. B. Gray, of the *Herald*, C. H. Mitchell, of the *Grass Valley Union*, and Rufus Shoemaker, of the *Free Lance*. The following persons were chosen:

#### Vice-Presidents of the Meeting.

W. D. Long, Nevada City; Jas. O'Brien, Smartsville; Thomas Mein, Blue Tent; J. B. Patterson, Little York; E. Coleman, Grass Valley; O. P. Stidger, San Juan; G. A. Allan, Nevada; James Marriott, North Bloomfield; J. Spaulding, Dutch Flat; James Gould, Gold Run; Chas. Haggerty, Moore's Flat; P. Nichols, Dutch Flat; G. W. Cumminge, Oroville; J. C. Coleman, Grass Valley; H. C. Perkins, Bloomfield; H. S. Brigham, Moore's Flat; R. C. Walrath, Nevada. Hon. W. D. Long introduced a resolution that a committee of three on resolutions be appointed, to whom all resolutions should be referred without reading. The following committee was appointed: Hon. W. D. Long, Hon. Niles Searle and R. McMurray.

#### A Pointed Address.

O. W. Cummings, of Oroville, was here introduced, and made some pointed remarks concerning the present state of affairs between the farmers and miners. He eulogized the miners and stated that they had made the State what it is, and not the farmers; the miners expected to prove that for every yard of debris they had deposited in the river the farmers had deposited 15. He urged the miners to put their shoulders to the wheel and help along their cause. The speaker was intensely listened to, and frequently applauded. The Committee on Resolutions here reported as follows:

#### The Resolutions.

To the citizens of Nevada and adjoining counties, in mass meeting assembled: Your committee, appointed to draft and present resolutions expressive of the sense of the mining community regarding the pending litigation by the city of Marysville against the hydraulic mines, beg leave to report as follows:

Whereas, Mining is the present industry of the Pacific coast, and through which our State was mainly settled, and by which every other interest has been vitalized and built up;

And whereas, the millions of gold annually yielded as the out-put of hydraulic mining can only be received by turning the debris arising therefrom into the mountain canyons and ravines;

And whereas, the city of Marysville, in derogation of an implied compact to await a solution of the drainage problem, is prosecuting an action against the hydraulic miners, and has caused an injunction to issue restraining such miners from prosecuting their legitimate calling, and which, if persisted in, and if successful, must eventuate in the entire destruction of our property values, and in the impoverishment of our people; it is now, therefore, by the miners and citizens in mass meeting assembled:

Resolved, That most of our mining property is held by patents from the Government of the United States, and having been purchased for the express purpose of mining by the hydraulic process, was taken and is held under an implied license to use it in the only available manner.

Resolved, That we most sincerely regret any injury which has or may result to Marysville, or the agriculturists in its vicinity, from the effect of mining debris, and that we have been and still are ready to assist by every legitimate means known to science in averting the evil consequences to them from mining operations.

Resolved, That the drainage scheme inaugurated by the Legislature offers, we firmly believe, a plan for the intelligent and successful solution of the vexed question; a solution alike beneficial to agriculturists and miners.

Resolved, That litigation cannot stop, that injunctions cannot restrain, the mass of mining debris now in our mountain streams, and which eventually must engulf Marysville unless arrested by intelligent and united action.

Resolved, That by 30 years of encouragement, by the payment of taxes and by a recognition of our industry in an endless variety of forms, we have acquired a vested right to the legitimate use of our mining property.

Resolved, That the attack upon hydraulic mining is but the entering wedge to a scheme which, if successful, has for its object the destruction of all mining property and every interest connected therewith.

Resolved, That for the purpose of protecting ourselves and those dependent upon us in the enjoyment of our homes, we will hand ourselves together, and by every effort which free men

may legally make we will battle for our rights and dare to defy those who would wrest from us the privilege of enjoying our hard-earned property.

Resolved, That we invite the co-operation of every citizen having the welfare of the mining region at heart.

Resolved, That the thanks of this meeting are hereby tendered to the Miners' Association for its stalwart efforts in behalf of our interest, and we hereby declare our unflinching confidence in the wisdom of its proceeding, and pledge to its support and maintenance such pecuniary aid as it wants and our ability will permit.

Resolved, That we deprecate as unjust and oppressive in the extreme the use of the extraordinary remedy of injunction to stay the exercise of a great industry, in which millions of capital have been invested.

Resolved, That we recommend all hydraulic miners to employ no Chinese laborers.

#### The Speakers.

Hon. Niles Searles was then called for, and came forward. He delivered a very eloquent address to the assembled crowd, and stated in a most conservative and impressive manner how matters stand between the mining community and the Grangers. He said that every man in the mining community had a duty to perform, and that a united effort was all that will secure victory for their cause.

Mr. Skidmore, of the Miners' Association, was next called, and responded in a speech in which he gave important data concerning the cost of the mining suit, and the objects and actions of the Association.

C. W. Cross made some pointed remarks. He disapproved of "boy-cotting" by the miners in refusing to patronize the farmers, but thought the proper way to settle the difficulty was through the courts.

During the entire meeting the heat of order prevailed. The speakers were listened to attentively, and although the applauding was loud and enthusiastic, nothing of a hoisterous nature occurred. A band of music enlivened the meeting by rendering several selections during the evening. As a mass meeting, it was the highest ever held here, the number present being estimated at about 1,000.

### Production of Arizona.

The Tombstone *Epitaph* says: Arizona is so new a mining field that all doubts as to its stability are not yet removed from the minds of the great operators in San Francisco. These doubts are, however, in a rapid state of dissipation, owing to the continued favorable reports from all parts of the Territory. The monthly hullion shipments from the various paying mines are the solvents that will finally work an entire revolution in public sentiment in a quarter that has been the centre of the mining industry since inaugurated in 1849. When the last doubts shall have been removed, as we predict they will be within the next six months, as many eager investors from the Pacific metropolis will seek this field as ever did the world-famous Washoe and the White Pines of Nevada, then will begin an era of prosperity of which the present is but a faint prophecy. That Tombstone will remain the chief factor in the solution of this problem, as she thus far has been, there is little cause to doubt. All well posted mining men in and around this place concur in the opinion that present developments are merely superficial and do not reveal a tithe of the wealth that is stored up in the rock-ribbed hills in this vicinity. As it is, there is a healthy, steady increase in the monthly returns from the mines, which promises to be kept up until a million dollars will not more than cover them. The last month showed \$50,000 more than the preceding. When Empire, Girard, Sulphure, Flora Morrison and Ingersoll, all of which have large bodies of ore in sight, start upon regular reduction, it would be apparent that the present yield will be more than doubled. As it is, the output for the month of May makes a good showing for a camp little more than two years old. The aggregate foots up \$481,803, as against \$430,000 for the preceding month. At this rate of increase the month of June should give \$530,000. From the outlook now the production for the present year will fall little, if any, short of \$6,000,000, as against \$4,500,000 for the balance of the Territory. It is to such facts as these that we confidently look for removing the last lingering doubt in the minds of the San Francisco capitalists.

### Grid-Ironed.

The Territory of Arizona, which was, until quite recently, a stranger to railroads, is about to be grid-ironed by them. Two great through lines from ocean to ocean traverse the extreme south and north of the Territory. We hear of another line running to Guaymas. The Utah Southern is headed in this direction, and soon we may expect it within our borders. The Southern Pacific are about to commence another line from Mohave in California, and we predict it will be extended to the Colorado river, and thence to southern Arizona, connecting there with their line, taking in important mining camps in Mohave, Yavapai and Maricopa counties. Again, Prescott is to have a branch north, to connect with the Atlantic and Pacific. It is also probable that a road will be built from Prescott to Phoenix. Surely we are to live in a land of railroads, and for northern Arizona, Prescott will be the great center. —*Arizona Miner*.

### The Oleomargarine Wrong.

The Oleomargarine-abomination is still exciting Eastern producers of genuine dairy goods, and well it may, for the length, breadth and depth of the false product seems almost beyond measurement, and its future difficult to define. The State of New York, which is most grievously afflicted, has passed another law, which will come into effect next month, and which it is hoped will accomplish what the older law failed to do, and that is the enforcement of plain brands, etc., on oleomargarine products, so that they cannot be passed off upon unwary buyers for true butter and cheese.

The discussion of the new law in the New York Legislature brought to light numerous facts concerning the manufacture of oleomargarine which are new and should be generally known. It was thought when the oleomargarine processes were first mooted, that the specially fine calf fat which the specifications called for would be obtainable in too small amount to allow the manufacture to reach very high figures. It has been shown that this safeguard against the large increase of the false product was purely imaginary, for while the specifications called for calf fat, the process really employed almost anything in the form of tallow, and, it has been claimed, went even farther and took in other animal fats. This being the case, it is apparent how the production has grown in New York State so that about one-fifth of the whole State make of butter has been oleomargarine butter during the year 1880, or in round numbers about 20,000,000 lbs.

This immense amount of false butter was made last year. The greater part of it no doubt went to Europe, and some turned up last fall in California, where fortunately there is a strong feeling against it, both among dealers and consumers. Too much reliance, however, must not be placed upon general sentiment in this matter, for the profit in handling oleomargarine is great, and some one will be tempted by it. As soon as this season's make of butter begins to shrink, and the price reaches 35c, or even 30c, perhaps, then watch must be kept out for oleomargarine. We shall certainly keep an eye upon it or in search for it.

The possibilities of future production of this substance in New York City alone are appalling. As we have said, almost any tallow seems to be available. The number of heaves slaughtered in New York average 10,000 per week, or 520,000 per annum. Averaging 100 lbs. of offal fats per head, from which 35 to 40 lbs. of the oleo is extracted, which, by the addition of such inexpensive articles as milk and salt, increases the manufactured product by about 25%, and it will appear that a fair average yield of butter is about 45 lbs. per head. Multiply this by 520,000 head and we have the enormous product of 23,400,000 lbs. Allowing that one-fifth of the slaughtered heaves in the State occur in New York city, we have four-fifths to add to the above product to represent the possibilities of the entire State production, making the enormous aggregate of 116,000,000 lbs. of oleomargarine butter. The entire State production of genuine dairy butter in 1875, according to the census of that year, including all made in families as well as factories, amounted to only 111,018,413 lbs. So that the possible annual production of oleomargarine butter in this State may exceed by nearly 5,000,000 lbs. the actual make of genuine dairy butter. The same line of computation, if carried to other States, will make the possibilities of oleomargarine butter alone, far exceed the 1,500,000,000 lbs. of natural production in the dairy sections alone. But oleomargarine butter may be produced as well outside of the dairy regions, thereby doubling or even perhaps quadrupling the above figures, when the whole country is taken into the computation.

The effect which the career of oleomargarine has already had upon the legitimate product, was also outlined in the earnest speech made before the New York law makers by those who befriended the true dairy industry. Testimony was cited to the effect that the dairy interest is already injured to the extent of one-third its value, or between \$50,000,000 to \$200,000,000. What is the extent of the imitation interests that are bringing upon us these evil results? It is only claimed that about \$15,000,000 is invested in this imitation manufacture, as against \$4,000,000,000 to \$6,000,000,000 invested in the production of the legitimate product, and there are perhaps a few hundred people interested in the adulteration as against the five to eight millions interested in the unadulterated product. And yet the situation, as has been shown, is such as to forbid the ruin of the natural by the imitation industry.

It was this view of the matter which carried the new law in New York State, and in nearly if not all of the dairy States of the country. It is plain that this untrue product must not be allowed to wear the guise of the genuine, but must be known by its own wretched name. This we have law for, and all produce dealers and consumers should act together to make the law effective. The issue may be expected in this State this fall: how shall it be met?

ANCIENT TIMBER.—The ancient temples of Egypt are supposed to contain the oldest timber in the world, in the shape of dowel pins, which are incorporated with stone work, known to be not less than 4,000 years old. These dowel pins are thought to have been made from the tamarisk or shittim wood, in ancient times a sacred tree in Egypt, and now occasionally found in the valley of the Nile.

### Ancient Copper Mines.

The mining of copper ore is attracting a great deal of attention, and the eyes of capitalists are turning toward Arizona and New Mexico. A very interesting article appears in the *Albuquerque (New Mexico) Journal*, in describing the copper mines known as Santa Rita del Cores, located five miles east of Fort Bayard. These mines were discovered by an officer in the Spanish army, in 1800, who, not possessing means to work them, sold them out entire to a wealthy Spanish gentleman, in 1804, who commenced working the property extensively. His first shipment of copper to Mexico proved a success. On account of the extraordinary quality of the metal he was enabled to make a contract with the royal mint for the purpose of coinage for the full annual product of the mines. The copper was transported to the city of Mexico, 1,000 miles on pack mules to Chihuahua, from thence by wagon. One hundred mules were continually employed, each mule carrying 300 lbs. The force employed in working consisted of 390 men. It is claimed that the last year the mine was worked the proprietors cleared the net sum of \$500,000, and that the gold found in the copper paid all expenses. Notwithstanding a good title is vested in these mines, they have several times been jumped by prospectors. While the Santa Ritas are by very many considered the richest deposits of red oxide of copper known, they are strictly the most peculiar and really singular copper mines in the world. They are not veins or lodes; but on sinking a shaft, the miner continually meets with veins of native sheet copper from  $\frac{1}{2}$  of an inch to two inches thick all through the country or porphyry rock. He often meets with howler or nugget copper, in nuggets weighing from 50 lbs. to 150 lbs. These lumps are, on account of their peculiar formation, called by the miners kidney lumps. These mines, according to account, are inexhaustible, and bid fair to become more famous in the present day than they were in the past.

### The Miner as a Civilizer.

The following appreciative sketch is from the *Southern Utah Times*:

Much fault is often found with the miner, and perhaps not always without reason. But with all his faults he has one side to his history that all are forced to recognize, that is, that he is the harbinger of civilization. From the opening of spring to the close of summer, he is in constant migration, roaming from gulch to gulch and mountain to mountain in search of precious metals. Untiring of his peculiar industry, summer after summer he continues to penetrate the trackless regions of all countries in which metals of intrinsic value are found. He scales the loftiest peak in search of metal-bearing veins, and explores the lowest gulches in search of placer gold mines.

He fords and swims rivers that none but the bravest would encounter, often at the risk of his life. He is usually strong in body and of the most determined will. He is austere in manner, but has a generous, kind heart, and as a rule, he is the manliest of rough men. He is a sturdy, unpolished man, combining skill, judgment and courage in a degree sufficient to propel him through any journey he may undertake. If he succeeds in finding a mine that will justify him to remain and operate it, he is sure to stay, and every inhabitant of that certain section must leave or bend in obedience to his will.

His trail is followed by the farmer, the ranchman, the teamster, until every acre of arable land in the locality is reclaimed, and good roads to the El Dorado are made. Then follows the more polished and more solid elements of society, and the wilderness is in this way brought under cultivation, and enlightenment spreads and penetrates the remote interior of all countries through the efforts of the *prospecting miner*. The wealth of all countries is stimulated by his discoveries, and the foundation of new States laid. Therefore, the development of the immense area of the mineral regions—nearly one-third of the nation's domain—must be recognized as an important factor in the development of political institutions, and to the explorer of metals is due the beginning.

Left to all other sources and influences, the "valleys in the mountains" would for centuries remain homes for the savage and the wild beasts. For without the discovery of mines in the surrounding mountains, no market could be found for the products which would make limited fertile valleys profitable to an agricultural community. The political importance of the explorer for precious metals is well worthy of close study and attention. The other side of his life, however, will show that he is not a close student, and his demands are consequently at times extraordinary.

CURIOUS PROPERTIES OF MAGNETIC IRON.—A curious magnetic property of the meteoric iron of Santa Catarina (Brazil), has been lately observed by Prof. Lawrence Smith, of Louisville. Small detached fragments, not weighing more than 0.1 to 0.5 gr., were very weakly affected by a magnet; but on being flattened on a piece of steel with a steel hammer, they became very sensitive to it. By heating red hot, the particles were made to be still more easily attracted than by flattening. The meteoric iron in question contains 66 iron, 34 nickel.

## THE ENGINEER.

## Brick Foundations.

Trautwine, who has experimented considerably with building materials, says on this point that a rather soft brick will crush under a weight of from 450 to 500 lbs. per square inch, or about 30 to 40 tons per square ft., while a first-rate machine-pressed brick will require from 300 to 400 tons per square ft. This last is about the crushing limit of the best sandstone—two-thirds as much as the best granites or roofing slates. But the masses of brickwork he notes, will crush under smaller loads than the single bricks. In some English experiments, referred to by this author, small cubical masses only nine inches on each edge, laid in cement, only two days after being built, required 44 to 62 tons per square ft. to crush them. Another, of pressed brick, in best Portland cement, is said to have withstood 202 tons per square ft., and with common lime mortar only one-fourth as much.

The same authority, however, is careful to add the statement that cracking and splitting usually commences under about one-half the crushing loads. To be safe, he recommends that the load should not exceed one-eighth or one-tenth of the crushing load; and so also with stone. Moreover, he notes, these experiments were made with low masses, but the strength decreases as the proportion of the height to thickness increases. He cites the following examples: The pressure on the base of a brick shot tower in Baltimore, 246 ft. high, is estimated at 63 tons per square ft., and in a brick chimney at Glasgow, Scotland, 468 ft. high, at 9 tons. Prof. Rankin calculates that in heavy gales this pressure is increased to 15 tons on the leeward side. The walls of both are, of course, much thicker at the bottom than at the top. With walls 100 ft. high, of uniform thickness, the pressure at the base would be 5.4-10ths tons per square ft. He prudently concludes that with our present imperfect knowledge on this subject it cannot be considered safe to expose even first-class pressed brickwork, in cement, to more than 12 or 15 tons per square ft., and good hand-molded bricks to more than two-thirds as much.

**TO SECURE GOOD COMBUSTION.**—1. The gas must be thoroughly burned. This can be secured only by burning it with hot air and in a red-hot chamber. Therefore the air for burning the gas must be heated in some way before it enters the boiler furnace, and there should be a hot fire-brick combustion chamber separate from the boiler, so that its temperature may not be reduced by contiguity of the comparatively cold surface of the plates of the boiler. 2. The temperature in the boiler furnace must be the highest possible attainable by the combustion of the waste gases. This requires not only complete combustion, but the absence of an excess of air. 3. The heat produced by this combustion should all be absorbed by the water in the boiler, except barely a sufficient amount to heat the escaping gases to the temperature required for draught. These conditions are exactly those required for the best results in boilers heated by solid fuel, but we think they are entirely overlooked at many furnaces. We have seen the draught stack of a nest of steam boilers red hot at night and a long column of flames steadily emerging from the top. The furnace at which this took place was using about two tons of fuel (coke) to the ton of iron.—*American Engineer.*

**MEAN VELOCITY IN OPEN WATER COURSES.**—The discharge of open water courses may be found experimentally by observing the velocity of the current, and measuring the cross-sectional area of the stream. But to do this correctly, we require the mean velocity throughout the section, which cannot be obtained by observation. The velocity varies, being a maximum at the surface, and where the channel is deepest, which is usually near the center of the width, diminishing from thence to the banks on either side and to the bottom, where it is a minimum. The best experiments we have, give the mean velocity throughout the section at 84% of the maximum central surface velocity, which is usually the velocity observed, being easily obtained by a float on the surface of the stream. Thus, if a channel has, by observation, a central surface velocity of 35 ft. per minute, the mean velocity will be 29.4 ft.

**TUNNELING MONT BLANC.**—The project of tunneling Mont Blanc bids fair to assume a tangible shape, it being pronounced by some of the most eminent French engineers a more practicable undertaking than that of the Simplon route. The estimates of cost for executing such a work are, in the case of the Simplon, \$27,000,000, and in that of Mont Blanc some \$12,000,000 less. It is further claimed that the Mont Blanc tunnel will make the journey from Paris to Genoa some 97 kilometers shorter, and from Paris to Milan 44 kilometers shorter than by the Simplon route. The most favored line of the projected tunnel thus far in the discussion, is from Chamounix to Courmayeur.

**SOLAR HEAT.**—M. Pifre, a French engineer, has so far improved on the apparatus invented by M. Mouchot, for using the solar heat-rays for practical purposes, that he states he obtains 80% of the available sun's heat in Paris, which is equivalent to a gain of 30% in efficiency.

## USEFUL INFORMATION.

## Luminous Paint.

## Its Philosophy and Practical Application.

It appears that luminous paint is gradually working its way into practical use. Dr. Morton, of New York, recently delivered a lecture upon the subject, in that city, which is reported in the *New York World* as follows:

The lecture was accompanied by some curious experiments with sulphide of calcium paint. Dr. Morton said that while heat, to become luminous, must be made very intense, phosphorus emits light with very little heat. Phosphorescence is a purely chemical action, but there is a class of phosphorescents that do not depend on chemical action. The means of producing light are both mechanical and chemical. Thus, the blacksmith, as he strikes the iron, produces first the long bent waves, the vibrations growing gradually shorter until a white heat results. But the long waves continue to vibrate at the same time with the shorter light ripples. With phosphors, the higher wavelets can be produced without beginning with the long waves. Sulphate of quinino and other substances have the power of taking short rays while they emit longer waves. They do not store up the light, but emit it in 1-500th part of a second. Phosphorescent bodies do not act in so short spaces, but emit a somewhat larger wave. Bodies have been manufactured which will continue the emission for a very long time. When light falls on phosphorescent bodies, it effects a molecular change and thus stores up energy. When the light is emitted, the molecules fall back into their natural place and develop energy also. In the case of sulphide of calcium heat is the agent that develops this energy. It is made by heating sulphur and lime together. It has been so improved in manufacture that it now emits light for hours.

Dr. Morton then exhibited a plate of glass painted over with sulphide of calcium, the hall being darkened for the purpose. It gave a very clear, bluish light. He said that a window thus coated would light up a room during the night, while it would be transparent during the day. A painted lantern was shown which could be taken around without any need to recur to matches. A star cut out of pasteboard on a canvas coated with the paint appeared perfectly black, while the canvas gave forth the peculiar bluish-white light. A tin globe painted with the sulphide, and magical sign-boards which gave out the letters on them or exposed a dazzling white surface, according as the room was darkened or not, excited the admiration of the audience. A bust, the hair and toga of which were painted, while the face and breast were not, was very pretty, the face and breast, being yellow, gradually getting darker, while the robe was a dazzling white. Dr. Morton said he could make his way easily through a dark cellar by its aid. There is, of course, no danger of fire. He said he looked forward to the time when the use of the sulphide of calcium would obviate a great many dangers to which miners and others are exposed.

## Luminous Paint in England.

An English journal, *Design and Work*, gives the following account of some interesting demonstrations of the practical uses to which this paint may be applied. We quote as follows: Messrs. Illies & Horne, of London, sent us an invitation to see their luminous room, which we accepted. This room, in the ordinary state, is perfectly dark. The ceiling, however, has been painted with three coats of Balmains' luminous paint, which, when exposed to the ordinary light of day, collects and retains a surprising amount of light.

Upon entering into this room the appearance is that of a pale moonlight, in which the various objects were distinctly visible. It was very difficult at first to persuade one's self that the light was merely emanating from the ceiling, and that it was not due to some leakage of light from outside. This was, however, tested by failing to observe any shadow, which would have been shown had the light made its way from without. Around the room, hung upon its wall, and standing upon a large table in its center, were various objects which one has, more or less to look for in the dark. Among these was a life buoy, which shed a halo of peculiar violet white light, a clock dial showing the hands and figures very plainly, a luminous match box, a statuette, all of which, with many others, had received a coating of this extraordinary compound.

The words "Caution," "Beware of the Dog," "Lodgings," "Mind the Hatchway," and several other sentences appeared with marvelous distinctness, having been painted with the luminous compound.

Just outside the luminous room was another from which all light was excluded, but not painted with anything save the ordinary paint and whitewash, so that there was nothing visible in the blackness. Into this room was brought a large frame square of glass, the back of which had received several coats of luminous paint, which rendered the room luminous to see what was going on, to tell the time by a watch, the names of books on the book-shelf, and other details too numerous to mention.

The paint is of a whitish cream color, and is made in two ways—as a water paint, or white-wash for ceilings, walls, etc., and as an ordinary stone color oil paint, for use in the ordinary way.

## AN IMPORTANT INVENTION—COATING TIN.

**PLATES WITH GLASS.**—The great danger of suffering from the effects of certain chemical actions taking place between the acids and salts in the substances packed in cans and the tin in the plates from which cans are made, will soon be removed, if the following described invention can be made practicable. It is stated in an English paper that a firm at Dunstable provides receptacles made of plates faced with a material which interposes a film between the surface of the metal and the fruit or other contents. The insoluble portion of this composition is silicate of lime or fluo-silicate of lime (glass-powder), previously acted on by fluoric acid; the soluble portion being silicate of soda and potash. Preferably that kind of silicate of lime is used which has been procured by double decomposition from polysulphide of calcium, chloride of calcium and hydrate of lime; or there may be used a silicate of the earthy bases or metals, or precipitated gelatinous silica. The alkali may be fixed or removed by a both containing a dilute solution of fluo-silicic acid, when fluoric acid has not been used, or a dilute solution of any other suitable acid. To make the composition mix the soluble with the insoluble silicate in equal proportions, although these may be varied according to the consistency required. The plates are coated with the mixture by a brush or by dipping into a bath. After coating, the plates are dried by heat, and are ready for manufacture. This invention furnishes a plate with a surface somewhat resembling glass, but without the aid of fusion; and this coating cannot be separated from the metal, which may be bent or worked in any manner desired.

**MEASURING BUILDING MATERIAL.**—The following figures are worth remembering, as they will save a great deal of calculation and give approximately accurate results with a minimum of labor: A cord of stone, three bushels of lime and a cubic yard of sand will lay 100 cu. ft. of wall. Five courses of brick will lay one ft. in height in a chimney. Nine bricks in a course will make a flue 8 in. wide and 20 in. long, and eight bricks in a course will make a flue 8 in. wide and 16 in. long. Eight bush. of good lime 16 bush. of sand and one bush. of hair will make enough mortar to plaster 100 sq. yds. One-fifth more siding and flooring is needed than the number of square feet of surface to be covered, because of the lap in the siding, and matching of the floor. One thousand lathes will cover 70 yds. of surface, and 11 lbs. of lath nails will nail them on. One thousand shingles laid four in. to the weather, will cover over 100 sq. ft. of surface, and five lbs. of shingle nails will fasten them on.

## GOOD HEALTH.

## The Uses and Abuses of Glucose.

Dr. Kedzie, President of the Michigan State Board of Health, contributes to the *Bulletin* of the National Board of Health a valuable paper on the adulteration of food, in the course of which he exposes the practice of substituting glucose, the sugar of the grape, or that made from starch, for cane sugar, which has two or three times the sweetening power of glucose. One gallon of syrup made from sugar cane, he writes, has more sweetening than four gallons of glucose syrup. If glucose syrup sells for 100 cents a gallon, glucose should sell for 24 cents to represent the money cost by an equivalent value in sweetness. The comparative cheapness of glucose naturally induces the suspicion that it is largely used to adulterate cane sugars, but he has not found such to be the case.

Grape sugar does not crystallize readily, nor in forms identical with the sharp, clearly defined crystals of cane sugar. "I have analyzed a large number of 'granulated,' 'crushed' and 'powdered' sugars without finding glucose in a single instance." In brown coffee sugars, however, he has detected glucose, but not in heavy proportion. In the common candies, where the crystalline form is avoided purposely, glucose is often used in large quantities. In the table syrups—sugar-house, golden and silver "drips," rock candy drips, etc.—the substitution of starch for cane sugar is very general. The average proportion of glucose in nine specimens of these commercial forms of molasses was about 90%. An outrageous use of glucose syrup is that of feeding bees upon it in order to increase the yield of "honey." Not only is extracted honey largely adulterated with glucose syrup, but the honey in the comb frequently consists of little else than syrup of glucose.

Bees gather honey from flowers, but do not make it. If we feed them on starch or cane sugar, excluding other food, they will simply fill their combs with syrup, not honey. This substitution of starch sugar in place of honey is a shameless fraud, and imperils an important industry—bee farming. A very promising foreign demand for honey will soon stop unless this fraud is prevented. Congress ought to pass a law to protect the bee-keepers and the honey-eaters. It may not have power to prevent persons feeding glucose to their bees, but it can compel them to label their honey for just what it is, or send them to prison for obtaining money under false pretenses, if they sell such stuff for honey.

## Lungs Filled with Iron.

A singular post-mortem discovery was recently made at Fulton, N. Y., in the case of a long suffering machinist. The case was that of Joseph Bausel, whose post-mortem examination, according to the *New York Sun*, developed a phenomenon which surprised the doctors, and has been the theme of considerable medical speculation. Bausel, who was 48 years old, was a native of Wales, and in boyhood was apprenticed to the trade of machinist and loom-fixer, which he followed in various factories in Wales and England before he came to this country 13 years ago to set up the machinery in the Oswego Falls factories, opposite this place, on the Oswego river. The machinery was of English invention, and required an expert to adjust it. Bausel was an excellent workman, and was given constant employment here at his trade, which involved the adjusting of machinery by filing the joints to make them fit smoothly. He had an extraordinary amount of this work to do, for the reason that the managers of the Oswego Falls factories here have constantly been putting in new machinery, and extending their mills.

At the post-mortem examination, it was observed that the upper surfaces of the lungs had a strangely mottled appearance. On closer examination it was found that it was covered with iron or steel filings, embedded in the tissue. On the under side of the lungs there was no trace of filings. A quantity of dark-colored blood was found in the stomach, the mucous membrane of which was engorged, and the heart was greatly enlarged with ossifications as large as the end of the thumb, on the mitral valve.

When the metal filings on the lungs were discovered, one of the physicians remarked that they showed clearly what the man's occupation had been. The doctors say that other persons similarly engaged are likely to become similarly affected by inhaling steel and iron filings, and that the deposit on the lungs might, and probably would, be fatal, especially if the pulmonary organs were not strong, or the man exceptionally robust. Paralysis and enlargement of the heart complicated the case of Bausel, and resulted in his death. The examination was not carried far enough to determine the amount of the metal filings embedded in the lungs.

**PHYSIOLOGICAL ACTION OF SALTS OF GOLD AND OTHER METALS.**—A very remarkable series of observations has been made by Dr. James Blake, concerning the physiological action resulting from solutions of different salts when introduced into the blood of living animals. He finds that salts of the same isomorphous group produce an intensity of physiological action in proportion to their atomic weights. For instance, the salts of thorium, palladium, platinum, osmium and gold showed great similarity in their physiological action, all of them having a decided and characteristic effect on the heart. The action of gold compounds was surprising; in minute doses of 0.003 gramme per kilo, it kept up the action of the heart for several hours after death, though the temperature of the body had fallen 13° below the normal heat.

**SPANKING AND FLOGGING AS THERAPEUTIC MEASURES.**—A year or two ago Dr. I. E. Taylor showed the excellent effects to be derived from spanking the child and flogging the mother (with a wet towel), in some of the accidents of parturition. Dr. Heurot, of Paris, has found the same measure admirable as a remedy in hysterical spasms. We recollect that, as a small boy, we took some doses of this same preparation for certain emotional diseases, such as slight kleptomania (toward apples), acute ira, and disorder of the organs of speech (prophasia); in these and similar disorders, we join in giving our fullest recommendation.—*Phila. Med. and Surg. Reporter.*

**ON THE CAUSES OF LEPROSY.**—Dr. Jonathan Hutchinson, in the *Press and Circular*, says: "We find that nearly everywhere the disease is most common on the seashore, and that when it spreads inland it generally occurs on the shores of lakes, or along the course of large rivers; we find also that fish is largely eaten where leprosy prevails. I don't believe that any other article of diet has any influence whatever on the causation of the disease; this is so special in its character that it must have one special cause."

**NEW REMEDY FOR PARASITES.**—Physicians are often troubled to give relief to the symptom of itching which so frequently forms a prominent feature in certain skin diseases, and the most varied local measures are often used with the result of aggravating the local irritation. The list of internal remedies used for allaying this distressing condition is a limited one, and from it chloral and bromide of potassium stand out almost alone; but the objections to the continued use of these are too obvious to require mention.

**KISSING IN DIPHTHERIA.**—The late Princess Alice, oldest daughter of Queen Victoria, and wife of an Austrian prince, lost her life a year or two ago through a kiss. Two of her children died of diphtheria, and she could not resist the entreaties of her dying boy to "kiss mamma;" she kissed his paling lips in an agony of motherly love, and took the dread disease, which resulted fatally.

## TABLE OF CONTENTS.

EDITORIALS.—Foundry Notes; Sinkin Pump; Safety Attachment for Mine Cages, 421. Passing Events; Close of the Volume; Caution and Counsel to California Miners; Notes on Roscoelite; The Coming Fair, 428. The Great South Dome, Yosemite Valley, 429. Patents and Inventions; Notices of Recent Patents, 432.

ILLUSTRATIONS.—New Sinkin Pump for Mining Purposes, 421. Climbing the South Dome, Yosemite; Anderson's Cabin, Back of South Dome, Yosemite Valley, 429.

CORRESPONDENCE.—Wood River Mines; Volatilization of Gold; Experiments in Chlorination, 422. MECHANICAL PROGRESS.—Aomalous Action of Leather Belts; American Mill Machinery in Europe; The Hammer; Sand in Welding; Steel, 423.

SCIENTIFIC PROGRESS.—Storage of Electricity; New and Curious Properties of Metallic Salts; Gzom; Does Iron Expand on Passing from a Liquid to a Solid? 423.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Assessments, Meetings and Dividends, 424.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Montana and Oregon, 424-5.

MISCELLANEOUS.—Reduction Facilities; Industrial Progress, 422. The Hydraulic Miners' Meeting; Production of Arizona; Grid-Ironed; The Glamorganshire Wrong; Ancient Copper Mines; The Miner as a Civilizer, 426.

THE ENGINEER.—Brick Foundations; To Secure Good Combustion; Mean Velocity in Open Water Courses; Tunneling Mt. Blanc, 427.

USEFUL INFORMATION.—Luminous Paint; An Important Invention—Coating Tin Plates with Glass; Measuring Building Material, 427.

GOOD HEALTH.—The Uses and Abuses of Glucose; Lungs Filled with Iron; Physiological Action of Salts of Gold and Other Metals, 427.

NEWS IN BRIEF on page 432 and other pages.

## Business Announcements.

Callistoga Hot Springs—A. C. Tichenor, Proprietor.  
 Turbine Pumps—San Francisco Tool Co., S. F.  
 Assessment Notice—Steeple Hollow G. M. Co.

## Passing Events.

Since the last issue of the PRESS the hydraulic miners have held a meeting and expressed their opinion on the debris question in a series of resolutions, which we publish in another column. A fire entailing a loss of \$250,000 has occurred at Tombstone, Arizona, mainly in the business portion of the town. Most of the dwellings and a good many of the business houses were either adobe or built of board and canvas—balloon frames—and, of course, burned rapidly. Our copious mining summary will give a good idea of the situation in the various mining localities.

We close volume XLII this week, and it is just as well to bear in mind that this is a good time to renew subscriptions, and for new subscribers to end in their names.

The week has seen the culmination of the grand celestial phenomena which have given timid people occasion for much ecstatic worrying. On Sunday morning many persons went to church with the fear that some exquisite cataclysm might occur before they returned to their homes. They were doomed to disappointment for the appointed hour for the conjunction of the great planets came and went, and the little earth wiggled along through space, apparently unmindful of the peculiar position into which the other members of the planetary family had come.

BEAUTIFUL LEAVES.—Let the tourist in California mountains, during a bright May or June day, lounge upon Mother Earth's back (and his own back) under a newly-leaved oak and observe the leaves which happen to come singly between his vision and the sun. They will appear as if made of transparent wax, with delicate veins and velvet edges tipped with shining silver.

## Close of the Volume.

With this number is concluded Volume XLII of the MINING AND SCIENTIFIC PRESS, and the paper may, therefore, be said to have attained its majority, this being its 21st birthday. Twenty-one years is a very long time anywhere, but especially in the life of a Pacific coast newspaper. The PRESS may consider itself one of the firmly fixed features of California, and is a pioneer in every sense of the word. Especially does it pride itself in being the pioneer of the mining journals of the country, in view of the fact that there are now so many of them, and that the mining industry has come to the front as one of the leading industries of the nation.

We may be supposed, after so many years, to have acquired some experience in the management of a mining journal, since this paper has, with the exception of the first year, been under the management of the same proprietors during all these years. For ten years past its editors have been the same. We see the same mistakes in mining matters repeated by the new comers, and take occasion repeatedly to warn them of the pitfalls which lie in their way, and which our experience points out. If this advice is not heeded it is no fault of ours.

We have aimed, with the advance of years, to have the PRESS show a material advancement, and we think we have done so. The index, on the last page of this number, will show the scope of the contents of the paper for the past six months. It will speak for us more plainly than anything else.

It is customary on such occasions as this to remind our readers that this is a good time to subscribe, but as we have followed this custom many years, we will not do it this time for a change.

## Caution and Counsel to the California Miner.

Excited by the speciose allurements of Arizona, Wood River, and other outside districts, there is danger just now that many California miners be enticed to pull up stakes and leave the State for what may seem to them more promising localities. That some may improve their prospects and, perhaps, finally their fortunes, by emigrating to these new fields of enterprise, we are not disposed to question. Whether this be or not, certain it is that to the veteran prospector, and that class of restless wanderers that follow close in his wake, it would be useless to address words of either caution or advice. To remain where they are, and settle down to steady hard work, making the most of their opportunities and surroundings, is a thing no one expects them to do. The disposition to roll up their blankets and strike out for the site of the last new thing in the way of a mining excitement, has with them become chronic and incurable—a sort of second nature, that must stay with them to the end.

That the gratification of this passion has kept the most of these men poor; that it has rendered them homeless and homeless, converted them into waifs drifting on the tide of events, buffeted by every wind of chance, signifies not. The "Wandering Jew" was not more fated to continue his endless journeyings than are these nomads to get up and skurry away when first the rumor of mineral discoveries made afar off reaches their ears. Consigning to their destiny these irreclaimable tramps, let us address a few words of counsel to that class of miners who have not yet fallen into this roving habit, or with whom it has not, at least, become fixed and irrepressible.

In the first place, then, when tempted to leave California for any of these remote and much bewitched discoveries let the staid and thoughtful miner consider how, almost always, the importance of these reputed new finds is grossly, not to say shamefully exaggerated, the story of their extent and richness arising often from misapprehension and ignorance, or being the villainous fabrication of interested parties. Never have the first reports of these discoveries been subsequently verified, the most of them, as is quite notorious, having had no foundation whatever in fact. In so far as any benefit ever accrued to the masses who left California for Frazier river, Washoe, or any other localities outside her borders, every one of these movements may be pronounced dead failures, not one man in a hundred of those who were carried away by these excitement but would have been better off had he remained where he was. Let the miner who contemplates a journey to any of these outside places ponder well this significant fact.

Then there arises to the man who remains and pursues his calling in a neighborhood where he is acquainted, this advantage; he not only saves his time and money, but he is pretty sure to earn something. Making available his knowledge of the diggings, he can hardly fail to earn enough to pay his way and a little more. This the stamper does not always do; on the contrary, he is apt to spend what he had and return to his old home "dead broke." Seventy per cent. of his kind come back from their campaigns in a worse plight than the Prodigal Son—out their expenses and incontinent "strapped." In this we have another phase of the question for a prudent man to ponder.

Again, California is a pleasant, healthful con-

try for a man to live in. Even if he does not make so much money, he can enjoy life here and otherwise get a great deal more out of it than is possible in these sage brush, alkali lands with their cloud-bursts, sand-storms; and their siroccos, their brigands and blizzards. As regards health, this State is a vast sanitarium, in which men, but for their bad habits or inherited disease, would live until old age. Bare existence amounts to something in a country and a climate like this. Better live here, under the wide-spreading boughs of an umbrageous oak, than in a palace almost anywhere else. And are not the mining regions the most desirable places of abode in all this broad and delectable land? Is there another such place for the homes of white men as these foothills of the Sierra, with their salubrious atmosphere, their magnificent rivers, stately forests, rich, red soil and their gold? Not another in all the world. Go where you will—traverse the face of the earth over and you will not find it like.

And let the California miner think of this, too, and stopping where he is, let him take up some land, inclose, plant and cultivate it, and make there a home. While doing this, it will be an easy matter to secure also some mining interests near by. And, certainly, these are things to be looked after. If not very valuable now, they will be by-and-by. Quartz veins that possess no value to-day will, with the improvements that are being made, be worth a good deal in the course of a few years. Our advice to miners, therefore, is that they take up these properties and hold on to them. A gold mine will, after a while, be a handy thing to have on the premises.

Nor are the remnants of the placer diggings thing to be despised. There will come for them, too, a day of regeneration—not swift, but slow and sure. There is much gold to be gathered yet in the California placers; and, with the new aids to be introduced, it will be done with such profit as will encourage thousands to again engage in the business. Many of the old bars and gulches will be gone over once more; the tailings that encumber the canyons and streams will be reworked; the river beds will be drained and worked—possibly dredged out, notwithstanding the failure that have thus far attended trials with machines of this kind. The low grade gravel banks will be hydraulized or otherwise disposed of, and the deep-lying channels of the ancient rivers will be opened up and drifted out. While some portions of this forward movement will be deferred, much of it will be the work of the early future.

To the waiters and toilers in our own mines, we would say, then, stop in California; abide where you are; take up mines and stay by them; get land; own, beautify and plant it. This will be better than a pilgrimage to Tombstone, Yankee Fork or Wood River, even if you could be assured that it would be attended with much more than the average success.

## Notes on Roscoelite.

[Written for the PRESS by HENRY G. HANES, State Mineralogist.]

Roscoelite is a new and extremely rare mineral found in El Dorado county, California.

Attention was first called to it by the reading of a paper by Dr. James Blake, at a meeting of the San Francisco Microscopic Society, July 2, 1874. The specimen then exhibited were from a mine or claim, known as the "Stuck-slayer," "Plum Tree," or "Sam Simms" mine, which lies in section 24, township 11 north, and range 9 east, Mount Diablo base and meridian; somewhat more than a mile from the town of Coloma, in a southwest direction.

At a meeting of the California Academy of Sciences, held on July 20, 1874, Dr. Blake presented specimens of the same mineral, which he then supposed to be a chromium mica, having in a preliminary examination found, as he supposed, chromic acid combined with silica, potash and lithium. Gold was also associated with the mineral in considerable quantities. He stated that it was found at Granite creek, near Coloma, El Dorado county, remarking at the same time that the associated minerals were an interesting and beautiful microscopic study, and that the formation indicated that the gold must have been deposited between the flakes of the mica from an aqueous solution. He gave the new mineral the provisional name of "Colomite," from the locality.

The next notice appears in the proceedings of the California Academy of Sciences, Vol. 6, 1875, folio 150. At a meeting held August 2d of that year, Dr. Blake read a paper on "Roscoelite"—a new mineral, in which he admitted that he had stated at a former meeting that the mineral contained a large quantity of chromic acid, an opinion derived from the results of superficial blow-pipe tests. He had since sent samples to Dr. Genth, of Philadelphia, who found it to contain vanadium. He had given the name Roscoelite as a compliment to Prof. Roscoe, of Manchester, England, who has made vanadium a special study. In a foot-note, Dr. Blake expresses the opinion that vanadium may occur in these rocks in larger quantities than is generally supposed; and calls attention to the fact that Dr. Hall has found it widely diffused in many rocks.

The vein from which the Roscoelite was taken is small and not continuous, varying from two inches to a foot in thickness, running nearly parallel with Granite creek.

The quartz is ferruginous in appearance, and is associated with calcite and slaty matter, and

at least two varieties of pyrites. Gold only occurs with the Roscoelite, and usually in parts of the vein where the quartz disappears, or "pinches out," as the miners express it.

Roscoelite was for a long time a mystery to the miners and was at first mistaken for plumbago. The pioneer placer miners on "Big Red Ravine" used to complain of the difficulty of saving the gold, owing to the interferences of the "black stuff," as they designated it. In all probability a large quantity of gold was allowed to escape from ignorance of the nature of this mineral.

Gold is found interstratified with lamina of Roscoelite, or imbedded in it, in pieces from the value of one dollar, to the minutest microscopic particles.

The method of operation at the mine has been to remove superficial slaty covering by ground sluicing, and carefully working the small but exceedingly rich material found in this pay-seam. From one pan of this, 40 ozs. of gold has been taken; from another, good to the value of \$100 was obtained. The fineness of the gold is 846.

Under the microscope Roscoelite is seen to be in scales and radiated tufts, the luster of which is silvery or pearly to a high degree—almost metallic by strong reflected light; color, light steel gray, yellowish dark green, or nearly black, as seen in different lights. Small deeply striated crystals of white iron pyrites are sometimes seen on freshly broken surfaces of quartz, partly imbedded. The quartz in actual contact with Roscoelite is generally transparent and nearly colorless; sometimes rose colored or amethystine. Although rather common in the ores, pyrites has not been observed in contact with Roscoelite.

When magnified 70 diameters, Roscoelite resembles the variety of pyrophyllite found at Greaser gulch, Mariposa county. As far as observed the associated gold is always bright, of good color and amorphous, generally rounded as if water worn.

The other mineral associates of Roscoelite are calcite, and a yellow mineral, which is probably marcasite or chalcophyllite, found only in microscopic quantities.

The only other known locality of Roscoelite in the State, is section 31, township 11 north, and range 10 east, two miles from the Sam Simms mine. Big Red Ravine is on this section, lying only two miles from the site of Sutter's mill, where gold was first discovered. It was one of the earliest placer mines known in the State, and so rich did it prove, that it has paid to re-work as many as seven times. It is in the bedrock of these old workings that Roscoelite is found.

I am indebted to Mr. George W. Kimble, surveyor of El Dorado county, for valuable information and for specimens of this rare and interesting mineral—with him I walked over the ground while he pointed out the localities—the largest mass found here was taken out by a Chinaman and is described as having been as large as a gallon measure. From first to last 400 to 500 lbs. of Roscoelite have been obtained all of which was wasted in extracting the gold.

I was only able to obtain for the State Museum a thin piece of quartz of a few inches superficial surface, coated on both sides with Roscoelite; some large masses showing the mineral in spots, and some beautiful microscopical specimens containing gold.

At the Red Ravine locality, Roscoelite is found in a dark colored bluish micaceous rock in small seams of quartz and calcite with gold. This rock has not yet been studied.

Through the politeness of Mr. James Taylor, of Owen's College, Manchester, Eng., I have been furnished with the following analyses of Roscoelite:

Analysis of Roscoelite by Prof. H. E. Roscoe, of Owen's College, Manchester, Eng.:

Silica.....	41.25
Vanadic Acid (V, 2; G, 5).....	23.80
Alumina.....	12.84
Sesquioxide of Iron.....	1.13
Oxide of Manganese (Mn, 3; O, 4).....	1.10
Lime.....	.61
Magnesia.....	2.61
Potash.....	3.56
Soda.....	2.01
Water combined.....	1.08
Moisture.....	2.27

Total.....100.27

Analysis of Roscoelite by F. A. Genth, of the Laboratory of the University of Pennsylvania:

Silica.....	47.69
Oxide of Vanadium (V, 6; O, 11).....	22.03
Alumina.....	14.10
Peroxide of Iron.....	1.67
Magnesia.....	2.00
Potash.....	7.59
Soda.....	.13
Insoluble Silica, Quartz and Gold.....	.83
Loss on Ignition.....	4.96
Lime and Lithium, Traces.....	—

Total.....101.02

OTTAWA, Ont., experienced a slight shock of earthquake recently, causing considerable terror.

SERIOUS trouble exists between the Mexican States of Durango and Coahuila, and the former has been invaded by an armed body of men.

ANDREA LA CHAPPELLE died at Portland, Or., recently aged 100 years, having resided on the coast since 1817.

COL. ROBERT G. INGERSOLL is said to have become a millionaire through investments in New Mexico mines.

## The Great South Dome, Yosemite Valley.

(Written by G. H. S.)

In 1874, Prof. Whitney wrote as follows: "The Half or South Dome is a crest of granite rising to the height of 5,000 ft. above the valley, seeming perfectly inaccessible, and being the only one of all the prominent points about the Yosemite which never has been and perhaps never will be trodden by human foot."

A close examination of this elevation shows that the prophecy would appear to be warranted. The valley front is a smooth, nearly vertical flat wall, which gives the name Half Dome. The remainder approaches an oval dome shape, falling off rapidly from the top to 60°, 70°, 80°, and nearly vertical as it goes down toward the valley, and these sides are from 2,000 to 4,000 ft. high, except at the rear side, nearly opposite the flat front face. On this side it is approached to within about 2,000 ft. by a comparatively easy trail, which diverges some distance above the Nevada fall, from the trail to Cloud's Rest. Upon leaving the woods, the Dome becomes visible for the first time. The first elevation is called "The Saddle." It is a steep narrow ridge, sloping down rapidly to each side, and is very steep upon the ridge itself, but there are many large rocks, some crevices, and an occasional scrubby pine bush by which to hold on until this ascent has been overcome.

Then comes a depression, or saddle, between its highest point and the dome, and this also slopes off, as its name indicates, so as to leave but a narrow standing room in the center. From this point the curved slope of the dome commences, and extends 900 ft. to the top. The actual angle is from 38° to 40°, and in some places possibly a little greater, which does not seem very steep when laid out on paper, but when it is in the form of a smooth granite rock, and has, in addition, a slope upon each side, it is had enough to look up to, and is extremely trying to the nerves to look down at, unless they are pretty steady. The layers of rocks on the sides are in the form of shells, overlapping downward like shingles; whenever there are any breaks, these form steps of from one to two ft. high, which must also be surmounted while ascending the incline. This defeated all attempts which were ever made to climb this rock, until October, 1875, when Mr. Geo. G. Anderson succeeded, after two days and a half, in accomplishing the ascent. Mr. Anderson is a Scotchman, who has resided in the valley for 15 years. He is a ship carpenter by trade, and had followed the sea in that business for many years before settling on shore. Before his residence in the valley, he was engaged in putting up one or two suspension bridges over the Tuolumne and other rivers, and acquired considerable local fame for fearlessness and steadiness of nerve. After determining to try the ascent of the dome, he prepared eye-bolts, drills, chisels, and the necessary ropes, and packed them to a convenient place, and after much hard work he reached the top, and planted a flagstaff there. Since that time quite a number of men, and some ladies have climbed the dome, and have been repaid for the risk by the grandest view in the valley.

Last year the rope became unsafe, and was out to prevent any further attempts and possible accidents. All this excited my interest, and when Anderson offered to accompany me to the Saddle, which he said was as far as we could go, I eagerly accepted the invitation, and this morning, accompanied by a friend, we started at seven o'clock, passing the Vernal Fall, and climbing the steep, narrow trail which surmounts the Nevada Fall, we followed a comparatively easy path toward Cloud's Rest, until we reached a point where we turned off and commenced the ascent toward the Dome. All of this portion of the trail leads through the forest, crossing little streams and some rocks, until we pass the oahin where Anderson lived and prepared the iron work and bolts for his attempts, a picture of which is given on this page. At this season of the year we find many of the peculiar, beautiful snow plants just starting from the ground all along the trail; but as we ascend, these disappear, and the trees become smaller, and finally disappear just at the foot of the Saddle. When we emerged from the timber and caught the first glimpse of the Dome and the Saddle, it appeared like an almost vertical wall of smooth rock and impossible to scale.

At this height one easily becomes short of breath, and must make frequent stops to recover the breath. We climbed the projecting spur of the Saddle, with considerable difficulty, and took a long rest upon the comparatively flat surface at the top of this elevation. Two hundred and fifty ft. or more above us dangled the frayed and ragged end of the rope which had been broken at that point, and after extending, with one or two breaks, some 400 or 500 ft. upward, it again terminated, and apparently where it would be most needed.

I had made up my mind before starting that, if possible, I would attempt the ascent, but dared not speak of it to Anderson, fearing that he would not allow it, and when we first came in sight of the place my courage became exceedingly weak, and I was glad that I had not spoken of my intentions to anyone.

After resting a short time, however, I tried to go up a little way, but my boots slipped upon the rocks so that I felt convinced that I could not get up with them on. I then sat down and took off boots and stockings and slung them over my arm for use when I should

reach the top, if I ever did. From this point the slope was too steep for the sharp granite sand to lie upon it, and the rock being perfectly smooth, my bare feet would hold upon it so that I could climb with but little difficulty.

Anderson now seemed to divine my intention, for he came up to me and, after gathering a few of the bolts which had been pulled out and were lying at the foot upon the Saddle, and se-

throw a stone into it, but almost a mile vertically below us, was Mirror lake, while down the valley all the familiar points seemed but a little distance away, but very small. The Cap of Liberty, Mt. Broderick, North Dome, Glacier and Eagle points are all far below us, but in the opposite direction Starr King, Cloud's Rest, Dana, Hoffman and many others tower still farther above us. Near the farther

CLIMBING THE SOUTH DOME, YOSEMITE.

lecting some of the best of the pieces of rope which were still lying there, to repair with, we started up, putting in a bolt here and there, and making the rope fast, for it was almost entirely loose from the point

d of the flat vertical face of the Dome the layers of rock project over. From this point rocks thrown off were 21 seconds by the watch before striking, or rather before the sound came back to us, but it was impossible for me to

SOUTH DOME, YOSEMITE—RESTING ON THE SLOPE.

where it commenced, to its upper end. We added some rope at the lower end, and worked slowly up, not trusting the rope, as it was very weak in many places. Before we had accomplished half the ascent, the clouds which

appreciate the great height. Standing upon this projecting point within a foot of the edge, I did not feel the height much more than I would that of the Palace hotel when looking from the parapet. About 100 ft. back from the face of

ANDERSON'S CABIN, BACK OF SOUTH DOME, YOSEMITE VALLEY.

had been threatening all the forenoon, began to close in around us, and finally a sharp wind began to blow and some flakes of snow and hail to fall, we therefore abandoned the rope and went up the remainder of the distance as fast as we could. At the top I resumed my shoes, as there is nearly 15 acres of comparatively level space there, and at this time there was a large body of snow upon one portion of it. We found the flagstaff fallen down, and set it up, and then the clouds broke away a little and gave us a magnificent view of the valley. Just under our feet, and apparently so near that we could

the rock there is a fissure from 8 to 15 inches in width and this extends for some hundreds of ft., one end running out to the face; the other I did not see. We threw small stones down this fissure and they rattled down from side to side for nine seconds before they found a resting place. This crack is estimated to be from 600 to 800 ft. deep, and if the mass of rock hounded by it is ever detached, it will terminate the existence of the present Mirror lake. We had hardly completed half our hurried inspection when the clouds began to close in around us again.

## Calistoga and Lake County.

The picturesquely situated town of Calistoga is "holding its own and better" at present. It is the terminus of the Napa Valley branch of the C. P. R. R. A large amount of merchandise and other freight is distributed here for mines and towns in Lake county and other interior places. Wool, sulphur and quicksilver are among the products received for San Francisco. Numerous tourists and campers visit this town on their way to Clear Lake and the famous watering places in Lake county. The route via Mt. St. Helena affords many delightful views, and scenery, scarcely less grand and pleasing than that of the Sierra. The hotels are now well patronized.

## The Calistoga Hot Springs.

Eleven of the cottages surrounding the Hot Springs hotel, kept by Col. A. C. Tichenor, have been "made over new," and put in improved order this season, and present a comfortable and home-like appearance. The warm swimming baths are an enjoyable feature. Natural steam and hot sulphur baths are furnished free to guests. The burning gas well is a rare curiosity. Simply an inverted sheet iron tank, about 18 inches deep by 24 in diameter, placed over the well, with two gas burners attached, gathers sufficient gas to give a continuous flame eight inches or more in length. The quality and appearance of the flame is peculiarly different from that of any gas we have ever noticed, and seems worthy of the investigation of our scientists. A large tract of the surrounding fields seems underlaid with steaming hot mineral waters, which find vent through numerous springs. In what might be termed a partially evergreen meadow (which pastures the cows that furnish fresh dairy supplies for the hotel), volumes of steam are to be seen on a cold morning rising up in many different places. Twenty-eight date palm trees, mostly about three ft. in diameter, form a striking feature of the ornamental grounds. They spread their "injun-like" top-knot from 18 to 25 ft. high, reaching above the highest parts of the neat cottages that they were planted for decorating some 15 years ago. A fine growth of elms and other thrifty trees make up a handsome grove. An abundant supply of fresh water is secured to the place, derived from the near hills almost bordering Calistoga on three sides. The place has peculiarly interesting features for the observation of visitors and tourists. Sam. Brannan founded and improved this resort at an expense of over \$200,000, or nearly a quarter of a million. The hotel is located near to and in sight of the railroad depot.

Passing Brannan's great failure and the Colonel's "huge joke" (as some people consider it) concerning the wonderful gold-bearing qualities of the hot spring water, it is safe to say the place has rare advantages that are likely to give it great prominence as a favorite resort for certain months during all four of the seasons. Fisher's Clear Lake and Calistoga Stage Line.

Mr. W. F. Fisher, the proprietor, has the headquarters of this important line of stages at his Lodi stables in the central business portion of Calistoga. He is a practical stage man and has been active in the business about 25 years in Napa and Lake counties. His enterprise is an important business feature of the place and was established over six years ago. He is well credited for employing able and careful drivers, good stock and safe vehicles, and has been fortunate as regards accidents. Good time is made with much regularity over his routes.

His coaches leave Calistoga Tuesdays, Thursdays and Saturdays, for Lakeport, via St. Helena Mountain Toll House, Middletown, Cobb valley, Glenbrook and Keelseyville, returning on alternate days. Connections are made on this route with the Great Western and Oat Hill quicksilver mines; the Anderson, Adams, Siegler, Highland, Allen, Wittier, Pierson and Bartlett springs, Soda Bay and other steamer points on Clear lake. Mondays, Wednesdays and Fridays coaches leave for Sulphur Banks (on the east shore of Clear lake), following the same route to Middletown, and thence via Guenoc and Lower Lake, making connection with Howard and Siegler springs and the steamer on Clear lake. A new graded road will in a few weeks be finished from Bartlett springs to Sulphur Banks, forming new and important connections with this route. Passengers now leave San Francisco at 8 A. M., and reach Lakeport and Sulphur Banks early in the evening, in less than 11 hours from the city, carrying the U. S. mail and Wells, Fargo & Co.'s express.

Fisher's stages connect at Lakeport and Keelseyville with W. C. Van Arman's Cloverdale, Lakeport & Bartlett Springs line. The entire routes of these stages abound in grand and picturesque scenery and natural wonders.

Foster's stages leave Calistoga daily for the celebrated Geysers and other parts of Sonoma county.

There are pleasant drives over good roads about Calistoga, and a greenness and freshness of trees and plants that remind one at this season somewhat of Eastern fields and meadows.

THE dividend of the Ontario mine, Utah, paid on the 15th, amounted to \$75,000. It was the 63th dividend of this mine, aggregating in all the snug sum of \$3,500,000.

It is now estimated that fully 2,000 men are engaged on the Denver & Rio Grande road in Utah.

## DuBOIS' Automatic Quicksilver Feeder.

A machine for feeding quicksilver to the mortars of GOLD MILLS. It is so connected to the cam shaft, that each revolution of the large ratchet wheel, which can be regulated to revolve once in one, two, three or four minutes, as desired, dips a small cup into a reservoir of quicksilver, and by a mechanical movement, empties the contents into a pipe leading down to the mortar, supplying an exact quantity at regular intervals, superseding ordinary hand-feeding, which is of necessity subject to great irregularity, and liable to neglect. It renders the amalgamation of all the gold in the pulp equally certain and perfect. Price complete, \$100.00. Send for circular.

SAN FRANCISCO.

Dissolution of Copartnership.

The partnership heretofore existing between George Spaulding, James Munroe Miller and Dwight Germain, in the City and County of San Francisco, State of California, under the firm name of George Spaulding & Co., is this day dissolved by mutual consent, said James Munroe Miller retiring from said firm.

The new firm of George Spaulding & Co., commencing at this date and being composed of George Spaulding and Dwight Germain are authorized to collect the outstanding and accounts and will pay all claims against the late firm.

Dated at San Francisco this First day of April, 1881.  
The business of Job Printing and Publishing in all its branches will be continued as heretofore by the new firm of George Spaulding & Co., at 414 Clay street.

GEORGE SPAULDING,  
Dwight Germain.

## Excelsior Blasting Powder, —MANUFACTURED BY— THE EXCELSIOR POWDER COMPANY.

This is no NEW PATENT NON-EXPLOSIVE SAFETY POWDER, but the GENUINE STANDARD ARTICLE, and as safe to use and handle as any Nitro-Glycerine Powder manufactured. The Fumes and Oases, common in other Nitro-Glycerine Powders, are almost destroyed, and do not leave the miner with headache or nausea. Among the numerous recent testimonials the following is but a fair sample, constantly received, attesting the superiority of EXCELSIOR POWDER:

AUBURN, Cal., May 26, 1881.—EXCELSIOR POWDER CO.: I send you, per Wells, Fargo & Co., a box containing samples of country rock through which I am running our tunnel on the Conard Mine, and through which we have now run 425 feet, 2 1/2 feet of it having been done with EXCELSIOR POWDER. If any one can produce harder rock I would like to see it. I here say that I can do more execution with your No. 2 Powder in this rock than I can with any No. 1 Powder of any manufacture I have ever used, and I have used every kind now manufactured here, excepting "Tonite," and I have had 20 years' experience in blasting.

Respectfully yours,  
E. W. ROBERTS, Superintendent.  
Give this Powder a trial and you will use no other. For Strength and freedom from noxious fumes, it has no equal. Address all orders to EXCELSIOR POWDER CO., No. 330 Pine Street, Rooms 53 and 54, Academy Building, San Francisco, Cal.

## STEEL CASTINGS

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through this office at published rates.

FROM 1-4 TO 10,000 lbs. WEIGHT.

True to pattern, sound and solid, of unequalled strength, toughness and durability. An invaluable substitute for forgings or cast-iron requiring three-fold strength. Casing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc. 15,000 Orank Shafts and 10,000 Gear Wheels of this Steel now running prove its superiority over other Steel Castings. ORANK SHAFTS, SHOES, DIES and GEARING specialties. Circulars and Price Lists free. Address

## PATENTS AND INVENTIONS.

### List of U. S. Patents for Pacific Coast Inventors.

From Official Reports for the "Mining and Scientific Press," U. S. and Foreign Patent Agents.

FOR THE WEEK ENDING JUNE 14, 1881.

242,738.—DOOR CHECK.—Isaac N. Arment, Dayton, Washington Territory.  
242,868.—HEADER.—J. W. Blewin, Yuba City, Cal.  
243,893.—NITRO DEXTRENE.—O. S. Dean, S. F.  
242,928.—THRUST BEARING FOR PROPELLER SHAFTS.—John Oordon, S. F.  
242,941.—SOPA BED.—F. Laerebans, S. F.  
242,850.—RAILWAY CROSS TIE.—Hans Thielson, Walla Walla, W. T.  
243,015.—HYDRAULIC BORING APPARATUS.—Vaughn & Vincent, Stockton, Cal.  
242,922.—DOOR KNOB ATTACHMENT.—Adam Good, S. F.  
242,776.—BILLIARD CHALK HOLDER.—L. E. Holmes, Woodland, Cal.  
242,746.—SAFETY CADE.—C. D. Brown, Prescott, A. T.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEXTER & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific Coast Inventors transacted with perfect security and in the shortest possible time.

### Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign, Patent Agency, the following are worthy of special mention:

**HYDRAULIC BORING APPARATUS.**—Walter W. Vaughn & George Vincent, San Francisco. Assignor one-half to Asa Clark, of Stockton, and Caleh Doreey, Oakdale, Cal. Dated June 14th. No. 243,015. This invention relates to a hydraulic boring or sinking apparatus, the principle of which is to employ the pressure of water upon the bottom of the pipe to force it into the ground, so that they are enabled to work the pipes or casings for artesian wells by means of a power applied to the bottom of the pipe instead of the top. It consists of an upright framework of posts or pillars supporting the shaft, and fly-wheel operating a series of force pumps, whereby the pressure of water is obtained. An upright, stationary hollow pipe, supported by steady dogs fastened to the pillars, is fastened to the nozzle of the pump pressure-chamber and extends to the ground. Fitting around this hollow pipe is a hydraulic pipe, to the upper end of which a stuffing box and collar is screwed, while to the lower end is screwed a solid metal point, having a steel tip to penetrate the earth. The upper end of this point presents a resisting surface to the water which is forced down through the central stationary pipe. Around this hydraulic pipe fits another pipe, or outside casing, the top of which fits under the collar of the stuffing box, and is pressed down by it. This outside casing, or pipe, extends about half way down the point, and has a flange, or collar, on which a corresponding projection on the point rests. The supporting framework or pillars are braced and strengthened by truss braces and anchor rods, and appropriate pawls support the pipe when hoisting. But the hydraulic pipe and the outside casing pipe are forced down outside the stationary pipe, and are forced into the ground their entire length, after which another length of each may be screwed on and forced down; and when the well or hole is of the required depth, the hydraulic pipe with its point is hoisted out, leaving the outside casing in the ground.

**BILLIARD CHALK HOLDERS.**—Lyle B. Holmes, Woodland, Yolo county. Dated June 14, 1881. No. 242,776. This is a novel device for holding the chalk which is used for billiard cues. The holder is so adjusted that the chalk may be easily brought to the point where it is to be used, and then returned to a position where it will be out of the way. The chalk holder is attached to a cord having a counter-poise or weight, so when the user lets go the handle or holder it will fly back to its place beside the table. A spring in the holder forces the chalk forward as it wears away.

**NITRO-DEXTRENE.**—Gilbert S. Dean, S. F. Dated June 14, 1881. No. 242,893. The object of this invention is the preparation of a new variety of nitro-dextreine. Briefly stated, the manner of its accomplishment consists in treating vegetable fiber with dilute acid whereby its structure is destroyed and dextrination commences, and afterward nitrating the same with cold nitro-sulphuric acid. We shall more fully describe this patent in a future number of the PRESS.

**HEADER.**—J. W. Blewin, Yuba City, Cal. Assignor one-half to J. E. Dempsey, same place. Dated June 14, 1881. No. 242,868. This invention relates to certain improvements in that class of machines for cutting grain and delivering into wagons, known as headers, and consists in certain details of construction and operation, and certain combinations, which improve the header materially, but which it would be very difficult to describe without the aid of suitable engravings.

### News in Brief.

EX-GOVERNOR THOS. L. YOUNG, of Ohio, is en route to California.

ANOTHER batch of discoveries in connection with the star-trover frauds is published.

WILLIAM SHAW drowned himself at Tuceon, A. T., yesterday.

FROST is playing havoc with vegetables at Quebec, Canada.

DEOOLIA's sawmill, near Grass Valley, was destroyed by fire Thursday night.

THE Sunday law was again closely observed in Marysville Sunday.

A CHINAMAN has been ordained at Portland, Or., as a minister in the Baptist Church.

A FIRM at South Bend, W. T., has been fined \$500 for cutting timber on Government land.

TEN eunstrokes, six of them fatal, have occurred at New Orleans since Thursday.

ANOTHER version of the New Testament is to be issued, to be known as the "The American Version."

A FURIOUS and damaging storm swept over a portion of northern Ohio on the night of the 17th inst.

THE Fenians charged with attempting to blow up the Town Hall were committed for trial at Liverpool Saturday.

DURING the 11 months ending May let, the exports of breadstuffs from this country amounted to \$244,955,370.

SERIOUS riots between the French and Italians occurred Sunday at Marseilles, but quiet was finally restored.

A FRIGHTFUL explosion of giant powder occurred at Centerville, near Shasta, demolishing a store and badly injuring the proprietor.

A MAN at Ottawa, Ont., is building an ark and stocking it with provisions, in anticipation of a flood.

WHILE shearing sheep at Antelope, Or., the shears were kicked by a sheep into the side of Frank Driver, killing him immediately.

AT San Diego the railroad company are constructing a huge water-tank, to hold 90,000 gallons.

IMPROVEMENTS of a vast nature are being made in the great National park, in the Yellowstone valley.

THE population of Victoria, B. C., exclusive of Indians, is 6,364, and of the province, about 25,000.

ON Sunday, of last week, the water in patches of a hundred or more yards square, about Tillamook rock light, was black with small fish, upon which millions of birds flocked to feast.

A BARN containing 150 tons of hay, belonging to W. D. Ashley, 10 miles northeast of Stockton, was destroyed by fire Tuesday night. The loss is estimated at \$2,500. No insurance.

TEN more Nihilists have been sentenced at Kief, Russia, to penal servitude, among them four women. The Czar of Russia still keeps himself a close prisoner in his palace, and is said to be a complete wreck.

AS late as 10 days ago there was a heavy fall of snow in several localities of Montana. People call that Territory a good summer country, but such weather as is indicated, enowstorms in June, seems rather too much for the average Pacific Coast man.

THE Gridley Herald is responsible for the story that a sand-hill crane, which was killed near that place recently, was not less than 98 years old. A wire was found around the bird's neck, suspended from which was a silver quarter-dollar, bearing this inscription: "Captured at Fort Du Quesne, May 25, 1873." "Released at Fort Dearbourne November 17, 1846."

THE N. Y. Times has a story from Batavia, N. Y., which town is filled with excitement over the discovery of what are believed to be the remains of Wm. Morgan, the man who betrayed the secrets of the Free Masons in his book entitled "More Mean Illustrations of Masonry," 55 years ago, and was abducted and made away with before the work was given to the public.

A CONSOLIDATION has been effected of the Utah Central, Utah Southern and Utah Extension railroads. Jay Gould, Sydney Dillon, John Sharp and other capitalists connected with the Union Pacific are directors in the new company. The entire line will hereafter be known by the name of the Utah Central. It extends from Ogden to Frisco, a distance of 280 miles, and the probability is that the line will be extended southward to make railway connection in Arizona.

SELF-ADJUSTING BERTHS for steamship use appear to be coming into practical use. It is said that the steamships of the Inman line to Liverpool are to be fitted with a self-adjusting bed, which accommodates itself to every motion, fore and aft and on the beam, which it is possible for a ship at sea to make. The old universal joint contrivance which proved a failure has been disregarded and the principle applied in compass swinging has taken its place in this new invention. The berth occupies only one inch more space than the ordinary stationary berth. The head and foot of the berth are set in a circle of wheels so as to allow the side motion of 30°, and by an arrangement of armatures, a pitch of five inches is allowed. In a steamer 450 ft. long the maximum pitch, by actual test and observation, is only 2½ inches to 6 ft., and the greatest side motion ever observed was 22°, so that the pendulum of this berth is far beyond anything it is ever likely to be tested for.

### Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

IMPORTANT additions are being continually made in Woodward's Gardens. The grove walls d with acacia is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performance. The floral department is resplendent and the wild animals in good view. A day at Woodward's Gardens is a day well spent.

PERSONS receiving a sample copy of the MINING AND SCIENTIFIC PRESS with this notice marked, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We will send it, on trial, at the rate of \$4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

HOW TO STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by letter.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS, which we will sell for \$3 per (half-yearly) volume. In cloth and leather binding, \$5. These volumes, complete, are scarce and valuable for future reference and library use.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus, terms of subscription, etc., and request that they circulate the copy sent.

THE State Mining Bureau, No. 213 Pine street, is open to the public from 10 o'clock A. M. to 5 o'clock P. M. daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

BY TELEPHONE.—Subscribers, advertisers and other persons wishing to address orders, or make appointments with the proprietors or agents by telephone, as we are connected with the central system in San Francisco.

## Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

MANUFACTURERS OF

RAILROAD AND MERCHANT IRON,

ROLLED BEAMS, ANGLE, CHANNEL AND T IRON, BRIDGE AND MACHINE BOLTS, LAG SCREWS, NUTS, WASHERS, ETC., STEAMBOAT SHAFTS, CRANKS, PISTONS, CONNECTING RODS, ETC., ETC.

Car and Locomotive Axles and Frames, and Hammered Iron of Every Description.

HIGHEST PRICE PAID FOR SCRAP IRON.

Orders Solicited and Promptly Executed.

Office, No 202 Market St., UNION BLOCK.

## IRRIGATION! LAND RECLAMATION!

### The Turbine Pumps.

3,000 to 15,000 Gallons a Minute. Strong, Durable & Cheap.

SAN FRANCISCO TOOL CO., No. 21 Stevenson St., San Francisco.

## INCERSOLL ECLIPSE ROCK DRILLS.

The Most Economical Air Compressor in the Market.

## MINERS' HORSE-POWER.

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The Power is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending the drum. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX,  
49 Fremont St., S. F.

## CALIFORNIA Electric Light Company.

Owners of the Brush System of Electric Lighting for the Pacific Coast. Apparatus for sale for Mines, Mills, Manufactories, etc. Plating Machines and Machines for treating Ore manufactured to order. Electric Light furnished on all the principal streets of the city.

Office—No. 119 O'Farrell Street,  
SAN FRANCISCO, CAL.

1881. DEPUTY U. S. MINERAL SURVEYOR.

Surveys for Location or Patent. Maps and Plans Drawn. Mining Properties of all kinds examined and careful reports made of the same. Consultations on Mining Investments. Address, THOS. W. REECE, CIVIL ENGINEER, Oroville, Butte Co., Cal. References given and required.

## Educational.

Boarding and Day School for Boys and Young Men.

Classical and English Courses.

The next session begins Tuesday, July 26, 1881. For information visit the institution, or address

REV. H. E. JEWETT,  
Principal.

### The Berkeley Gymnasium.

A First-Class Academical Institution.

—AFFORDS A—

CLASSICAL, LITERARY, SCIENTIFIC, OR  
BUSINESS EDUCATION.

The Next Term Will Begin July 11th.

For Catalogues or particulars address

JOHN F. BURRIS, Superintendent,  
BERKELEY, CAL.

### CALIFORNIA MILITARY ACADEMY, AT OAKLAND.

The next term will begin on

Monday, July 18, 1881.  
REV. DAVID McCURE, Ph. D.,  
Principal

### MENZO SPRING.

Manufacturer of the Best

Improved Artificial Limbs.

OFFICE AND ADDRESS:

9 Geary Street, Junction of  
Market and Kearny, S. F.

### PEBBLE SPECTACLES.

Muller's Optical Depot,

135 Montgomery St., near Bueh.

SPECIALTY FOR 30 YEARS.

WHOLESALE AND RETAIL.

The most complicated cases of defective vision thoroughly diagnosed, free of charge. Compound Astigmatic Lenses Mounted to order. 24 hours notice.

## TICHENOR'S CALISTOGA HOT SPRINGS,

NAPA COUNTY, CAL. NOW OPEN FOR THE SEASON.

The Proprietor takes pleasure in informing seekers after health and recreation that he has beautified the premises and fashionably known as the CALISTOGA HOT SPRINGS, and placed the main hotel and cottages in perfect order for the reception of guests.

There are 13 two-room cottages, all of which have been newly painted inside and out, and newly plastered and papered. All of these cottages have been supplied with new furniture, bedding, carpets, etc.

The table will be first-class in all respects. The grounds are ornamented with trees, grasses, shrubs and flowers, and are the most suitable of any in the State for children.

There are hot, warm, medium, chemical and vapor baths accessible at all hours of the day and night. There is no staying at all, as the daily train from San Francisco stops 100 yards from the grounds. Time from San Francisco, via Vallejo, 3 1/2 hours; distance, 71 miles, for the most part through Napa Valley—the most charming and delightful in the State.

TERMS—From \$12 to \$16 per week, including any or all baths. Apply or write to

A. C. TICHENOR, Proprietor.

Calistoga, Napa County, Cal.

## MOREY & SPERRY,

MANUFACTURERS OF

### Gold and Silver Grinding and Amalgamating Machinery

HOWLAND'S PULVERIZER Takes the Place of the Cumbrous Stamp Mill and can be put up in one day ready for work.

IT HAS BEEN FULLY PROVED AND TESTED.

It weighs complete, 7,000 pounds. It costs \$1,500 ready for the belt. Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.

Stamp Mills, Rock Breakers, Crushing Rolls, A amalgamating Pans and Separators for Gold and Silver Ores, Chilling Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies Iron Work complete for Wood Frames, also

SPERRY'S  
WROUGHT IRON FRAME  
FOR STAMP MILLS.

Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.

MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

## VULCAN BLASTING POWDER.

—THE MOST ECONOMICAL AND BEST—

Nitro-Glycerine Explosive in the Market.

In the suit of the Giant Powder Co. against the Giant Powder Co. for alleged infringement of Patent, it was held that the Giant Powder Patent was INVALID.

Nos. 1, 2 and 3 Vulcan,

Each grade superior to like numbers of any other Nitro-Glycerine Powder in the market.

VULCAN B. B.,

Superior to Black, Judson or any low grade Powder for Bank Blasts, Railroad work, or any work where Black Powder has been heretofore employed.

TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

The CONSUMER'S COMPANY sell the best Powder at the lowest rates.

Office—218 California St., San Francisco.

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-OLYGERINE PATENTS.

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive

## Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. 24 Triple Force Caps and all Grades of Fuse.

BANDMANN, NIELSEN & CO.,  
SAN FRANCISCO, CAL.

## COKE. PATENT. COKE.

This COKE is exclusively used by Prof. Thomas Price, in his assay office, by the Selby  
Smelting and Lead Co., Prescott, Scott & Co, Risdon Iron and Locomotive Works and others in  
this city. Large supplies are regularly forwarded to consumers in Salt Lake and Nevada, to the  
Copper Queen Mining Co., Longfellow Copper Mining Co. and other consumers in Arizona.  
The undersigned are in receipt of regular supplies from Cardiff, Wales, and offer the COKE  
for sale in quantities to suit purchasers.

BALFOUR, GUTHRIE & CO.,  
316 California St., San Francisco.

## DEWEY & CO.'S

Scientific Press

Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old  
experienced, first-class Agency. We have able and trustworthy associates and Agents in Wash-  
ington and the capital cities of the principal nations of the world. In connection with our edi-  
torial, scientific and Patent Law Library, and record of original cases in our office, we have  
other advantages far beyond those which can be offered home inventors by other Agencies. The  
information accumulated through long and careful practice before the Office, and the frequent  
examination of Patents already granted, for the purpose of determining the patentability of  
inventions brought before us, enables us often to give advice which will save inventors the  
expense of applying for Patents upon inventions which are not new. Circulars of advice sent  
free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

HERCULES POWDER will break more rock, is stronger, safer and better than any other  
Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize  
the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman  
strength. On one occasion he slew several giants who opposed him, and with one blow of  
his club broke a high mountain from summit to base.

**No. 1 XX is the Strongest Explosive Known.**

**No. 2 is superior to any powder of that grade.**

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

## GOLD MINERS

WORKING PLACER, GRAVEL AND QUARTZ MINES,

**SAVE YOUR GOLD!**

— BY USING —

**SILVER PLATED AMALGAMATING PLATES.**

The most economical and successful process now in use. Will warrant my Plates to save a very much larger  
percentage of gold than any other method.

**SWING AND RIFFLE PLATES** for Saving Float Gold Made to Order.

**OLD MINING PLATES BOUGHT, TAKEN IN EXCHANGE FOR NEW, OR RE-PLATED.**

ALL KINDS OF METAL GOODS PLATED!

**San Francisco Gold, Silver and Nickel Plating Works,**

653 and 655 Mission St., bet. New Montgomery and Third, San Francisco.

Send for Circular.

EDWARD G. DENNISTON, PROPRIETOR.

**Awarded First Premium at Every Fair of the Mechanics' Institute  
for the Last Twelve Years.**

**F. VON LEICHT,**

**Mining and Civil Engineer,**

Montgomery Street, San Francisco.

24 Reports, Surveys and Plans of Mines made.

This paper is printed with ink furnished by  
Chas. Eneu Johnson & Co., 509 South 10th  
St., Philadelphia & 59 Gold St., N. Y. Agent  
for Pacific Coast—Joseph H. Dorety, 52  
Commercial St., S. F.

## THE DODGE ROCK BREAKER.

**Challenges the World**

To produce as good and cheap a Machine. Rock Breaker  
and Cornish Rolls combined in one Machine. Pulver-  
izers, to Granulate Ores, for Roasting, Chloridizing,  
Leaching and Concentrating.

**Unequaled Concentrating Machinery!**

FOR CONCENTRATING

**Gold, Silver, Lead and Copper Ores.**

Furnaces for Roasting and Chloridizing Ores, for Amal-  
amation or Leaching.  
Plans, Drawings and Estimates for Working Ores by  
any process.

**M. B. DODGE,**

143 Fremont St., - - San Francisco

## ALEX. DEL MAR,

**Mining Engineer,**

Formerly Director of the Bureau of Statistics of the  
United States; Superintendent of the United States  
Special Commission of Mines; Member of the  
Committee on Mines at the Congress of Na-  
tions held in St. Petersburg, Russia;  
Mining Commissioner for the United  
States Monetary Commission;  
author of a History of the  
Precious Metals, etc.

216 Sansome St., San Francisco.

Mining properties surveyed and reported upon; assays  
and quantitative analyses made of ores, etc.

## Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT  
for DIAMOND POINTED DRILLS, now brought to the  
highest state of perfection, are prepared to fill orders  
for the IMPROVED PROSPECTING AND TUNNELING  
DRILLS, with or without power, at short notice, and  
at reduced prices. Abundant testimony furnished of  
the great economy and successful working of numerous  
machines in operation in the quartz and gravel mines  
on this coast. Circulars forwarded, and full infor-  
mation given upon application.

A. J. SEVERANCE & CO.

Office, No. 320 Sansome street, Room 53.

**RICHARD C. REMMEY, Agent,**

**Philadelphia Chemical Stoneware Manufactory.**

1100 E Cumberland St., Philadelphia, Pa.

Manufacturer of all kinds of Chemical Stone Ware for  
Manufacturing Chemists. Also, Chemical  
Bricks for Clover Towers.

## INDEX TO VOLUME XLII

-OF THE-

## Mining and Scientific Press

From January, 1881, to July, 1881.
